Every thing that regards the motion of *pendulums* has been demonstrated in different ways, since the time of Huygens; and the celebrated Sir Isaac Newton has given us, in his Principia, an admirable theory on this subject, in which he has extended to epicycloids the properties which Huygens had demonstrated in relation to the cycloid.

3. The action of gravity is less in those parts of the earth where the oscillations of the same *pendulum* are slower, and greater where they are swifter.

For the time of oscillation in the cycloid is to the time of perpendicular descent through the diameter of the generating circle, as the periphery of the circle to the diameter.

If then the oscillations of the same *pendulum* be slower, the perpendicular descent of heavy bodies is likewise slower, i. e. the motion is less accelerated, or the force of gravity is less, and conversely.

Hence, as it is found by experiment, that the oscillations of the same *pendulum* are slower near the equator, than in places less remote from the pole; the force of gravity must also be less towards the equator than towards the poles. And consequently, the *figure of the* EARTH is not a just sphere, but a spheroid.

This M. Richer found by an experiment made in the island Cayenna, about four degrees from the equator; where a *pendulum* three feet, eight lines ½ long, which at Paris vibrates seconds, was to be shortened a line and a quarter to reduce its vibrations to seconds.

M. des Hayes, in a voyage to America, confirms the observation of Richer; but adds, that the diminution established by that author appears too little.

M. Couplet the younger, upon his return from a voyage to Brasil and Portugal, falls in with M. des Hayes, as to the necessity of shortening the *pendulum* towards the equator more than Richer has done. He observed, that even at Lisbon the *pendulum* which swings seconds must be two lines ½ shorter than that of Paris; which is shorter than that of Cayenna, as fixed by Richer: though Cayenna be in twenty-four degrees less latitude than Lisbon.

But these observations of M. Couplet did not appear to Sir Isaac Newton to be sufficiently exact. Principia, prop. 20. lib. iii.

The truth is, this diminution does not proceed regularly: Messr. Picart and de la Hire found the length of the *pendulum* which beats seconds exactly the same at Bayonne, at Paris, and at Uranibourg, in Denmark, though the first be in 43½° of latitude, and the last in the latitude 55° 3′.

Hence M. de la Hire takes occasion to suspect, that the diminution is only apparent; and that, e. gr. the iron rod, wherewith M. Richer measured his *pendulum*, might be lengthened by the great heats of the isle of Cayenna: not the *pendulum* shortened by the approach towards the line.

To confirm this, he tells us he found, by very careful experiments, that an iron bar, which exposed to the frost was six feet long, was lengthened two-thirds of a line by the summer's sun.

To this it might be replied, that, according to the table which Sir Isaac Newton has given of the length of the *pendulum* in different latitudes, the difference of the length at 43½° and 55° is so small, that it cannot be easily perceived; because this difference is not above ¼ of a line; and, therefore, the difference at Bayonne and Paris must be still more insensible. With respect to the contraction of *pendulums* by cold, and their dilatation by heat, Newton replies, that in the experiment related by M. de la Hire, the heat of the rod was greater than that of the human body, whereas that of the rod of the *pendulum*, which is not always exposed to the sun, could not be so great; whence he concludes, that the rod of the *pendulum* about three feet long, might be, in reality, a little

longer

longer in ſummer than in winter, and at the equator than in our climates, if we regard merely the heat; but that its dilatation could not be ſo conſiderable as to produce the whole difference obſerved in the length of the *pendulum*. In comparing the different obſervations of the French aſtronomers, Newton apprehends that two lines may be taken for the length by which a ſecond *pendulum* ought to be increaſed at the equator.

From ſome obſervations made by Mr. Campbell, in 1731, at Black-river, in Jamaica, 18° nort. lat. it is collected, that if the length of a ſingle *pendulum* that ſwings ſeconds in London, be 39.126 Engliſh inches, the length of one at the equator, would be 39.00, at the poles 39.206. Phil. Tranſ. Abr. vol. viii. part i. p. 238. or N° 432.

A TABLE, ſhewing how much a *pendulum* that ſwings ſeconds at the equator would gain every twenty-four hours in different latitudes; and how much the *pendulum* would need to be lengthened in theſe latitudes, in order to make it ſwing ſeconds therein.

Latitude of the Place.	Time gained in one Day.		Lengthening of the *Pendulum* to ſwing ſeconds.		Latitude of the Place.	Time gained in one Day.		Lengthening of the *Pendulum* to ſwing ſeconds.	
Deg.	Seconds.		Inch.	Parts.	Deg.	Seconds.		Inch.	Parts.

4. If two *pendulums* vibrate in ſimilar arcs, the times of the oſcillations are in the ſubduplicate ratio of their lengths.

For the time of the oſcillation in the arc LVP *(fig. 33.)* is in a given ratio to the time of the fall through D V, which time is in the ſubduplicate ratio of the ſpace, D V, or of its double C V. the length of the *pendulum*.

Hence the lengths of *pendulums* vibrating in ſimilar arcs are in a duplicate ratio of the times wherein the oſcillations are performed.

5. The numbers of iſochronal oſcillations performed in the ſame time by two *pendulums*, are reciprocally as the times wherein the ſeveral oſcillations are performed.

Hence the lengths of *pendulums* vibrating in ſimilar and ſmall arcs are in the duplicate ratio of the numbers of oſcillations performed in the ſame time, but reciprocally taken.

6. The lengths of *pendulums* ſuſpended between cycloids, are in a duplicate ratio of the times wherein the ſeveral oſcillations are performed.

And hence they are in a duplicate ratio of the numbers of oſcillations performed in the ſame time, but reciprocally taken: and the times of oſcillations in different cycloids are in a ſubduplicate ratio of the lengths of the *pendulums*.

7. If the bodies that oſcillate be acted upon by unequal accelerating forces, then the oſcillations will be performed in times that are to one another in the ratio compounded of the direct ſubduplicate ratio of the lengths of the *pendulums*, and inverſe ſubduplicate ratio of the accelerating forces: becauſe the time of the fall through D V is in the ſubduplicate ratio of the ſpace D V directly, and of the force of gravity inverſely; and the time of the oſcillations is in a given ratio to that time. Hence it appears, that if oſcillations of unequal *pendulums* are performed in the ſame time, the accelerating gravities of theſe *pendulums* muſt be as their lengths: and thus we conclude, that the force of gravity decreaſes as you go towards the equator; ſince the lengths of *pendulums* that vibrate ſeconds are always leſs at a leſs diſtance from the equator.

8. To find the length of a *pendulum*, which ſhall make any aſſigned number of vibrations in any given time.

Let the number of vibrations required be 50 in a minute, and the length of the ſtring, counted from the point of ſuſpenſion, to the centre of oſcillation, be required: it is a fixed rule, that the lengths of *pendulums* are to each other, as the ſquares of their vibrations, and contrariwiſe: now it is agreed, that a *pendulum* vibrating ſeconds (or 60 times in a minute) is 39.128 inches: ſay therefore, as the ſquare of 50 (which is 2500) to the ſquare of 60 (which is 3600); ſo is 39.128 to the length of the *pendulum* required: which will be found 36.34 inches.

Note, in practice, ſince the product of the mean terms will always be 140800.8 (that is, the product of the ſquare of 60, multiplied by 39.128) that is, 3600 × 39.128, you need only divide that number by the ſquare of the number of vibrations aſſigned; and the quotient will give the length of a *pendulum*, which ſhall vibrate juſt ſo many times in a minute.

9. The length of a *pendulum* being known, to find the number of vibrations it will make in a given time.

This being the reverſe of the former; ſay, as the length given, ſuppoſe 36.34, is to the length of the ſtandard *pendulum* ſwinging ſeconds, viz. 39.1285 ſo is the ſquare of the vibrations of the ſtandard *pendulum* in the given time, v. gr. a minute, to the ſquare of the vibrations ſought: that is, as 36.34 : 39.128 :: 3600 : 2500. And the ſquare root of 2500 will be 50, the number of vibrations ſought. But for uſe, here (as in the former problem) you need only divide 140800.8 by the length; and it gives the ſquare of the vibrations, as there you divided by the ſquare of the vibrations to find the length.

On theſe principles, Dr. Derham has conſtructed a table of the vibrations of *pendulums* of different lengths in the ſpace of a minute.

Pend. length in inches.	Vibrat. in a minute.	*Pend.* length in inches.	Vibrat. in a minute.
1	375.7	30	68.6
2	265.6		
3	216.9	39.2	60.0
4	187.8		
5	168.0	40	59.5
6	153.3	50	53.1
7	142.0	60	48.5
8	132.8	70	44.9
9	125.2	80	42.0
10	118.8	90	39.6
20	84.0	100	37.5

Mr. Ferguſon has calculated the following TABLE, ſhewing what the length of a *pendulum* muſt be, to make any given number of vibrations in a minute, from 1 to 300, in the latitude of London.

Vibrations	Length. Yards.	Feet.	Inches.	Vibrations	Length. Feet.	Inches.	Vibrations	Length. Inches.	Vibrations	Length. Inches.	Vibrations	Length. Inches.

Note, These laws, &c. of the motion of *pendulums* can scarce hold strictly; unless the thread that sustains the ball be void of weight, and the gravity of the whole weight be collected in a point.

In practice, therefore, a very fine thread, and a small ball, but of a very heavy matter, are to be used. A thick thread, and a bulky ball, disturb the motion strangely; for in that case, the simple *pendulum* becomes compound; it being much the same as if several weights were applied to the same inflexible rod in several places.

The use of *pendulums* in measuring time in astronomical observations, and on other occasions where a great degree of precision is required, is too obvious to need a description. Either the length of the *pendulum* may be adjusted before its application, and made to vibrate the desired time, v. gr. seconds, half-seconds, &c. by article VI. or it may be taken at random, and the times of the vibrations afterwards determined from article IX.

For the use of the *pendulum* in measuring remote inaccessible distances, &c. by means of sound, &c. see Sound.

Pendulum, *simple*, in *Mechanics*, an expression commonly used among artists to distinguish such *pendulums* as have no provision for correcting the effects of heat and cold from those that have. *Simple pendulum*, or *detached pendulum*, are terms sometimes applied to such *pendulums* as are unconnected with clocks.

Pendulum, *compound*, in *Mechanics*, a *pendulum*, whose rod is composed of two or more wires or bars of metal, that undergo different degrees of expansion and contraction, when exposed to the same heat or cold, and whose *different degrees of expansion* is made to act in such manner as to preserve constantly the same distance between the *point of suspension*, and *centre of oscillation*, although exposed to very different and various degrees of heat or cold. Great are the diversity of contrivances for answering this purpose, but all reducible to the *gridiron*, the *mercurial*, and the *lever pendulum*.

We shall here only observe, that the vulgar method of remedying the inconvenience arising from the extension and contraction of the metalline rods of *pendulums*, is by applying the ball with a screw, by which means the *pendulum* is at any time made longer or shorter, as the ball is screwed downwards or upwards, and thus the time of its vibration is continually the same.

The *gridiron pendulum* was the invention of Mr. John Harrison, a very ingenious artist, and famous for his invention of the clock for finding the difference of Longitude at sea, about the year 1735. It consists of five rods of steel, and four of brass, placed in an alternate order, the middle rod being of steel, and suspending the *pendulum* ball; these rods of brass and steel, thus placed in alternate order, and so connected with each other at their ends, that while the expansion of the steel rods has a tendency to lengthen the *pendulum*, the expansion of the brass rods acting upwards tends to shorten it; and thus when the lengths of the brass and steel rods are duly proportioned, their expansions and contractions will exactly balance and correct each other, and preserve the pendulum invariably of the same length; the simplicity of this ingenious contrivance is much in its favour, and the difficulty of adjustment seems the only objection to it.

Mr. Harrison, in his first machine for measuring time at sea, applied this combination of wires of brass and steel, to prevent any alterations by heat or cold; and in the machines or clocks he has made for this purpose, a like method is used for guarding against the irregularities arising from this cause.

The *mercurial pendulum* was the invention of Mr. Graham, in consequence of several experiments relating to the materials of which *pendulums* might be formed, in 1715. Its rod is made of brass, and branched towards its lower end, so as to embrace a cylindric glass vessel thirteen or fourteen inches long, and about two inches diameter, which being filled about twelve inches deep with mercury, forms the weight, or ball, of the *pendulum*. If upon trial the expansion of the rod be found too great for that of the mercury, more mercury must be poured into the vessel; if the expansion of the mercury exceeds that of the rod, so as to occasion the clock to go fast with heat, some mercury must be taken out of the vessel, so as to shorten the column; and thus may the expansion and contraction of the quicksilver in the glass be made exactly to balance the expansion and contraction of the *pendulum* rod, so as to preserve the distance of the centre of oscillation from the point of suspension invariably the same. Thus, if a glass or metalline tube, uniform throughout, filled with quicksilver, and 58.8 inches long, were applied to a clock, it would vibrate seconds; because it would vibrate in the same time with a simple *pendulum*, whose length is $\frac{1}{4}$ of 58.8 = 39.2 (see

Centre *of oscillation*); and such a *pendulum*, it is evident, admits of a twofold expansion and contraction, viz. one of the metal, and the other of the mercury, which at the same time will be contrary, and correct each other. For the metal expanding with heat, the *pendulum* must vibrate slower on that account; the mercury also expanding with heat, and the length of its column increasing, the centre of oscillation will be raised, and its distance from the point of suspension diminished; and on this account, the *pendulum* will vibrate quicker. Therefore, if the circumstances of the tube and mercury are skilfully adjusted, the time of the clock might, by these means, for a long course of time, continue the same, without any sensible loss or gain. Mr. Graham, who made a clock of this sort, compared it with one of the best of the common sort for three years together, and found the errors of the former about one-eighth part of the latter. Phil. Trans. N° 392.

The *lever pendulum*. From all that we can collect respecting this construction of a *pendulum*, we are inclined to believe, that the idea of making the difference of the expansion of different metals operate by means of a lever, originated with Mr. Graham, who, in the year 1737, constructed a *pendulum*, whose rod was composed of one bar of steel between two of brass, and acting upon the short end of a lever, to the other end of which, the ball or weight of the *pendulum* was suspended: this *pendulum* was, upon trial, found to move by jerks, and laid aside by Mr. Graham, to make way for the mercurial *pendulum*.

Mr. Short (Phil. Trans. vol. xlvii. art. 88.) informs us, that Mr. Frotheringham, a quaker in Lincolnshire, caused a *pendulum* of this kind to be made, consisting of two bars, one of brass, and the other of steel, fastened together by screws, with levers to raise or let down the bob; and that these levers were placed above the bob. M. Cassini, in the History of the Royal Academy of Sciences at Paris, for 1741, also describes two sorts of *pendulums* for clocks, compounded of bars of brass and steel, and in which he applies a lever to raise or let down the bob of the *pendulum*, by the expansion or contraction of the bar of brass.

Mr. John Ellicott, in the year 1738, constructed a *pendulum* on the same principle, but differing from Mr. Graham's in many particulars: the rod of Mr. Ellicott's *pendulum* was composed of two bars only, the one of brass, the other of steel; it had two levers, each sustaining its half of the weight or ball, and a spring under the lower part of the ball, to relieve the levers from a considerable part of its weight, so as to render their motion more smooth, and safer: the one lever in Mr. Graham's construction was above the ball; both the levers in Mr. Ellicott's were within the ball, and each lever was furnished with an adjusting screw, in order to lengthen or shorten the lever, so as to render the adjustment the more perfect. Phil. Trans. vol. xlvii. p. 479, &c. where Mr. Ellicott's methods of construction are described and illustrated by figures.

Great ingenuity has been displayed by these very eminent artists on this construction; but we must further observe, in the history of improvements of this nature, that Mr. Cumming, another eminent artist, has given, in his Essays on the Principles of Clock and Watch-work, London, 1766, an ample description, with plates, of a *construction of a pendulum with levers*, in which he seems to have united the properties of Mr. Graham's and Mr. Ellicott's, without any of the defects of either. The rod of his *pendulum* is composed of one flat bar of brass, and two of steel, steadily supporting each other, but in such manner, that each bar has its whole surface exposed to the air, so as to feel each change in its temperature at the same instant. He uses *three levers* within the ball of the *pendulum*, with a transparent glass before, and a silvered glass behind the levers, by which they are secured from dust, &c. and the back pivots, and other back parts of the lever, are constantly exposed to view, as well as the front side, one of the levers serving to render the pressure of the ball on each of the other two perfectly equal, notwithstanding any imperfections of execution, or inequalities that may take place in the length of those levers, if the one adjusting screw should happen to be more turned than the other: by means of this third lever the ball of the pendulum is always enabled to accommodate itself to the sides of the rod on which it moves, so as to slip freely thereon, without the possibility of jamming, or moving by jerks; the adjusting screws are so constructed, that no bad effect can arise from any bending of the screw, or from irregularity in its threads; nor can they be moved by any accident, after they have been properly adjusted. In this construction also, the spring, which relieves the levers from the pressure of the ball, is upwards of twenty inches long, in a spiral form,

and contained in a cylindric cavity within the ball, when it can, after all the parts of the *pendulum* are put together, and applied to the clock, be brought to such a degree of tension as to sustain any desired part of the weight of the ball, and render the motion of the lever perfectly free; the levers also are so disposed of, as to admit of their being much longer than in Mr. Ellicott's construction, by which means their angular motion and friction on the pivots are proportionably diminished; and for the more accurate adjusting of this *pendulum* to mean time, it is provided with a small ball and screw below the principal ball or weight, one entire revolution of which on its screw will only alter the rate of the clock's going one second per day; and its circumference divided into 30, one of which divisions will alter its rate of going one second in a month.

PENDULUM *clock*, a clock which has its motion regulated by the vibration of a *pendulum*.

It is controverted between Galileo and Huygens, which of the two first applied the *pendulum* to a clock. For the pretensions of each, see CLOCK.

After Huygens had discovered, that the vibrations made in arcs of a cycloid, however unequal they were in extent, were all equal in time; he soon perceived, that a *pendulum* applied to a clock, to as to make it describe arcs of a cycloid, would rectify the otherwise unavoidable irregularities of the motion of the clock; since, though the several causes of those irregularities should occasion the *pendulum* to make greater or less vibrations, yet, in virtue of the cycloid, it would still make them perfectly equal; and the motion of the clock governed thereby, would therefore be preferved perfectly equable.

But the difficulty was to make the *pendulum* describe arcs of a cycloid; for, naturally, the *pendulum* being tied to a fixed point, can only describe arcs of circles about the same.

Here M. Huygens contrived to fix the iron rod or wire, which bears the bob or bottom, at the top to a silken thread, placed between two cycloidal cheeks, or two little arcs of a cycloid, made of metal. Hence the motion of vibration, applying incessantly from one to the other of those arcs, the thread, which is extremely flexible, eaſily aſſumes the figure thereof; and by means hereof it is demonſtrated, that the weight ſuſpended at the other end of the rod will deſcribe a juſt arc of a cycloid.

This is doubtleſs one of the moſt uſeful and ingenious inventions many ages have produced: by means whereof, we have clocks which will not err a ſingle ſecond in ſeveral days.

It is true, the *pendulum* is ſtill liable to its irregularities, how minute ſoever they may be; and M. de la Hire thinks there is ſtill room to improve it.

The ſilk thread by which it is ſuſpended, he obſerves, ſhortens in moiſt weather, and lengthens in dry; by which means the length of the whole *pendulum*, and conſequently the times of the vibrations, are ſomewhat varied.

To obviate this inconvenience, M. de la Hire, inſtead of a ſilk thread, uſed a little fine ſpring; which was not indeed ſubject to ſhorten and lengthen, but which he found grew ſtiffer in cold weather, and then made its vibrations falter than in warm.

He had therefore recourſe to a ſtiff wire or rod, firm from one end to the other. In fact, by this means he renounced the advantages of the cycloid; but he found, as he ſays, by experience, that the vibrations in arcs of circles are performed in times as equal, provided they be not of too great extent, as thoſe in cycloids. But the experiments of Sir J. Moor, and others, have demonſtrated the contrary.

The ordinary cauſes of the irregularities of *pendulums*, Dr. Derham aſcribes to the alterations in the gravity and temperature of the air, which increaſe and diminiſh the weight of the ball, and by that means make the vibrations greater and leſs; an acceſſion of weight in the ball being found by experiment to accelerate the motion of the *pendulum*.

A weight of ſix pound added to the ball, Dr. Derham found, made his clock gain 15 ſeconds every day.

A general remedy againſt the inconveniencies of *pendulums* is to make them long, the bob heavy, and to vibrate but a little way; this is the uſual means in England; the cycloidal cheeks being generally overlooked. See the preceding article.

Pendulum clocks reſting againſt the ſame wall have been found to influence each other's motions. See the Phil. Tranſ. N° 453, ſect 5 and 6, where Mr. Ellicot has given a very curious and exact account of this phenomenon.

PENDULUM *clocks, to correct the motion of.* The uſual method is to ſcrew and ſet down the ball; but a very ſmall alteration here having a very great effect, Dr. Derham prefers Huygens's method, which is to have a ſmall weight or bob to ſlide up and down the rod above the ball, which is to be immoveable; though he improves on the method, and recommends having the ball to ſcrew up and down, to bring the *pendulum* near its gage; and the little bob to ſerve for the nicer corrections, as the alteration of a ſecond, &c.

Mr. Huygens orders the weight of this little corrector to be equal to that of the wire, or $\frac{1}{50}$ of that of the great ball; he adds a table of the alterations the ſeveral ſtiffnings thereof will occaſion in the motion of the *pendulum*; wherein it is obſervable, that a ſmall alteration towards the lower end of the *pendulum*, makes as great an alteration in time, as a greater riſing or failing does when higher.

PENDULUM *royal*, a name given among us to a clock, whoſe *pendulum* ſwings ſeconds, and goes eight days; ſhewing the hour, minute, and ſecond.

The numbers of ſuch a piece are thus calculated: firſt caſt up the ſeconds in twelve hours, which are the beats in one turn of the great wheel; and you will find them to be $43200 = 12 \times 60 \times 60$. The ſwing-wheel muſt be 30 to ſwing 60 ſeconds in one of its revolutions; now let $\frac{1}{2}$ of $43200 = 21600$ be divided by 30, and you will have 720 in the quotient, which muſt be broken into quotients; the firſt of them muſt be 12 for the great wheel, which moves round once in twelve hours. 720 divided by 12, gives 60, which may alſo be conveniently broken into two quotients, as 10 and 6, or 5 and 12, or 8 and 7½; which laſt is moſt convenient; and if you take all your pinions 8, the work will ſtand thus:

$$\left.\begin{matrix} 8) & 96 & (12 \\ 8) & 60 & (8 \\ 8) & 30 & (7\frac{1}{2} \end{matrix}\right\} 1$$

30

According to this computation, the great wheel will go about once in twelve hours, to ſhew the hour; the ſecond wheel once in an hour, to ſhew the minutes; and the ſwing-wheel once in a minute, to ſhew the ſeconds. See CLOCK-WORK.

PENDULUM *level*. See LEVEL.

PENDULUM *watch*. See WATCH.

PENETRABILITY. See IMPENETRABILITY.

PENETRALE, among the Romans, properly denoted the chapel conſecrated to the PENATES, or houſhold gods.

PENETRATION, *penetratio*, the act whereby one thing enters another, or takes up the place already poſſeſſed by another.

The Schoolmen define *penetration* the co-exiſtence of two or more bodies, ſo that one is preſent, or has its extenſion in the ſame place as the other.

Philoſophers hold the *penetration* of bodies abſurd, i. e. that two bodies ſhould be at the ſame time in the ſame place; and accordingly, impenetrability is laid down as one of the eſſential properties of MATTER.

What we popularly call *penetration* only amounts to the matter of one body's being admitted into the vacuity of another. Such is the *penetration* of water through the ſubſtance of WOOD.

PENGUIN, in *Ornithology*, a name given by ſailors of different nations to two different ſpecies of water-fowl, both web-footed, and both wanting the hinder toe.

The *penguin* of the Engliſh is the bird more commonly known by the name of the *gare-fugel*, or the *alca impennis* of Linnæus.

It grows to the ſize of a common tame gooſe, and is black on its back, or upper part, and white on the belly; its wings are very ſmall, and by no means fit for flying; its beak is ſomewhat broad and long, compreſſed on the ſides and back, and has toward the extremity ſeveral furrows, ſeven or eight on the upper ſide, and about ten on the under; and the long cheap ſwells into a protuberance downward; its head has two white lines reaching from the beak to the eyes; its tail is very ſhort, and it has no hinder toe.

This bird is obſerved by ſeamen never to wander beyond ſoundings; and according to its appearance they direct their meaſures, being then aſſured that land is not very remote. This bird breeds in the iſle of St. Kilda, appearing there in the beginning of May, and retiring in the middle of June. It lays one egg, about ſix inches long, of a white colour. See *Tab.* IV. *Birds*, N° 46.

The *penguin* of the Dutch is the *anſer Magellanicus* of Clufius. See PINGUIN.

PENGUIN, or *wild* ANANAS, *karatas*, in *Botany*. Its characters are theſe: it hath a tubulous bell-ſhaped flower, divided into three parts at the mouth, from whoſe calyx ariſes the pointal, fixed like a nail in the hinder part of the flower, which afterward becomes a fleſhy, almoſt conical fruit, divided by membranes into three cells, which

are full of oblong seeds. Linnæus has joined the *karota* and *mamma* to the *bromelia*.

This plant is very common in the West Indies, where the juice of its fruit is often put into punch, being of a sharp acid flavour. There is also a wine made of the juice of this fruit, which is very strong, but it will not keep good long, so is only for present use. This wine is very intoxicating, and heats the blood, therefore should be drank very sparingly. In England this plant is preserved as a curiosity; for the fruit seldom arrives to any degree of perfection for use in this country, though it often produces fruit in England, which has ripened pretty well; but if it were to ripen as thoroughly here as in its native country, it will be little valued, on account of its great austerity, which will often take the skin off from the mouths and throats of those people who eat it incautiously. Miller.

PENICILLA, thus called from *penicillus*, a *pencil*, which it is supposed to resemble in shape, in *Pharmacy*, a LOZENGE; or form of medicine made round by rolling.

PENICILLI *marini*, in *Natural History*, a sort of marine tubuli, or cases of sea-worms, making a distinct genus of those shells. They are defined to be shelly tubes, very slender, and terminating in the shape of a painter's pencil; many of them in their native shape adhering to stones, &c. on the sea-shores, by means of a soft and lax substance. Some of these are white and pellucid, others yellowish or brown; and the more common sort are about a finger's length, and about the thickness of a wheaten straw; and some are of a sort of funnel-like shape, and have their mouths surrounded by a sort of hairs, or filaments. These are called by some *proboscipsellum*, others are called *cauli*, and others *retalia*.

PENICILLUS, among *Surgeons*, is used for a TENT, to be put in wounds, or ulcers.

PENIDIUM, in *Pharmacy*, *loaf-sugar*.

Dr. Quincy uses the word *penidium*, for a kind of clarified sugar, with a mixture of starch, made up into little lumps.

PENINSULA, in *Geography*, a portion or extent of land, joining to the continent by a narrow neck or isthmus; the rest being encompassed with water.

The word is compounded of the Latin *pene* and *insula*, q. d. *almost island*, which the French pertinently enough render *presque-isle*.

Such is Peloponnesus, or the Morea; such also are Africa, Jutland, &c.

Peninsula is the same with what is otherwise called CHERSONESUS.

PENIS, in *Anatomy*, a part of the body, called, by way of eminence, the *member*, or *virile member*, as being one of the principal organs of generation in the male kind. See *Tab. Anat. (Splanch.) fig.* 1. *lit.* 2. *fig.* 8. *lit.* e b, &c. *fig.* 10. *lit.* d. *fig.* 13. *lits* c e, n n. *(Angeiol.) fig.* 1. *n.* 67.

It is fastened to the lower part of the os pubis, and the upper part of the scrotum; its body consists of the two corpora cavernosa, the corpus cavernosum urethræ, and the urethra itself.

The *corpora* CAVERNOSA *of the penis*, called also *corpora nervosa & spongiosa*, &c. have two distinct origins in the os pubis; whence they proceed, growing both in bulk and thickness, till they meet the *corpus* CAVERNOSUM of the urethra, where they join; leaving an interstice or channel for its passage along them; and thus they continue their progress, connected together by a membranous body called the *septum*, and terminating at length in the glans.

The *cavernous body of the urethra* includes the urethra or urinary passage. Its form, contrary to that of the other cavernous bodies, is largest at the two extremes, and smallest in the middle. That part included between the two origins of the cavernous bodies of the *penis*, Mr. Cowper calls the *bulb of the urethra*; its other extremity, being dilated, forms the body called the *glans*.

The *penis* receives arteries from the internal iliac branches, and umbilical arteries; and these at length subdividing into innumerable branches, from the capillary extremities thereof arise so many veins, in whose channels are apertures corresponding to so many cells, which, communicating with each other, empty themselves into larger [illegible] ducts, running on the superior surface of the *penis*; from whereof join the veins of the prepuce; others make one large trunk, called *vena penis*, which, reaching on the dorsum *penis* to the prostate, there divides, and enters the internal iliac on either side.

The *penis* has nerves from a trunk compoied of a coalescence of the third of the os sacrum, and a branch of the great crural: these, ascending the cavernous bodies, expand themselves over the upper surface thereof, and are thence distributed to all parts of the *penis*.

It has lymphaducts very numerous on its surface under the skin, which discharge themselves into the glandulæ inguinales.

The *penis* has two pair of muscles, and an odd one; the odd muscle is called ACCELERATOR *urinæ*.

The first pair of muscles are called the *erectores penis*. By their action the *penis* is sustained, and drawn towards the pubes; and, by the assistance of the suspensory ligament of the *penis*, the *vena penis* is applied to the transverse ligament of the ossa pubis, and the refluent blood hindered from passing that way, whereby the corpora cavernosa become distended.

The last pair of muscles are the *transversales penis*, which vary in various subjects, and are sometimes wanting: their use is to dilate that part of the cavernous body of the urethra, to which they are fastened.

The *penis* has also three glands, first discovered by Mr. Cowper; these all empty themselves into the urethra, and, from the tenacity of the liquor they separate, are called the MUCOUS *glands*. See also *Observations* GLANDS.

The whole compages of the *penis* is invested with a cellulose membrane, of admirable texture; which again is covered with a firm nervous coat, and that with a cuticula and cutis; the duplicature of the cutis on the glans makes the prepuce.

It is tied to the lower part of the glans by a ligament called the FRENUM. By another ligament, called *suspensorium*, the *penis* is held up to the ossa pubis.

The use of the *penis* is for evacuating the seed and urine. Indeed, Dr. Drake, from a view of its structure, thinks it originally intended for the former only; and that the conveyance of the urine was not considered by nature in the mechanism of this part.

He adds another use, viz. the incitement to venery, and the propagation of the species. In effect, without such an instrument, the seed of the most perfect animals could not be conveyed to the place of prolification: add to this, that an alternation of erection and flaccidity is absolutely necessary; the first for the performance of its office, the second for the security of the part. See ERECTION.

The cavernous body of the urethra is erected by the musculi accelatores, embracing the veins of its bulb.

Bleeding in the vena dorsalis of the *penis* is usually found to surpass all remedies whatever in abating inflammatory disorders of this member. This large vein, which runs along the back or upper side of the *penis*, being generally pretty much distended and conspicuous in an inflammation of this part, may be opened about the middle, and kept bleeding till the member becomes flaccid, and a sufficient quantity of blood be discharged proportionably to the urgency of the case; which done, a compress must be applied, and kept on by bandage. There must, however, be great caution in this operation not to injure the arteries or nerves which enter the *penis* near this vein, as also not to make the bandage too strict, by which the inflammation and symptoms may become worse than before. Heister's Surgery, p. 284.

PENIS *primus musculus*, in *Anatomy*, a name given by Vesalius and others, to a muscle of the *penis*, now generally known by the name of ACCELERATOR.

PENITENCE, *pœnitentia*, is sometimes used for a state of repentance, and sometimes for the act of repenting. See REPENTANCE, and IMPENITENCE.

PENITANCE is also used for a discipline, or punishment attending repentance; more usually called PENANCE.

PENITENCE also gives the title to several religious orders, consisting either of converted debauchees, and reformed prostitutes; or of persons who devote themselves to the office of reclaiming them. Of this latter kind is the *Order of* PENITENCE *of St. Magdalen*, established about the year 1272, by one Bernard, a citizen of Marseilles, who devoted himself to the work of converting the courtezans of that city.

Bernard was seconded by several others; who, forming a kind of society, were at length erected into a religious order by pope Nicholas III. under the rule of St. Augustine.

F. Gesnay adds, that they also made a religious order of the *penitents*, or women they converted, giving them the same rules and observances which they themselves kept.

Congregation of PENITENCE *of St. Magdalen at Paris*, owed its rise to the preaching of F. Tiseran, a Franciscan, who converted a great number of courtezans about the year 1492. Louis, duke of Orleans, gave them his house for a monastery; or rather, as appears by their constitutions, Charles VIII. gave them the hotel, called Bochaigne, whence they were removed to St. George's chapel, in 1572. By virtue of a brief of pope Alexander, Simon, bishop of Paris, in 1497, drew them up a body of statutes, and gave them the rule of St. Augustine.

To qualify a woman for admission, it was required, that the

she had committed the sin of the flesh. None were admitted who were above thirty-five years of age.

Till the beginning of the last century, none but *penitents* were admitted; but since its reformation by Mary Alexquio, in 1618, none have been admitted but maids, who, however, still retain the ancient name *penitents*.

PENITENTS, an appellation given to certain fraternities, or societies of persons who assemble together for prayers, make processions bare-footed, their faces covered with linen, and give themselves discipline, &c.

There are *White Penitents* in Italy, at Avignon, and at Lyons. There are also *Blue Penitents*, and *Black Penitents*, which last assist criminals at their death, and give them burial.

PENITENTS, or *Converts of the name of Jesus*, a congregation of religious at Seville, consisting of women, who had led a licentious life, founded in 1550.

This monastery is divided into three quarters: one for professed religious; another for novices; a third for those under correction.

When these last give signs of a real repentance, they are removed into the quarter of the novices, where, if they do not behave themselves well, they are remanded to their correction. They observe the rule of St. Augustine.

PENITENTS *of Orviete*, are an order of nuns, instituted by Antony Simonetti, a gentleman of Orviete. The monastery he built was at first destined for the reception of poor girls, abandoned by their parents, and in danger of losing their virtue.

In 1662 it was erected into a monastery, for the reception of such as, having abandoned themselves to impurity, were willing to take up, and consecrate themselves to God by solemn vows. Their rule is that of the Carmelites.

These religious have this in peculiar, that they undergo no noviciate. All required is, that they continue a few months in the monastery in a secular habit; after which they are admitted to the vows.

PENITENTIAL, *Pœnitentiale*, an ecclesiastical book, retained among the Romanists; wherein is prescribed what relates to the imposition of penance, and the reconciliation of *penitents*.

To the Capitulars of Charlemagne, the priests are enjoined to study well their *Penitentials*. There are various *Penitentials*, the Roman *Penitential*, that of Venerable Bede, that of pope Gregory III, &c.

PENITENTIARY, *pœnitentiarius*, an office, or tribunal, in the court of Rome, wherein are examined, and delivered out, the secret bulls, graces, or dispensations, relating to conscience, confession, &c.

The expeditions of the *penitentiary* are sealed up with red wax, and sent close; directed to the confessors.

PENITENTIARY is also an officer, or dignitary, in some cathedrals, vested with power from the bishop to absolve in cases reserved to him; on which account he is also called the *bishop's ear*.

In some places there is a *grand penitentiary*, and a *subpenitentiary*. Anastasius says, that pope Simplicius chose some among the Roman priests to preside over penitences. At present the pope has his *grand penitentiary*, who is a cardinal, and the chief of the other *penitentiary priests* established in the patriarchal churches of Rome, who consult him in all difficult cases.

He presides in the *penitentiary*, dispatches dispensations, absolutions, &c. and has under him a regent, and twenty-four proctors, or advocates of the facted *penitentiary*.

PENITENTS, in the church of Rome. See POENITENTES.

PENNANT, or PENDANT, in a *Ship*. See PENDANT.

PENNATA *folia*, winged leaves, among *Botanists*, are such leaves of plants as grow directly one against another, on the same rib or stalk: as those of ash, walnut-tree, &c. See LEAF.

PENNATULA, in *Natural History*. See SEA-PEN.

PENNEVISCH, in *Ichthyology*, a name given by some to the most common species of the fish called BAGRE, caught in the East and West Indies.

PENNON, or PENON, a standard with a long tail, anciently belonging to a simple gentleman; properly used as a guidon, to place over a tent.

It is opposed to the *banner*, which was square; and hence, when any one was to be made a banneret, the ceremony consisted in cutting off the tail of his *pennon*, and thus converting it into a banner.

PENNY, or PANY, in *Commerce*, an ancient English coin, which had formerly considerable course; but is now dwindled into an imaginary money, or money of account.

It is derived by Camden from *pecunia*; but others suppose that the word is formed from *pende, to weigh*, and it was sometimes written according to this origin, *pending*.

The ancient English *penny*, *penig*, or *pening*, was the first silver coin struck in England: nay, and the only one current among our Saxon ancestors; as is agreed by Camden, Spelman, Dr. Hickes, &c.

With them it was always the 240th part of their pound, and the true weight should have been about 22½ Troy grains. Some writers affirm, that the Saxons had likewise a half-penny and farthing, both of them probably of silver. Clarke on Coins, p. 248.

The *penny*, which in Ethelred's time was the 20th part of the Troy ounce, was equal in weight to our three-pence; five of them made one shilling, or sculling Saxon; and thirty a mark or mancuse, equal to our 7s. 6d. It was the largest silver coin in England, and retained this value till the reign of Edward III.

Till the time of king Edward I. the *penny* was struck with a cross so deeply indented in it, that it might be easily broke, and parted, on occasion, into two parts; thence called *half-pennies*; or into four, thence called *fourthings*, or *farthings*. But that prince coined it without indenture; in lieu of which he first struck round *half-pence* and farthings.

Stow, in his Annals, p. 290, observes, that *half-pennies* were first coined round, A. D. 1270, in the reign of Edward I. But historians have since discovered, that *half-pennies* of this kind were coined by Henry I. and that though the usual way in the reign of the two first Williams was to cut the *penny* into two for making of *half-pennies*, &c. yet it has been supposed that some few *half-pennies* might even then be coined round. Some few pieces of this kind are preserved in the cabinets of the curious. See Mr. Pegge's remarks on this subject in Gent. Mag. vol. xxvii. p. 104, &c.

Edward I. also reduced the weight of the *penny* to a standard; ordering that it should weigh thirty-two grains of wheat, taken out of the middle of the ear. Stat. 25 Edw. I. This *penny* was called the *penny sterling*. Twenty of these pence were to weigh an ounce, whence the *penny* became a weight, as well as a coin.

By 9 Edw. III. it was diminished to the twenty-fifth part of the Troy ounce; by 2 Hen. VI. it was the thirty-second part; by 5 Edw. IV. it became the fortieth, and also by 30 Hen. VIII. and afterwards the forty-fifth; but by 2 Eliz. sixty *pence* were coined out of the ounce, and during her reign fifty-two, which proportion is observed in our times.

The *penny sterling* is now disused as a coin, and hence subsists, but as a money of account, containing the twelfth part of a shilling, or the two hundred and fortieth part of a pound.

The course of exchange between England and France is settled on the foot of so many pence sterling, for a French crown of three livres.

The French *penny*, or denier, is of two kinds; the Paris *penny*, called *denier Parisis*; and the *penny* of Tours, *denier Tournois*. See DENIER.

The Dutch *penny*, called *penninck*, or *pening*, is a real money, worth about one fifth more than the French *penny Tournois*. The *penninc* is also used as a money of account, in keeping books by pounds, florins, and patards; twelve *penincs* make the patard; and twenty patards the florin.

At Hamburgh, Nuremberg, &c. the *pend* or *pfennig* of account is equal to the French *penny Tournois*. Eight of them make the kreutz; and forty the florin of those cities; and ninety the French crown, or 4s. 6d. sterling. See COIN.

PENNY, in *Ancient Statutes*, &c. is used for all silver money.

And hence the *two-penny*, *three-penny*, *hundred-penny*, *tithing-penny*, and *brithwal-penny*. See PENCE, &c.

PENNY-*earth*, in *Agriculture*, a term used by the farmers for a hard, loamy, or sandy earth, with a very large quantity of sea-shells intermixed in it; some of which being round and flat, and in some measure resembling pieces of money, have occasioned the earth's being called by this name. It is an earth not easily dug; but is usually undermined with pick-axes, and then falls in large lumps; which, with the shells, break to pieces, and leave the shells loose. It is prepared by breaking and mixing well with water, and then makes very desirable floors. The Jersey coursers comb-pots are also made of it, and the sides and tops of ovens are plastered with it; and being slightly managed, it combines into a coat almost as strong as plaister of Paris.

PENNY *bird*, *half*. See BIRD *half-penny*.

PENNY, *half*. See HALF-*penny*.

PENNY, *rere*. See RERE-*penny*.

PENNY, *shan*. See SCHAN-*penny*.

PENNY, *ward*. See WARD-*penny*.

PENNY *post*. See POST.

PENNY-*royal*, *pulegium*, in *Botany*. Its characters are these: the empalement of the flower is permanent, cut into

five parts; the flower is of the lip-kind; it hath one petal, with a short tube, divided at the brim into four parts; the helmet, or upper lip of the flower, is entire; the lower is cut into three equal segments; it hath four stamina, two being longer than the other, terminated by roundish summits, and a four-pointed germen, supporting an erect style, crowned by a bifid stigma; the germen afterward becomes four small seeds, sitting in the empalement of the flower. Miller enumerates three species.

Tournefort and Linnæus make the *penny-royal* a species of *menthæ*, or MINT.

The several sorts of *penny-royal* all propagate themselves very fast by their trailing branches, which take root at every joint; so that no more is required in their culture and propagation than to cut off and plant out these rooted branches: they should be planted at a foot distance every way, that they may have room to grow. The best season for this is in September, that the plants may be rooted before winter. They love a moist soil, and generally grow very fast.

Penny-royal is among the first plants in esteem in the present practice, as well as in former ages, as an attenuant and uterine. It promotes the menses, and forwards delivery. It is good in flatulencies and suppressions of urine, and by many is greatly recommended in dropsies, jaundices, and other chronic distempers. It communicates its virtues very readily to water in infusion; and its simple water, drawn by the alembic, has, perhaps, more virtue than any other kept in the shops. Its essential oil is sometimes, though rarely, used in the same intentions with the water.

The oil, and a simple and spirituous water strongly impregnated with it, by drawing off a gallon of water, or proof spirit, from a pound and a half of the dry leaves, are kept in the shops.

PENNY-*royal, Virginian*, a species of *satureia*. See SAVORY.

PENNY-*weight*, a Troy WEIGHT, containing twenty-four grains; each grain weighing a grain of wheat gathered out of the middle of the ear, well dried.

The name took its rise hence, that this was actually the weight of one of our ancient silver *pennies*.

Twenty of these *penny-weights* make an ounce Troy. A *penny-weight* of gold bullion standard, is worth four shillings; and of silver bullion, threepence. See GOLD and SILVER.

PENNY-*wort*. See NAVEL-*wort*.

PENNY-*wort, marsh* and *water*, *hydrocotyle*, in *Botany*, the name of a genus of plants of the *pentandria digynia* class; the characters of which are these: the flowers are disposed into small umbels, and are of the rosaceous kind, being composed of several petals, arranged in a circular order upon a cup, which afterwards becomes a fruit composed of two plain and semi-orbicular seeds.

The species of *hydrocotyle*, enumerated by Linnæus, are five.

PENON. See PENNON.

PENSA *libra*, in our *Ancient Customs*, a pound of money paid by weight, not by tale.

PENSILES *horti*, in *Antiquity*, gardens raised on arches by Nebuchadnezzar, king of Babylon, in order to gratify his wife Amytis, daughter of Astyages, king of Media. Q. Curtius makes them equal in height to the walls of the city, viz. fifty feet. They contained a square of four hundred feet on every side, and were carried up into the air in several terrasses, laid above one another, and the ascent from terrass to terrass was by stairs ten feet wide. The arches sustaining the whole pile were raised above one another, and it was strengthened by a wall, surrounding it on every side, of twenty-two feet in thickness. The floors of each of the terrasses were laid in the following manner: on the top of the arches were first laid large flat stones sixteen feet long, and four broad, and over them was a layer of reed, mixed with a great quantity of bitumen, over which were two tows of bricks closely cemented together by plaister, and over all were laid thick sheets of lead; and, lastly, upon the lead was laid the mould of the garden. The mould, or earth, was of such a depth, as to admit the largest trees to take root and grow; and it was covered with various kinds of trees, plants, and flowers. In the upper terrass there was an aqueduct or engine, whereby water was drawn up out of the river, for watering the whole garden. Diod. Sic. lib. ii. Strab. lib. xvi. Q. Curtius, lib. v. cap. 1, or, Prid. Conn. vol. i. p. 144.

PENSION, *pensio*, a yearly appointment, or sum of money paid any one for services or considerations already past.

That which in the two Temples is called a *parliament*, and in Lincoln's Inn a *council*, is in Gray's Inn termed a *pension*; viz. an assembly of the members of the society, to consult of the affairs of the house.

PENSIONS also denote certain annual payments of each member to the house, for certain occasions.

When a *pension writ* is issued, none sued thereby in the inns of court shall be discharged, or permitted to come into commons, till all duties be paid.

Hence a *pension order*, in the same inn, is a peremptory order against such of the society as are in arrear for *pensions*, and other duties.

PENSIONARY, or PENSIONER, a person who has a *pension*, appointment, or yearly sum, payable during life, by way of acknowlegement; charged on the estate of a prince, company, particular person, or the like.

In the Romish countries it is frequent to have *pensions* on benefices: these were anciently granted with a great deal of ease, under pretence of infirmities, poverty, &c. But since the twelfth century, these pretences were carried so far, that the incumbents, or titularies of benefices, were little more than farmers.

This obliged the spiritual powers to fix the causes, and the quantities, of *pensions*. *Pensions* are now only creatable by the pope, and are never to exceed one third of the revenue; two-thirds being still to remain to the incumbent.

PENSIONARY is also the appellation of the first minister of the states of the province of Holland.

The *pensionary* is chairman in assemblies of the states of that province; he proposes the matters to be consulted on, collects the votes, forms and pronounces the resolutions of the states; he also opens letters, confers with foreign ministers, &c.

He is charged with inspecting the finances, preserving the rights of the province, maintaining the authority of the states, and seeing to the observation of the laws, &c. for the good of the state. He assists in the college of deputy-counsellors of the province, who represent the sovereignty in the absence of the states; and he is perpetual deputy of the states-general of the United Provinces. His commission is only given for five years; after which it is deliberated whether or no it shall be renewed. Indeed there is no instance of its having been revoked. Death only puts a period to the functions of this important minister. Formerly he was called the *advocate of the province*: the title *pensionary* was only given at the time Barnevelt had the office. Grotius calls him in Latin *adjutor jurisperitus*; Meruis, *advocatus generalis*; and Matthæus, professor at Leyden, *consiliarius pensionarius*, which is the quality the states give him in their instruments.

PENSIONARY is also the first minister of the regency of each city, in the province of Holland.

His office is, to give his advice in matters relating to the government, either of the city in particular, or of the state in general; and in assemblies of the states of the province he is speaker in behalf of his city.

Yet the function of these *pensionaries* is not alike everywhere: in some cities they only give their advice; and are never found in assemblies of the magistrates, except when expressly called thither: in others they attend constantly; and in others they even make the propositions on the part of the burgher-masters, draw up their conclusions, &c. They are called *pensionaries*, because they receive an appointment or *pension*.

PENSIONERS, *gentlemen*, a band of gentlemen, whose business it is to guard the king's person in his own house; and who for that end wait in the presence-chamber.

They were first set on foot by king Henry VII. the number is forty; and each is obliged to keep three double horses, and a servant, who is to be armed; so that they properly make a troop of guards, and have accordingly been mustered by their own officers; but this part of duty, to which they are sworn, the king usually dispenses with.

Their officers are a captain, whose salary is 1000*l.* a year, lieutenant, with 500*l.* a year, standard-bearer, with 312*l.* a year, and clerk of the cheque, whose annual appointment is 120*l.* Their ordinary arms are gilt pole-axes, with which they attend the king to and from the chapel-royal; receiving him in the presence-chamber, or coming out of his private lodging; as also at all great solemnities. Their *pension* 100*l. per annum*.

To this band belong also a pay-master, harbinger, are-keeper, and messenger.

PENSIONS *of churches*, are certain sums of money paid to clergymen in lieu of tithes; and some churches have settled on them annuities, *pensions*, &c. payable by other churches: which *pensions* are due by virtue of some decree made by an ecclesiastical judge upon a controversy for tithes, by which the tithes have been decreed to be enjoyed by one, and a *pension* instead thereof to be paid to another; or they have arisen by virtue of a deed made by the consent of the parson, patron, and ordinary; and if such *pension* hath been usually paid for twenty years,

then it may be claimed by prescription, and be recovered in the spiritual courts; or a parson may prosecute his suit for a *penſion* by prescription, either in that court, or at common law, by a writ of annuity; but if he takes his remedy at law, he ſhall never afterwards ſue in the ſpiritual court. If the preſcription be denied, that muſt be tried by the common law. F. N. B. 51. Hard. 230. Ventr. 120.

PENSTOCK. See PEN.

PENTACEROS, in *Natural Hiſtory*, a name given by Linnæus, and ſome other authors, to a kind of *ſtella marina*, or *ſea ſtar-fiſh*, compoſed of five principal rays, with ſeveral tranſverſe hairy or downy proceſſes.

PENTACHORD, compounded of πεντε, *five*, and χορδη, *ſtring*, an ancient muſical inſtrument with five ſtrings.

The invention of the *penta-chord* is referred to the Scythians; the ſtrings were of bullocks leather, and they were ſtruck with a plectrum made of goats horn.

PENTACROSTIC, a ſet or ſeries of verſes ſo diſpoſed, as that there are always found five ACROSTICS of the ſame name, in five diviſions of each verſe.

PENTACTINODOS, in *Natural Hiſtory*, a name given by ſome authors to thoſe ſpecies of ſtar-fiſh which are compoſed of a body divided into five rays.

PENTADACTYLON, *five fingers*, in *Botany*, a name given by ſome authors to the *ricinus*, or *palma Chriſti*, from the figure of its leaf.

PENTADACTYLOS *piſcis*, the *five-fingered fiſh*, in *Ichthyology*, the name of a fiſh common in all the ſeas about the Eaſt Indies, and called by the Dutch there *vyf vinger viſch*.

It has this name from five black ſtreaks which it has on each ſide, reſembling the prints of five fingers. It grows to about a foot and a half long; its head ſmall in proportion to its body; its mouth is long, and its fins large, and reaching almoſt to its tail; its general colour is very bright and elegant, a yellow with an admixture of purple, and of a ſilvery gloſs; it has no ſcales, and is a dry but not ill-taſted fiſh.

PENTADACTYLOS-ASTER, in *Natural Hiſtory*, a name given by Linnæus, and ſome other authors, to a ſpecies of *ſtar-fiſh*, compoſed of a ſmall body, and five principal rays, which have each ſeveral proceſſes coming from them, covered with down.

PENTAEDROSTYLIA, in *Natural Hiſtory*, the name of a genus of ſpars.

The word is derived from the Greek πεντε, *five*, εδρα, *ſides*, and στυλος, a *column*.

The bodies of this genus are ſpars, in form of pentangular columns, terminated by pentangular pyramids at one end, and irregularly affixed at the other to ſome ſolid body.

Of this genus there are three known ſpecies.

PENTAGON, from πεντε, *quinque*, *five*, and γωνια, *angle*, in *Geometry*, a figure of five ſides, and five angles.

If the five ſides are equal, the angles are ſo too; and the figure is called a *regular pentagon*, as *fig.* 69. *Tab.* III. *Geometry*. Moſt citadels are regular *pentagons*.

The moſt conſiderable property of a *pentagon* is, that one of its ſides, e. g. DE, is equal in power to the ſides of a hexagon and a decagon inſcribed in the ſame circle ABCDE; that is, the ſquare of the ſide DE is equal to the ſum of the ſquares of the ſides D*d* and D*b*.

Pappus has alſo demonſtrated, that twelve regular *pentagons* contain more than twenty triangles inſcribed in the ſame circle, lib. v. prob. 45.

The dodecahedron, which is the fourth regular body, conſiſts of twelve *pentagons*.

PENTAGON, *projection, or perſpective of a*. See PERSPECTIVE.

PENTAGON-ASTER, in *Natural Hiſtory*, a name given by Linnæus, and other authors, to a kind of *ſtella marina*, or *ſtar-fiſh*, compoſed of five rays, with a number of tranſverſe proceſſes riſing from them, covered with a hairyneſs.

It is one of the general claſſes of the *ſtellæ crinitæ*, ſo called from this hairyneſs.

PENTAGONOTHECA, in *Botany*, the name given by Vaillant to the plant called by Linnæus, Plumier, Houſton, and others, PIPEWORT.

PENTAGRAPH, an inſtrument whereby deſigns, prints, &c. of any kind, may be copied in any proportion, without a perſon's being ſkilled in drawing.

The inſtrument is otherwiſe called a *parallelogram*.

The common *pentagraph* (repreſented *Tab.* II. *Miſcel. fig.* 27.) conſiſts of four braſs or wooden rulers, two of them from fifteen to eighteen inches long, the other two half that length. At the ends, and in the middle, of the longer rulers, as alſo at the ends of the ſhorter, are holes, upon the exact fixing whereof the perfection of the inſtrument chiefly depends. Thoſe in the middle of the long rulers are to be at the ſame diſtance from thoſe at the end of the long ones, and thoſe of the ſhort ones; ſo that, when put together, they may always make a parallelogram.

The inſtrument is fitted together for uſe, by ſeveral little pieces, particularly a little pillar, N° 1. having at one end a ſcrew and nut, whereby the two long rulers are joined; and at the other a little knot for the inſtrument to ſlide on. The piece, N° 2. is a rivet with a ſcrew and nut, whereby each ſhort ruler is faſtened to the middle of each long one. The piece, N° 3. is a pillar, one end whereof, being hollowed into a ſcrew, has a nut fitted to it. At the other end is a worm to ſcrew into the table; when the inſtrument is to be uſed, it joins the ends of the two ſhort rulers. The piece, N° 4. is a pen, portcrayon, or pencil, ſcrewed into a little pillar. Laſtly, the piece, N° 5. is a braſs point, moderately blunt, ſcrewed likewiſe into a little pillar.

Uſe of the PENTAGRAPH, or *parallelogram*. 1. To copy a deſign in the ſame ſcale or bigneſs as the original: ſcrew the worm, N° 3. into the table; lay a paper under the pencil, N° 4. and the deſign under the point, N° 5. This done, conducting the point over the ſeveral lines and parts of the deſign, the pencil will draw or repeat the ſame on the paper.

2. If the deſign be to be reduced—e. gr. into half the ſpace, the worm muſt be placed at the end of the long ruler, N° 4. and the paper and pencil in the middle. In this ſituation conduct the braſs point over the ſeveral lines of the deſign, as before; and the pencil at the ſame time will draw the copy in the proportion required; the pencil here only moving half the length that the point moves.

Hence, on the contrary, if the deſign be to be enlarged by one half, the braſs point, with the deſign, muſt be placed in the middle, at N° 5. the pencil and paper at the end of the long rules, and the worm at the other.

3. To enlarge or reduce in other proportions, there are holes drilled at equal diſtances on each ruler; viz. all along the ſhort ones, and half way of the long ones, in order for placing the braſs point, pencil, and worm, in a right line thereto. If the piece carrying the point be put in the third hole, the two other pieces muſt be put in its third hole.

If then, the point and deſign be placed at any hole of the great rulers, and the pencil with the paper at any hole of the ſhort ruler, which forms the ſame theorem, the copy will be leſs than half the original. On the contrary, if it be placed at one of the holes of that long ruler, which is parallel to the long ruler, the copy will be greater than half the original.

The conſtruction of this inſtrument requires a degree of accuracy, which moſt of our inſtrument-makers are ſtrangers to; for which reaſon there are very few of the inſtruments that ſucceed. Few will do any thing tolerably but ſtreight lines; and many of them not even thoſe. In order to prove that the figure deſcribed by a *pentagraph* is ſimilar to the given figure; let C, *fig.* 28. be the fixed centre of motion; P the pencil for tracing the given figure PP, and *p* the pencil which traces the other figure *p p*; *p*, &c. muſt be ſo adjuſted, that *p*, C and B, may lie in one ſtreight line; then, ſince B *p* : A *p* :: BP : AC, whatever be the ſituation of the *pentagraph*, the angles PCP and *p*C*p*, are vertical, and, therefore, PC*p* will in every poſition of the inſtrument be a right line; but PC : *p*C :: BA : A*p*, in each of the two poſitions in the figure, and conſequently the triangles PCP, *p*C*p*, are ſimilar; and PP : *p p* :: PC : *p*C :: BA : A*p*, or in a given ratio. Hence it appears, that by moving the pencil *p*, A*p* may be equal to BA, or leſs in any proportion; and conſequently *p p* may be equal to PP, or leſs, in the ſame proportion.

PENTAMETER, derived from πεντε, and μετρον, *meaſure*, in *Poetry*, a kind of verſe conſiſting of five feet or metres.

The two firſt feet of a *pentameter* may be either dactyls or ſpondees; the third muſt be always a ſpondee; and the two laſt anapeſts.

It is uſually joined to hexameters, in elegies, epiſtles, epigrams, and other little pieces. There is no work of conſtant *pentameters* alone.

PENTANDRIA, formed of πεντε, *five*, and ανηρ, *male*, in *Botany*, the fifth claſs of plants, which have hermaphrodite flowers, with five ſtamina or male parts in each. See *Tab.* I. of *Botany*, *Claſſ.* 5. and *Tab.* III. *Claſſ.* 5.

Of this claſs of plants, which comprehend ſix orders, diſtinguiſhed by the number of ſtyles, are the primroſe, willow herb, honeyſuckle, &c.

PENTANGLE, in *Geometry*, a figure with five angles.

PENTAPETALOUS *plants*, are ſuch whoſe flowers conſiſt of five leaves.

PENTAPETES, in *Botany*, a genus of the *monadelphia decandria* claſs. Its characters are theſe: the flower has a double ſupplement, the outer being ſmall, and compoſed

posed of three leaves; the inner cut into five parts, which are reflexed; it has five oblong petals, which spread open, and fifteen narrow stamina joined in a tube at their base, with long coloured summits that are erect and barren; between each of these are three stamina, terminated by oblong, erect summits; it has a roundish germen, with a cylindrical style the length of the stamina, crowned by a thick stigma; the germen becomes an oval, ligneous capsule, with five cells, filled with oblong seeds. Miller mentions one species, a native of India. Linnæus enumerates three species.

PENTAPHARMACUM, a medicine consisting of five ingredients: it has also been used in the same sense to all menses. Adrian the emperor was, as we are informed, particularly fond of a dish of five ingredients, called by this name. The ingredients were the udder of a sow, ham, peacock, brawn, and a fore of paste.

PENTAPHYLLOIDES, in *Botany*. See CINQUEFOIL.

PENTAPLEURUM, a name given by some botanical writers to the common small plantain, usually called *ribwort* and *sheatage quinquenervia*, from its leaves always having just five ribs running along them.

PENTAPOLIS, *Πεντάπολις*, in *Geography*, &c. a country wherein are five cities.

The most celebrated was the *Pentapolis Cyrenaica*, or *Pentapolis* of Egypt, whose five cities were Berenice, Arsinoe, Ptolemais, Cyrene, and Apollonia.

Among the ancient geographers and historians, we likewise read of the *Pentapolis* of Libya, now called *Mesurata*; the *Pentapolis* of Italy; and the *Pentapolis* of Asia Minor.

PENTAPTEROPHYLLUM, in *Botany*, a name by which Dillenius has called the MYRIOPHYLLUM of other authors, characterised under that name in the Genera Plantarum of Linnæus, p. 459.

PENTAPTOTON, in *Grammar*, a noun which has only five cases.

PENTASTICH, *pentastichon*, in *Poetry*, a stanza, or division of a poem, consisting of five verses.

PENTASTYLE, in *Architecture*, a work wherein are five rows of columns.

Such was the portico begun by the emperor Gallienus, and which was to have been continued from the Flaminian gate to the bridge Milvius, i. e. from the Porto del Popolo, to the Porte Mole.

PENTATEUCH, in the *Sacred Learning*, the five books of Moses at the head of the Old Testament; viz. Genesis, Exodus, Leviticus, Numbers, and Deuteronomy. The word is formed from *πέντε*, which signifies the same; compounded of *πεντ*, *five*, and *τεύχος*, *volume*.

Pere Simon, in his Hist. Crit. du V. Test. produces a great number of passages to prove, that Moses was not wholly the author of the *Pentateuch*, as we now have it. Indeed, those apparent interpolations at the end are sufficient to determine that point; it being absurd to suppose Moses the author of the account of his own death and burial, and of the comparison between him and the succeeding prophets in Israel.

These interpolated passages are usually attributed to Esdras; who, on his return from the Babylonish captivity, is supposed to have published the Old Testament, or at least a part of it, corrected and enlarged.

There are two famous *Pentateuchs*, or editions of the *Pentateuch*, which have a long time disputed the preference, both as to antiquity, and as to character; viz. that of the Jews, called the *Jewish* or *Hebrew Pentateuch*, written in the Chaldean or Assyrian character; and that of the Samaritans, written in the Samaritan or Phœnician character. Each is maintained to be the ancient Hebrew; though the generality of the critics give it in behalf of the latter.

Indeed, as to the point of matter, they are generally pretty conformable to each other; each has all the interpolated passages above mentioned, though the Samaritan has one or two more, which are not in the Hebrew: the first a passage in Deut. xxvii. 4. where an altar is enjoined to be built, and sacrifices to be offered, on mount Ebal, or rather mount Gerizim; which passage was doubtless foisted in to countenance the Samaritan worship, and represent it of equal antiquity with that of the temple of Jerusalem. See SAMARITANS.

But the grand difference is in the letter or character: the Jewish being in the Chaldean or Assyrian character, and the Samaritan in the Phœnician, i. e. the Canaanitish character; this latter seems to have an advantage over the vulgar Jewish *Pentateuch*. Yet Prideaux is of opinion, that the latter is only a transcript from the former out of the Chaldean into the old Hebrew character. One great reason he gives, is, that there are many variations in the Samaritan, manifestly occasioned by mistaking the similar letters in the Hebrew alphabet; which letters having no similitude in the Samaritan character, it is evident the variations must have arisen in transcribing from the vulgar Hebrew into the Samaritan; and not the contrary way.

Add to this, that Simon, Allix, and many other learned men, take the Chaldean or Assyrian character to have been the character always in use among the Jews; and the Samaritan or Canaanitish, or, as it is also called, the *old Hebrew* character, to have never been used by the Jews before the captivity, in any manner, either on books, or on medals.

Hence the *Pentateuch* must have been transcribed into that character; and that, probably, to render it legible to the inhabitants of Samaria, who, upon their introduction of the *Pentateuch*, might probably be versed in no other character.

Usher takes the Samaritan *Pentateuch* to have been compiled by Dositheus, a Samaritan, mentioned by Origen to have adulterated the *Pentateuch*. Dupin supposes it the work of some modern Samaritan, whom he imagines to have compiled it chiefly out of the different copies of the Palestinian and Babylonian Jews, and the Septuagint; because it sometimes agrees with one, and sometimes with another.

The Jews read the whole *Pentateuch* every year; and for this purpose they divide it into paragraphs or sections, which they distinguish into great and small. The great are those which they read in a week, of which there are fifty-four (see PARASCHE); and the small regard particular matters. Each greater section, which is denominated by the word with which it begins, is divided into seven parts, because they are read by so many different persons: the priest begins, afterwards a Levite; and in the choice of the other readers, respect is paid to the rank of the people. After the text of Moses, they read a paragraph of the PARAPHRASE of Onkelos. The books of the prophets are also divided in the same manner.

PENTATHLON, *πενταθλον*, in *Antiquity*, the five exercises performed at the Grecian games, and for which prizes were proposed.

These exercises were wrestling, darting, leaping, running, and quoit-playing. He who bore away the prize in them all, was called *pentathlos*; by the Latins, *quinquertio*; as the five exercises themselves were by those latter people called *quinquertium*.

PENTATONON, in the *Ancient Music*, a concord, by us called the redundant sixth.

It consists of four tones, and a major and minor semitone; whence the name, *pentatonon*, q. d. *five tones*.

PENTAUREA, a name given by some fabulous authors to a stone said to have been first found by Apollonius Tyaneus, and to possess the virtues of all the other stones, and to attract them all to it, as the magnet does iron.

PENTECONTARCHA, among the *Ancients*, the captain or commander of a galley, called PENTECONTEROS.

PENTECONTEROS, *πεντηκόντορος*, a vessel with fifty oars.

PENTECOST, *Πεντηκοστή*, Whitsuntide; a solemn feast of the church, held in commemoration of the descent of the Holy Ghost on the apostles; as described in the Acts. See WHITSUNTIDE.

It has its name from the Greek *πεντηκοστος*, q. d. *quinquagesimus*, *fiftieth*, because held on the fiftieth day after EASTER.

In the ancient church, *Pentecost* finished the Paschal time, or Easter season; wherein, as Tertullian, St. Jerom, &c. observe, Hallelujah was sung every where, the office celebrated standing, no fasting allowed, &c.

The Jews likewise had a feast they called *Pentecost*, or *Quinquagesimus*, solemnized in memory of the Law's being given to Moses, fifty days after their departure out of Egypt.

This was the second of the three grand festivals in the ecclesiastical year, at which all the males were to appear before the Lord at the national altar. It is called by several names in the Old Testament; as the Feast of Weeks, because it was celebrated seven weeks, or a week of weeks, after the Passover, or rather, after the first day of the feast of unleavened bread; the Feast of Harvest, according to Mede and Bochart, because, as the harvest began at the Passover, it ended at *Pentecost*; or, according to others, because at this feast the first fruits of their wheat harvest were brought and offered to God; and the Feast of First Fruits.

PENTECOSTALS, *Pentecostalia*, anciently, were pious oblations made at the feast of *Pentecost*, by the parishioners to their parish-priests; and sometimes by inferior churches or parishes, to the principal or mother-church.

These parish *Pentecostals* were also called *Whitsun-farthings*; and their sum was divided into four parts, of which one went to the priest, one to the poor, one towards the repair of the church, and one to the bishop of the diocese.

These

These are still paid in some few dioceses; being now only a charge upon particular churches, where by custom they have been paid.

PENTELASMIS, in the *History of Shell-fish*, the name of the *concha* ANATIFERA of some writers.

The *pentelasmis* is a genus of animals, composed of a shelly body, affixed to a fleshy and soft pedicle; the body is composed of five valves, and the pedicle is sometimes short, and sometimes long. The animal itself belongs to the TRITONS.

PENTELICUM *marmor*, in the *Works of the Ancients*, a name given to a very beautiful and goodly species of white marble, of which many of the columns and statues of larger size of the ancients were made: the Parian marble, from certain cracks and fissures in the strata, seldom affording blocks of more than five feet in length.

PENTESYRINGUS, in *Antiquity*, a sort of pillory, with five holes; wherein were fastened the legs, arms, and heads, of criminals, to prevent their stirring.

PENTEXOCHE, a name given by authors to a species of echinites, resembling the ripe fruit of a medlar, and thence called also *mespilum lapis*.

PENTHEMIMERIS, πενθημιμερὴς, compounded of πέντε, *five*, μέρος, *half*, and μέρος, *part*, in the Greek and Latin *Poetry*, part of a verse, consisting of two feet, and one long syllable.

PENTHORUM, in *Botany*, a genus of plants of the *decandria pentagynia* class, the characters of which are these: the cup is very small and permanent; it is composed of one leaf divided into five segments at the edges; there is no flower; the stamina are ten setaceous filaments of double the length of the cup; these are permanent; the antheræ are roundish, and fall off very quickly; the germen of the pistil is divided into five parts, and terminates in five styles, which are conic, erect, and of the length of the stamina; the stigmata are obtuse; the fruit is a capsule divided into five parts, and containing five cells; the seeds are numerous, small, and compressed. There is only one species.

PENTODRYON, in *Botany*, a name given first by the Greek writers, and after that by the Romans, to a kind of *hyoscyamus* or *nightshade*, which caused madness in those who eat of it. This was called by others *maniacum hyoscyamus*, and by some simply *manicum*.

PENTOPHTHALMOS, in *Ichthyology*, the name of an East Indian fish, approaching to the European *sparus*, or *bream-fish*, but larger, and called by the Dutch there *ogt-spys*. It has these names from five round spots in the tail-fin, resembling five eyes; it is of a yellowish colour, and is covered with a smooth skin, having no scales; its body is thick, its head small, its beak long; it has two red fins, and its tail is bluish; it is an inhabitant of the fresh waters, and is a very well-tasted fish.

PENULA. See PENULA.

PENULTIMA, or PENULTIMATE, formed from *pene*, and *ultimus*, *almost last*, in *Grammar*, denotes the syllable, or foot, immediately before the last.

Hence *antepenultimate* is that before the *penultimate*, or the last but two.

PENULTIMATE, in *Music*. M. Brossard will have it the same with what the Greeks called *paranete*; though others will not allow the *paranete* to be the *penultimate* chord, but the next to it.

PENULTIMATE *of the separate*, *paranete diezeugmenon*, is a name the ancients gave to one of the chords of their lyre or system, corresponding to the *d*, *la*, *re*, of the third octave of the modern system.

PENULTIMATE *of the acute*, *paranete hyperbolon*, a chord of the ancient system, answering to the *g*, *re*, *sol*, of the third octave of the modern system.

PENUMBRA, in *Astronomy*, a faint or partial shade, observed between the perfect shadow and the full light in an eclipse.

The *penumbra* arises from the magnitude of the sun's body: were he only a luminous point, the shadow would be all perfect; but by reason of the diameter of the sun it happens that a place which is not illuminated by the whole body of the sun, does yet receive rays from a part thereof.

Thus suppose S the sun (*Tab. Astron. fig.* 43.) and T the moon, and the shadow of the latter to be projected on a plane, as G H. The true proper shadow of T, viz. G H, will be encompassed with an imperfect shadow, or *penumbra*, H L and G E, each portion whereof is illuminated by an entire hemisphere of the sun.

The degree of light or shadow of the *penumbra* will be different in different parts, as those parts lie open to the rays of a greater or lesser part of the sun's body; thus from L to H, and from E to G, the light continually diminishes; and in the confines of G and H, the *penumbra* becomes loft and confounded with the total shade; as near E and L, it is confounded with the total light.

A *penumbra* muft be found in all eclipfes, whether of the fun, the moon, or the other planets, primary or fecondary; but it is moft conſiderable with us in eclipſes of the fun; as is the caſe here referred to.

In eclipſes of the moon, the earth is encompaſſed indeed with a *penumbra*; but it is only ſenſible to us on the earth near the total ſhadow: an obſerver placed on a plane, whereon the ſhadow falls, might obſerve the whole *penumbra*, as in eclipſes of the ſun. Thus an eye placed at I or F, would only ſee the ſemidiameter of the ſun; the reſt being hid behind the moon. Going from I towards H, more and more of the ſun is hid, till it be loſt in the ſhadow itſelf, &c.

Hence we have eclipſes of the ſun when the ſhadow never touches the earth, provided the *penumbra* do but reach it; and hence there is a difference obſerved in eclipſes of the ſun, as the ſhadow itſelf, or a greater or leſs degree of the *penumbra*, paſſes over a place. But eclipſes of the moon appear the ſame in all places where they are viſible.

When the ſhadow itſelf falls on the earth, the eclipſe is ſaid to be total or central; when only the *penumbra* falls on it, the eclipſe is ſaid to be partial.

The *penumbra* extends infinitely in length, inaſmuch as to each point of the diameter of the ſun, there anſwers a ſpace infinite in length, into which no rays enter from that point, though there do from others. Two rays drawn from the two extremities of the earth's diameter, and which proceed ſtill diverging, form the two edges of the *penumbra*; which, of conſequence, is continually growing in width, and is infinite alſo in this ſenſe. All that infinite ſpace is the *penumbra*; except the triangle of the ſhadow included in it.

The figure of this ſpace comprehending the ſhadow, is a trapezium, one of whoſe ſides is the diameter of the earth; the oppoſite ſide parallel thereto is an infinite line, i. e. the width of the *penumbra* projected to infinity; and the two other ſides are two rays drawn from the two extremities of the diameter of the ſun, through thoſe of the diameter of the earth, and which, prolonged back beyond the ſun, will interſect in a certain point, making an angle equal to the apparent diameter of the ſun; which angle may be called the *angle of the penumbra*.

Now the *penumbra* will be the greater, as this angle, or which is the ſame thing, as the ſtar is greater, the planet remaining the ſame; and if the diameter of the planet be increaſed, the ſtar remaining the ſame, it will be the ſame as if the diameter ſtill receded from the angle of the *penumbra*.

In order to determine how much of the ſurface of the earth can be involved in the *penumbra*, let us ſuppoſe the apparent ſemidiameter of the ſun to be the greateſt, or about 16′ 32″, which is when the earth is in her perihelion. Let A B D (*Tab. Aſtronom. fig.* 44.) be the earth, I, the moon, and A M B half the angle of the cone, which is equal to 16′ 32″; whence we ſhall find its height I M = 584 ſemidiameters of the earth (ſee SHADOW). Let the moon be in her apogee, and therefore, at her greateſt diſtance from the earth, which is 64 ſemidiameters of the earth, and T M = T I + I M = 122½ ſemidiameters. But T B : T M :: ſine of T M B : ſine of M B N or M B T: and T B : T M :: 1 : 122½, and the angle T M B = 16′ 23″, therefore the angle M B N = 35° 42′ = T M B + M T B. Conſequently M B N — T M B = (35° 42′ — 16′ 23″ =) M T B = 35° 25′, which is the meaſure of the arc A D; whoſe double 70° 51′ is equal to the arc C A D, or about 4900 Engliſh miles. See ECLIPSE.

M. de la Hire examines the different degrees of the *penumbra*, and repreſents them geometrically by the ordinates of a curve, which ſhall be among themſelves, as the ſeveral parts of the ſun's diſc, wherewith a body placed in the *penumbra* is enlightened.

PENY. See PENNY.

PEONY, in *Botany*. See PIONY.

PEP and PEPIA. See PIP.

PEPASMUS, πέπασμος, in *Medicine*, the digeſting and ripening of morbid humours.

PEPASTIC, or PEPTIC, πεπαστικὸς, or πεπτικὸς, formed from πέπτειν, *to digeſt or ripen*, in *Medicine*, a kind of medicament of the conſiſtence of a plaiſter, proper to bring vitious and corrupt humours to a head, and diſpoſe them for ſuppuration.

Butter, roots of mallows, of fleurs-de-lis, onions, and leaves of oxylapathum, are eſteemed good *pepaſtica*, or maturatives.

The word is alſo uſed for ſuch medicines as promote the digeſtion of food in the ſtomach.

PEPITA, in the *Materia Medica*, a name given by ſome authors to the *nux ſancti Ignatii*, or *St. Ignatius's nut*.

PEPLION, or PEPLOS, names given by the antients to medicines which they uſed as brisk cathartics to purge off the bile and other humours.

PEPLIS, in *Botany*. See *Water* PURSLANE.

PEPLIUM, in *Botany*, a name given by the ancient Greek writers to a ſhrub which had pinnated leaves and papilionaceous flowers. It is tranſlated by many *ſena*; but this does not appear certainly to be right; the ſeveral ſpecies of *colutea* agree as well with this deſcription as the *ſena*, and they have indeed been called *ſena* by many; probably it was one of theſe.

PEPLUS, πεπλος, among the ancients, a kind of garment worn by women.

The *peplus* was a long robe that reached to the feet, without any ſleeves, and ſo exceeding fine, that the ſhape of the body could eaſily be diſcovered through it.

The *peplus* of Minerva is very famous among ancient mythologiſts. The Athenians uſed a great deal of ceremony in making the *peplus*, and dreſſing the ſtatue of this goddeſs with it.

PEPLUS, in *Botany*, a name given by ſome authors to the ſmaller round-leaved ſpecies of *tithymal*, or SPURGE, as they call the narrow-leaved ones *eſula*.

PEPO, in *Botany*. See PUMPKIN.

PEPPER, or *Lenard's Tail*, in *Botany*, *piper*, a genus of the *diandria trigynia* claſs. Its characters are, that the flowers are cloſely faſtened to a ſingle ſtalk, and have no complete cheath; theſe have no petals nor ſtamina, but have two ſummits oppoſite to the robe of the germen, which are roundiſh; they have a large oval germen, but no ſtyle, crowned by a prickly triple ſtigma; the germen afterwards becomes a roundiſh berry, with one cell, containing one globular ſeed. Miller enumerates fourteen, Linnæus twenty ſpecies. From a ſpecies of this genus is obtained the black *pepper*, which is an aromatic fruit of a hot dry quality, chiefly uſed in the ſeaſoning of meats.

It is the product of a ſhrub, growing in ſeveral parts of the Eaſt Indies, chiefly Java, Sumatra, Malacca, and the coaſts of Malabar. The plant is very weak, and of the reptile kind; and for that reaſon uſually planted at the foot of the larger trees, as the areca, cocoa, &c.

Pepper grows in bunches or cluſters, at firſt green; as the grains ripen, they grow reddiſh; and, at laſt, after being expoſed a while to the ſun, and, probably, gathered before perfect maturity, they become black, in the condition we ſee them.

The fruit is gathered in November. It muſt be choſen large, full, not wrinkled, without duſt, with a good many white grains in it; and care muſt be taken the largeſt borries have not been picked out, as is often done, to make white *pepper*.

PEPPER, *white*, *piper album*, is the fruit of the ſame plant with the black, and is prepared from it by moiſtening it with the ſea-water, and then expoſing it in the ſun, and caſting away the outer bark, which, abandoning the grains, leaves them white.

Indeed M. Deſlon, a late traveller, ſays, they ſtrip off the ſkin, by beating it before it be quite dry; or by ſoaking it in water after it has dried, and then beating it.

Many authors, and among the reſt Pomet, will have the *white pepper* to be natural, and the fruit of a different plant from the black; but M. Deſlon, who expreſly declares the contrary from his own long experience, ſeems to put the matter paſt doubt.

White pepper muſt be choſen after the ſame manner as black; with this further care that it hath not been dyed white.

Pepper that is ſold ground, is very apt to be ſophiſticated; the black with burnt cruſt of bread, &c. the white with beaten rice.

Of theſe pungent ſpices the black ſort is the hotteſt and ſtrongeſt, and moſt commonly uſed for medicinal, as well as culinary purpoſes. *Pepper*, infuſed in water, impregnates the menſtruum pretty ſtrongly with its flavour, but weakly with its taſte: the eſſential oil, which riſes to the ſurface of the water in boiling it, is thin, light, and limpid; in ſmell, ſtrong and agreeable; and in taſte, mild. The quantity of extracts from both kinds of *pepper* is nearly the ſame; that by rectified ſpirit amounting to about one-eighth, and the watery to near one half their weight. But thoſe of the white are weaker than the other ſort.

PEPPER, *long*, *piper longum*, is thus denominated from its form, which is cylindrical and about an inch and a half in length; it conſiſts of an aſſemblage of grains, or ſeeds, joined cloſe to one another, of a browniſh colour, bordering without on red, and within on black; and grows by a long pedicle to a plant, like that of the black *pepper*, and of the ſame genus, but lower, and its leaves ſmaller and greener. Its taſte reſembles that of the former, but it is hotter and more pungent; and its ſpirituous extract is proportionably more fiery: in its pharmaceutic properties, it entirely agrees with the former.

There are three kinds of this *pepper*, that of the Eaſt Indies, that of America, and that of Ethiopia, called alſo grain of Zelim; though the firſt alone is the proper *long pepper*, the reſt reſembling it but little.

It muſt be choſen new, large, heavy, well filled, hard to break, and without duſt or mixture: it chief uſe is in medicine, where it enters ſeveral Galenical compoſitions; among the reſt Venice treacle.

PEPPER, *Barbary*, *bell*, *bird*, and *bonnet*. See CAPSICUM.

PEPPER, *Guinea*, *piper Indicum*, obtained from a ſpecies of the CAPSICUM, is a reddiſh pod, of a coral colour, much eſteemed by the Americans, from among whom it is brought, and by them called *chile*, and by the French, *garden coral*.

It is a native of the Eaſt and Weſt Indies, and raiſed in ſome of our gardens.

It is now cultivated pretty commonly in France, eſpecially in Languedoc, where it is uſed in making vinegar, and is likewiſe comfited with ſugar. It muſt be choſen new, in large pods, dry, entire, and red.

In taſte it is extremely pungent and acrimonious; it gives out its pungency to rectified ſpirit, together with a pale yelloviſh red tincture. It is ſometimes given, in ſmall quantities, as one of the higheſt ſtimulants in cold phlegmatic temperaments, in ſome paralytic caſes, to relaxations and inſenſibility of the ſtomach, and for promoting the efficacy of aloetic medicines, and the deobſtruent gums in uterine diſorders.

It is uſed principally at table: a ſpecies of it, called in the Weſt Indies *bird-pepper*, is the baſis of the powder brought from thence under the name of *Cayenne pepper*. See CAPSICUM.

There are four kinds of this; the firſt called by the Americans *cilliehotes*; the ſecond, very ſmall, *chilterpin*; both of a very pungent taſte; the third, *tonalchiles*, moderately hot, and eaten by the natives like other fruit with bread; the fourth, *chilpelagua*, moderately pungent, ſometimes uſed by the Spaniards in the preparation of chocolate; there is alſo a fifth kind, called *agy*, growing in Peru.

PEPPER, *Jamaica*, called by the Dutch *amomi*, by the Spaniards *pimienta de Jamaica*, is the fruit of a tree, the *myrtus foliis alternis* of Linnæus, growing plentifully in Jamaica, and other American iſlands.

It is a real aromatic, and may ſupply the defect of cloves, nutmeg, and cinnamon; whence it is called alſo by the Engliſh, *all-ſpice*. The French call it the *round clove*, from its round ſhape, and its taſte reſembling that ſpice. See PIMENTO.

PEPPER, *Ciapa*, *pimienta de Ciapa*, a name given by the Spaniards to a ſort of ſpice which they diſcovered in Ciapa, a province of Guatimala, in New Spain, and of which they were at firſt very fond, both in food and medicine.

In medicine it is a very good cephalic and ſtomachic. It is recommended very ſtrongly alſo by ſome of the Spaniſh writers, as a cure for the epilepſy and gutta ſerena; but thoſe who tried it in theſe caſes do not confirm ſuch accounts.

The deſcriptions we have of it are, that it has the taſte of cloves, *pepper*, cinnamon, and ginger, all blended together; and Redi is of opinion, that it is no other than our PIMENTO, or Jamaica *pepper*.

PEPPER, *Indian*. See *Guinea* PEPPER and CAPSICUM.

PEPPER, *poor-man's*, a name ſometimes given to the *lepidium*. See DITTANDER.

PEPPER, *wall*, a name ſometime given to a ſpecies of SEDUM, or *leſſer houſe-leek*.

PEPPER, *water*, a ſpecies of *polygonum*, or KNOT-*graſs*, in the Linnæan ſyſtem. Miller and others make it a ſpecies of the *perſicaria*, or ARSMART.

PEPPER-*graſs*. See PILULARIA.

PEPPER-*mint*, the name of a ſpecies of MINT.

PEPPER-*wort*, a name by which ſome call the *lepidium*, or DITTANDER.

PEPPER-*bird*, the Engliſh name of the *rhamphaſtos*, with a yellow rump, otherwiſe called TOUCAN.

PEPPER-*muſhroom*, in *Botany*, a name given by Dr. Liſter to a new ſpecies of fungus, diſcovered by him in the woods of Yorkſhire, whoſe juice is acrid and hot as *pepper*. This is ſomewhat larger than the common eſculent muſhroom, but of the ſame ſhape with that, having a round head and open gills underneath. The head is very fleſhy, and the pedicle alſo is ſolid, not hollow, as in moſt other of the large funguſes: any part of this muſhroom being cut or broken, it bleeds very freely a white milky juice, like that of the tithymals. This juice taſtes like *pepper*, only that it is much *hotter*. It is not viſcous or clammy to the touch, and the air does not much diſcolour it; nor does it render the blade of the knife, with which it is cut, black, as moſt other vegetable juices do. When let out of the plant it very ſoon con-

concretes into a firm and dry mass, making a sort of cake; and when thus dried into a solid substance, it retains its white colour and pungent taste. It is very remarkable, that this mushroom, though so hot to our tongues as not to be endured, yet is so well suited to the palates and nature of certain insects, that they can not only feed on it, but live comfortably in the midst of it. The yellow naked fusil feeds greedily on the plant while growing, and the stalks of it at such times as the juice is sharpest of all, that is, while it is growing to the full size, are full of the maggots and worms hatched from the eggs of flies, deposited there for a nidus and food for them in that state. The juice has a great affinity with euphorbium, and may be brought into medicinal use, perhaps, to very good purpose.

John Bauhine describes a mushroom much resembling this, but smaller and less fleshy; and the Prussians and Polanders have a sort of great mushroom, which they call GROGRISHYE, which agrees with this in many particulars; but it is larger and thicker. Phil. Trans. N° 69.

PEPPER-*water*, a liquor prepared by the curious for examination by the *microscope*, as always affording a great number of small animals.

The method of preparing it is this: put common black *pepper*, grossly powdered, into an open vessel, so as to cover the bottom of it half an inch thick, and put to it rain or river water, till it covers it an inch, shake or stir the whole well together, at first mixing, but never stirring it afterwards: let the vessel be exposed to the air, uncovered; and in a few days there will be seen a pellicle or thin skin swimming on the surface of the liquor, appearing of several colours.

This is a congeries of multitudes of small animals; and being examined by the microscope, will be seen all in motion: the animals, at first sight, are so small as not to be distinguishable, unless to the greatest magnifiers; but they grow daily till they arrive at their full size. Their numbers are also continually increasing, till the whole surface of the liquor is full of them, to a considerable depth. When disturbed they will sometimes all dart down to the bottom, but they soon after come up to the surface again. The skin appears soonest in warm weather, and the animals grow the quickest; but in the severest cold it will succeed, unless the water freezes.—Baker's Microscope, p. 71.

About the quantity of a pin's head of this scum, taken up on the nib of a new pen, or the tip of a hair-pencil, is to be laid on a plate of clear glass; and if applied first to the third magnifier, then to a second, and finally to the first, will shew the different animalcules it contains, of several kinds and shapes as well as sizes. Phil. Trans. N° 284.

The animalcules discoverable in this liquor, are principally of six kinds. 1. The largest kind of all is in length about the diameter of a hair, and of scarce a fourth part of that measure in breadth; they are very thin and transparent, but their back is darker than their belly; they turn about very frequently and nimbly in the water; their sides are fringed with a great number of minute feet, which are seen principally at the two ends; and at one end there are also some bristles longer than the feet, which make a sort of tail. They are very nimble, and walk as well as swim, and will climb up a hair, if put in among them.

2. There is a smaller sort, whose length is about a third of a hair's breadth; but their tail is five or six times as long as their body. This they either carry strait, or in a spiral form; and at the other end they thrust out a sort of bearded tongue: these make a constant current of water toward them.

3. There is a smaller sort than these, which are sometimes seen of an oval figure, and sometimes long and flat like a flounder: these also have feet, which are plainly seen when the water is evaporating.

A fourth kind appear like slender worms, fifty times as long as broad: their thickness is not above the hundredth part of a hair's breadth; and they move with equal ease either forward or backward. There are a fifth sort extremely minute and round; and a sixth kind which are longer than these, but not larger; and probably there may be yet many kinds not discovered. These small animals are easily destroyed; a little dissolved salt or sugar, or spirit of vitriol, or even spittle, will kill them; and in the drying away of the waters many of them burst. Phil. Trans. N° 303.

PEPSIS, πεψις, which signifies *boiling*, in *Medicine*, the COCTION or DIGESTION of foods or humours in the body.

PEPTIC, in *Medicine*. See PEPASTIC.

PEPUZIANS, a sect of ancient heretics, otherwise called PHRYGIANS, or CATAPHRYGIANS.

They had their name *Pepuzians*, from a pretence that Jesus Christ appeared to one of their prophetesses in the city of Pepuza in Phrygia, which was their holy city.—See QUINTILIANS.

PER *accidens*. See ACCIDENS.

PER ACUTUM *mensuram*. See MENSURUM.

PER ÆQUATORES, among the Romans, officers appointed to regulate the *census* according to every man's circumstances, by easing those that were overcharged, and raising the taxation if too low.

PERAMBULATION *of the forest*, the surveying, or walking about a forest, or the limits of it, by justices or other officers thereto appointed, to set down the meres and bounds thereof, and what is within the forest, and what without.

PERAMBULATION *of parishes* is annually performed in order to preserve those bounds of parishes which have been long settled by custom; and because these *perambulations* were performed in the rogation week, the rogation days were anciently called *gang-days*, from the Saxon *gan*, or *gangen*, *to go*.

In the *perambulation* of a parish, no refreshments can be claimed by the parishioners, as due of right from any houses or lands in virtue of custom.

These *perambulations* were, in the times of popery, accompanied with great abuses, viz. with feastings and superstition; being performed in the nature of processions, with banners, hand-bells, lights, staying at crosses, and the like; and, therefore, when processions were forbidden, in the reign of queen Elizabeth, it was required, that, for the retaining of the *perambulation* of the circuits of parishes, the people should, once in the year, at the usual time, with the curate and the substantial men of the parish, walk about the parishes, and at their return to church make their common prayers, &c.

PERAMBULATIONE *faciendâ* is a writ commanding the sheriff to make *perambulation*, and set down the bounds of two or more manors, whose limits are not so well known.

The writ *de perambulatione faciendâ* is only issued where the lords of both manors agree to have such perambulation. If one of them refuse, the other must seek his remedy by a writ *de* RATIONABILIBUS *divisis*.

PERAMBULATOR, in *Surveying*, an instrument for the measuring of distances; called also PEDOMETER, *way-wiser*, and *surveying wheel*.

Its advantages are its handiness and expedition: its contrivance is such, that it may be fitted to the wheel of a coach; in which state it performs its office, and measures the road without any trouble at all.

There is some difference in its make: that now most usual, and most convenient, is as follows.

PERAMBULATOR *or way-wiser, construction of the*. The *perambulator* (represented *Tab.* II. *Survey. fig.* 33.) consists of a wheel two feet seven inches and a half in diameter; consequently half a pole, or eight feet and three inches in circumference. On one end of the axis is a nut, three quarters of an inch in diameter, divided into eight teeth, which, upon moving the wheel round, fall into the eight teeth of another nut *c*, fixed on one end of an iron rod Q, and thus turn the rod once round, in the time the wheel makes one revolution. This rod, lying along a groove, in the side of a carriage of the instrument, has at its other end a square hole, into which fits the end *b* of the little cylinder P. This cylinder is disposed under the dial-plate of a movement, at the end of the carriage B, in such manner as to be moveable about its axis. Its end *a* is cut into a perpetual screw; which falling into the thirty-two teeth of a wheel perpendicular thereto, upon driving the instrument forward, that wheel makes a revolution, each fifteen poles. On the axis of this wheel is a pinion with six teeth, which, falling into the teeth of another wheel of sixty teeth, carries it round every hundred and sixtieth pole, or half a mile.

This last wheel then carrying a hand or index round with it, over the divisions of the dial-plate, whose outer limb is divided into one hundred and sixty parts, correspondling to the one hundred and sixty poles, points out the number of poles passed over. Again, on the axis of this last wheel is a pinion containing twenty teeth, which, falling into the teeth of a third wheel that has forty teeth, drives it once round in three hundred and twenty poles, or a mile. On the axis of this wheel is a pinion of twelve teeth, which, falling into the teeth of a fourth wheel, that has seventy-two teeth, drives it once round in twelve miles.

This fourth wheel carrying another index over the inner limb of the dial-plate, divided into twelve, for miles, and each mile subdivided into halves, quarters, and furlongs, serves to register the revolutions of the other hand, and to keep account of the half-miles and miles passed over, as far as twelve miles.

PERAM-

PERAMBULATOR, or *surveiser*, *ufe of the*. The application of this inftrument is obvious from its conftruction. Its proper office is in the furveying of roads, and large diftances, where a great deal of expedition, and not much accuracy, is required. It is evident, that driving it along, and obferving the hands, has the fame effect as dragging the chain, and taking account of the chains and links. See CHAIN.

PERANEMA, in *Ichthyology*, the name of a Braſilian fiſh, of the ſize of the pearch, being ten or eleven fingers in length, and about three fingers broad in the broadeſt part.

Its mouth is large and round, and has no teeth, but ſeveral very rough and ſharp prominences; its eyes are large, and it has one long fin running down the back, which is ſupported by rigid and prickly rays; its tail is not forked; its whole body is a ſilvery white, with a faint bluſh of red; its ſcales are extremely ſmall, and of a triangular figure, and its belly is very white: it is a ſea-fiſh, and is wholeſome and well-taſted.

PERANTES, the name of a ſtone mentioned with many idle ſtories of its origin, by the writers of the middle ages.

It ſeems originally to have been only a corruption of the word *peantides*, a name by which the ancients ſeem to have called our *ſtalactites* or *dropſtone*.

PER ARSIN, and *theſin*, in *Muſic*. *Per* is a Latin prepoſition, ſignifying *by*, *during*; *arſis* and *theſis* are Greek words, the firſt whereof ſignifies elevation or riſing; the ſecond poſition, or ſetting down.

Per theſin, then, ſignifies in falling, or during the latter time of the meaſure; *per arſin*, in riſing, or in the firſt time of the meaſure. A ſong, counter-point, fugue, &c. are ſaid to be *per theſin*, when the notes deſcend from acute to grave: on the contrary, they are *per arſin*, when the notes aſcend from grave to acute. See ARSIS.

Fugue per ARSIN and *theſin*. See FUGUE.

PERCA, in *Ichthyology*. See PEARCH.

PERCA *Ambimenſis*, in *Ichthyology*, the name of a freſh water fiſh, ſomewhat reſembling our pearch, but differing in that it is of a brown colour, and has ſeveral blue lines under its ſnout, and ſome blueneſs in the adjoining fins, but its back and belly fins are green. It is caught in the lakes and rivers of freſh-water, at Amboyna, and is a very delicately taſted fiſh.

PERCEPTION, *perceptio*, in *Logic*, the act of *perceiving*, or apprehending a thing, without making any affirmation, or negation. See APPREHENSION and CONCEPTION.

Some writers have confounded IDEA and *perception*, whereas theſe are clearly diſtinguiſhable as the cauſe and effect; the one is an operation of the mind, and the other the reſult of that operation.

The faculty or power of *perception*, conſtitutes what we call the UNDERSTANDING.

The faculty of *perception* ſeems to be that which conſtitutes the diſtinction between the animate and inanimate parts of the creation. Vegetables, ſome of them, have ſome degree of motion, and upon different applications of other bodies, alter their figures and motions; ſo as hence to obtain the name of *ſenſitive* plants; which, however, is the reſult of mere mechaniſm, and no otherwiſe produced than the ſhortening of a rope by the eſſuſion of water. But *perception* is a metaphyſical principle, and is found in ſome degree in all animals; and in them alone.

PERCH, *pole*, or *rod*, a long meaſure, much uſed in furveying and meaſuring of land.

Among the old Romans, and ſtill among geometricians, the *pertica*, *perch*, is ten feet; and they otherwiſe call it the *decem*, *funis*, and *decempeda*.

In England, the ſtatute *perch* contains ſixteen feet and a half; and for coppice-woods, &c. eighteen feet. Forty ſquare *perches* make a rod, and one hundred and ſixty an acre.

The cuſtomary *perch* is various in various counties: in Staffordſhire it is twenty-four feet; in the foreſt of Sherwood twenty-one, the foot there being eighteen inches, the meaſure whereof is marked in the chancel wall of Edwynſtow, and in the church of St. Mary in Nottingham.

In Herefordſhire, a *perch* of walling is ſixteen feet and a half; a *perch* of ditching twenty-one feet, &c. In France, the *perch* is from eighteen to twenty-three, and even twenty-ſeven, of their feet.

PERCH, or POLE, of a wheel carriage, is faſtened to the middle of the hind axle-tree, and paſſes between the fore axle-tree and its bolſter, being ſecured by the pole-pin, ſo as to move about it, and connecting the fore and hind carriages together. Thus, AB (*Tab.* II. *Miſcellany*, *fig.* 29) repreſents the *perch* paſſing under the body of a coach, and faſtened to the hinder axle at C. DE repreſents the fore axle, and W, W, the ſections of the wheels. It is plain, that in turning a carriage of this conſtruction, the larger the wheel, the ſooner it will ſtrike againſt the *perch*; and in the caſe repreſented in the figure, the wheel ſtrikes againſt the *perch* when the axle makes the angle deſcribed by the dotted lines D, D. On this account, the fore-wheels are uſually made ſmaller than the hind ones; and notwithſtanding this diminution of ſize, the turning of ſuch carriages is attended with great inconvenience. In order to remedy this, many expedients have been adopted, particularly in coaches, chariots, and other light vehicles, to which the crane-necked *perch* could be conveniently applied. But as this could not be adapted to the heavier kinds of carriages, and is, beſides, attended with a very conſiderable expence, Mr. Jacob has contrived a more ſimple and leſs expenſive method of attaining the propoſed end. For this purpoſe, inſtead of fixing the pin, paſſing through the *perch* at P, in the centre of the axle, he brings a projection backwards from it, as in *fig.* 30 and makes the axle with the wheels turn round the pin paſſing through that projection at P; in which caſe the angle which the wheel makes with the *perch*, becomes conſiderably leſs, before the wheel ſtrikes againſt it. So that a larger wheel, in a carriage of this conſtruction, will not touch the *perch* ſo ſoon as a ſmaller wheel in a carriage of the ordinary conſtruction; and whatever be the ſize of the wheels, the carriage will turn ſhorter than if it were conſtructed in the former method, with the centre-pin in the centre of the axle. This conſtruction is attended with no additional expence, is applicable to all kinds of carriages, and is ſtronger than the uſual mode of conſtruction. Jacob's Obſ. on the Structure and Draught of Wheel Carriages, 4to. 1773. p. 59.

PERCHANT, among *Fowlers*, a DECOY-*bird*, which the fowler has faſtened by the foot, and which flutters about the place where it is tied, to draw other birds to it, and give the fowler an occaſion of catching them.

PERCOLATION. See FILTRATION.

Many have attempted the condenſing of wines by *percolation*, or ſeparating from them that ſuperfluous moiſture or water, which dilutes them below the true ſtandard of vinous liquors, in order to make them richer, and fitter for keeping; but it does not appear that ſuch attempts have as yet ſucceeded.

PERCUNOS, the name of an ancient Pruſſian idol. See POTRIMPOS.

PERCUSSION, in *Phyſics*, the impreſſion a body makes in falling or ſtriking upon another; or the ſhock or colliſion of two moving bodies; which meeting, alter each other's motion. See MOTION.

Percuſſion is either *direct* or *oblique*. See DIRECTLY and OBLIQUE.

In bodies either perfectly hard, or perfectly ſoft, and ſo void of all elaſticity, the laws of *percuſſion* are eaſily determined; but ſince even the hardeſt bodies have their ſhare of elaſticity, and in elaſtic bodies the laws are very different, and much more intricate, having been firſt aſcertained in the Philoſophical Tranſactions, by Sir Chr. Wren, Dr. Wallis, and Mr. Huygens, we ſhall lay down each apart.

PERCUSSION, *laws of, in bodies not elaſtic*. 1. If a body in motion, as A (*Tab.* V. *Mechanics*, *fig.* 38.) ſtrike directly againſt another at reſt, B, the firſt will loſe juſt as much of its motion as it communicates to the ſecond; ſo that the two will proceed thence with an equal velocity, as if collected into one maſs.

If A therefore be triple of B, A will loſe one fourth of its motion; ſo that if before it moved through a line of twenty-four feet in a minute, it will now only move eighteen.

2. If a moving body A ſtrike againſt another already in motion, B; the firſt will increaſe the velocity of the latter, but will loſe leſs of its own motion than if the latter had been at reſt; ſince all here required is, that ſome degrees of motion be added to thoſe the latter already had, to make them both proceed with an equal velocity.

Suppoſe, e.gr. the body A, with twelve degrees of motion, to ſtrike againſt the other B, leſs by half, and at reſt, the firſt will tranſfer four degrees of its motion to the latter, and retain eight to itſelf: but if it ſtrike with twelve degrees of motion on the other already moving with three degrees, it will only communicate two degrees; for A being double of B, this needs only half the motion to make it proceed with the ſame velocity.

3. If a moving body A, ſtrike on another B, either at reſt, or moving more ſlowly, and either in the ſame direction or in a contrary one; the ſum of the momenta, if the bodies move in the ſame direction, or their difference, if they move in a contrary one, will be the ſame after the *percuſſion* as before.

4. If

4. If two equal bodies, A and B, meet each other with equal velocities; after the congreſs, they will both remain at reſt.

5. If a body A ſtrike directly on another at reſt B; its celerity after the ſtroke is to its celerity before it, as the weight of A is to the ſum of the weights of A and B: if, therefore, the weights were equal, the celerity after the ſhock will be half of what it was before it.

Thus if $A=Q$, and its velocity before the ſtroke be denominated C, and $B=q$, then QC will expreſs the whole quantity of motion before and after the ſtroke, and $\frac{QC}{Q+q}$, or, the quantity of motion divided by the weights or quantities of matter, will be equal to V the common velocity: hence we ſhall have $QC=V\times Q+q$; and, therefore $C:V::Q+q:Q$. If $Q=q$, it will be $C:V::2Q:Q::2:1$.

6. If a body in motion A ſtrike directly on another moving more ſlowly, but in the ſame direction; the velocity, after the ſtock, will be equal to the ſum of the momenta, divided by the ſum of the weights.

For the ſum of the momenta both before and after the ſtroke is $QC+qc$, c being the velocity of q or B; therefore $V=\frac{QC+qc}{Q+q}$. Hence if $Q=q$, $V=\frac{Q\times C+c}{Q\times 2}=\frac{C+c}{2}$, or half the ſum of the former velocities.

7. If two equal bodies, moving with different velocities, ſtrike directly againſt each other; after the conflict, they will proceed with the ſemi-difference of the velocities wherewith they were moved before it.

For the quantity of motion is $QC-qc$, and, therefore, $V=\frac{QC-qc}{Q+q}$: and if $Q=q$, $V=\frac{QC-Qc}{2Q}=\frac{C-c}{2}$. And if C alſo $=c$, $V=o$, and, therefore, the quantity of motion is not always the ſame, as the Cartesians maintain.

8. If two bodies, A and B, meet directly with velocities that are reciprocally as their weights; after the conflict, they will both remain at reſt: i. e. if $Q:q::c:C$, $QC=qc$, and $V=\frac{Qc-qc}{Q+q}=o$.

9. If two bodies, A and B, meet directly with the ſame velocity; the celerity, after the impulſe, will be to that before it, as the difference of the weights to their ſum. For $QC-qC=V\times Q+q$; therefore $V:C::Q-q:Q+q$.

10. If two bodies meet directly, with any velocity whatever; the celerity after the ſtroke will be equal to the difference of the momenta, divided by the ſum of the weights. For $V=\frac{QC-qc}{Q+q}$.

To determine the momentum loſt by the conflict: multiply the celerity which the body had before the conflict, into its maſs; thus you have the momentum before the conflict. In like manner, multiply the celerity after the conflict into the maſs; thus have you the momentum after the conflict. The latter momentum therefore, being ſubtracted from the former, leaves the loſs. And hence may the magnitudes of the ſtrokes be eſtimated.

Thus in the three caſes already recited, the momentum before the conflict is QC, $QC+qc$, and $QC-qc$; and V, or the celerity after the conflict, will be reſpectively $\frac{QC}{Q+q}$, $\frac{QC+qc}{Q+q}$, and $\frac{QC-qc}{Q+q}$, and the momenta of Q in the ſeveral caſes $\frac{Q^2C}{Q+q}$, $\frac{Q^2C+Qqc}{Q+q}$, and $\frac{Q^2C-Qqc}{Q+q}$: therefore the quantities of motion loſt by Q will be reſpectively $QC-\frac{Q^2C}{Q+q}=\frac{QqC}{Q+q}$, $QC-\frac{Q^2C+Qqc}{Q+q}=\frac{QCq-Qcq}{Q+q}$; and $QC-\frac{Q^2C-Qqc}{Q+q}=\frac{QqC+Qqc}{Q+q}$.

Hence it appears in the firſt caſe, that the magnitude of the ſtroke, which is as the motion loſt, will be as the celerity of the ſtriking body; for if its celerity were C, the motion loſt would be $\frac{QCq}{Q+q}$; but if it were c, the motion loſt would be $\frac{Qcq}{Q+q}$; and $\frac{QCq}{Q+q}:\frac{Qcq}{Q+q}::C:c$.

In the ſecond caſe, the magnitude of the ſtroke will be the ſame as if q had been at reſt, and Q had ſtruck it with the difference of their celerities; for the motion loſt is $\frac{QCq-Qcq}{Q+q}$; but in the caſe now ſuppoſed, the motion loſt would be $\frac{Q\times C-c}{Q+q}=\frac{QCq-Qcq}{Q+q}$.

In the third caſe, the magnitude of the ſtroke will be the ſame as if either body as q had been at reſt, and the other, as Q, had ſtruck it with the ſum of their celerities: for the motion loſt is $\frac{QqC+Qqc}{Q+q}$, and in the caſe now ſuppoſed it would be $\frac{Qq\times C+c}{Q+q}$ equal to the former. Hence it appears, that the magnitude of the ſtroke between two given bodies is always proportional to their relative, and not to their abſolute celerities.

11. A direct or perpendicular ſtroke is to an oblique one as the whole ſine is to the ſine of the angle of incidence. For let BC (*Tab.* V. *Mechanics. fig.* 87.) be the body ſtruck, A the ſtriking body, AC the oblique ſtroke, aC the perpendicular ſtroke; and the magnitude of the perpendicular ſtroke aC will be to that of the oblique ſtroke in the direction AC as aC to AB, or as AC: AB. For reſolving the force in AC into AB perpendicular to BC and AD parallel to it; and it is evident that the force in the direction AB is the only part of AC that ſtrikes BC, the other part A D being parallel to it. But the magnitude of a perpendicular ſtroke of the ſame body moving with the ſame force is to be meaſured by the line aC=AC; and therefore it is to the magnitude of the oblique ſtroke as aC to AB, i. e. as AC to AB, or as radius to the ſine of the angle of incidence.

Percussion, *laws of, in elaſtic bodies*. In bodies perfectly elaſtic, the force of elaſticity is equal to the force wherewith they are compreſſed; that is, the colliſion of two ſuch bodies on each other is equivalent to the motion which either of them would acquire, or loſe, by mere ſimple impulſe. This force exerting itſelf contrary ways, a motion equivalent thereto muſt be ſubtracted from the motion in the impelling body, and added to that in the body impelled by mere impulſe, to find their velocities after *percuſſion*. See Elasticity.

12. If a body ſtrike directly on an immoveable obſtacle, either one or both of them being elaſtic; the body will be reflected with the ſame velocity wherewith it ſtruck, and in the ſame line. For if the elaſticity were away, the whole force of the ſtriking body would be ſpent in overcoming the reſiſtance of the obſtacle; and conſequently all the motion would ceaſe: it follows, that the whole force is employed in compreſſing the elaſtic body; by which means it acquires an elaſtic force equal thereto: ſince then the elaſticity, when the compreſſing force is ſpent, reduces the body into its former ſtate, it repels the other with the ſame force wherewith it ſtruck; conſequently, it will rebound with the ſame velocity. And becauſe an elaſtic body reſtores itſelf in the ſame direction wherein it was compreſſed (there being no reaſon why it ſhould change its direction) the body will rebound in the ſame right line.

13. If an elaſtic body ſtrike obliquely on an immoveable obſtacle, it will rebound in ſuch manner as to make the angle of reflexion equal to the angle of incidence. See this demonſtrated with regard to light, by a method which applies to all impinging elaſtic bodies, under Reflection.

14. If an elaſtic body A ſtrike directly againſt another at reſt B equal to it; after *percuſſion* A will remain at reſt, and B will proceed with the ſame velocity which A had before the ſhock, and in the ſame direction.

For if the bodies were not elaſtic, each would proceed, after the ſtroke, in the ſame direction, and with half the velocity; but ſince the elaſtic force acts in the ſame direction wherein the compreſſion is made, and is equal to the compreſſing force; it repels A with half its velocity, and therefore ſtops its motion: but it drives B farther with half its velocity, and therefore acceleratas its motion. It is therefore carried after the ſhock, with the whole celerity wherewith A was carried before it, and A remains at reſt. The quantity of motion before the ſtroke is QC, and the motion loſt by *percuſſion*, being the double of that loſt between non-elaſtic bodies is $\frac{2CQq}{Q+q}$; therefore the momentum after the ſtroke will be $QC-\frac{2CQq}{Q+q}=\frac{Q^2C-QCq}{Q+q}$: and $V=\frac{QC-Cq}{Q+q}$; and the velocity of q, whoſe motion is equal to that loſt by Q, is equal to $\frac{2Qq}{Q+q}\div q=\frac{2Q}{Q+q}$. If $Q=q$, $V=\frac{QC-CQ}{Q+q}=o$; and $v=C$.

Hence, ſince *ib. Tab.* V. *Mechan. fig.* 88.) transfers all its force to B; B in like manner will transfer it to C, C again to D, and D to E. Wherefore if there be ſeveral equal elaſtic bodies, mutually touching each other, and A be ſtruck againſt B, all the intermediate ones remaining at reſt, the laſt alone, E, will be moved, and that with the velocity wherewith A ſtruck againſt B.

15. If an elaſtic body, A, ſtrike directly on another at reſt, B; its velocity, after *percuſſion*, will be to its velocity before it, as the difference of weights is to their ſum: but

but the velocity it communicates to B, is to the ſame, as double the weight of A to the ſum of the weights.

After *percuſſion*, therefore, the velocity of A is to the velocity of B, as the difference of weights to the double of A.

Thus, $V=\frac{QC-Cq}{Q+q}=\frac{Q-q\times C}{Q+q}$; therefore, $V\times\overline{Q+q}=\overline{Q-q}\times C$, conſequently, $V:C::Q-q:Q+q$. And becauſe $v=\frac{2QC}{Q+q}$, $v:C::2Q:Q+q$. Conſequently $V:v::Q-q:2Q$.

16. If a greater body ſtrike a leſs body at reſt, the velocity given to it will be leſs than the double of its own velocity. If $Q\overline{>}q$, let $Q=mq$, then $v=\frac{2QC}{Q+q}$ will be equal to $\frac{2mqC}{mq+q}=\frac{2C}{1+\frac{1}{m}}\angle 2C$.

17. The velocity which a greater body gives to a leſs body at reſt, is to that which the leſs body moved with the ſame velocity would communicate to the greater body at reſt, as the magnitude of the greater to the magnitude of the leſs body. If $Q\overline{>}q$ ſuppoſed to be at reſt, then $v=\frac{2QC}{Q+q}$; but if Q be at reſt, and q ſtrike it with the celerity C, the velocity of Q after the ſtroke would be $\frac{2qC}{q+Q}$; therefore the velocity given by the greater body is to that given by the leſs as $\frac{2QC}{Q+q}:\frac{2qC}{q+Q}::Q:q$.

18. If a greater body ſtrikes againſt a leſs, the greater body will not come to reſt, but move more ſlowly; for ſince $Q\overline{>}q$, $Q-q$ will be poſitive, and therefore, in the proportion $Q+q:Q-q::C:V$, V will be poſitive; but leſs than C, becauſe $Q-q\angle Q+q$.

19. Again, if an elaſtic body ſtrike a larger elaſtic body at reſt, the ſmaller body will always rebound, and move in a contrary direction to what it did at firſt, and alſo give the larger body a greater quantity of motion than what was originally in the ſmaller body. For as $q\overline{>}Q$, $Q-q$ will be a negative quantity, and therefore, V will be negative, or Q will move backwards. And this quantity of motion communicated, may be greater than the original motion in any ratio leſs than that of 2 to 1. For ſuppoſing the ſmall body and its velocity, to be denoted by unity, and the larger body at reſt by x, the velocity of x after the ſhock will be $\frac{2}{1+x}$, and its quantity of motion will be $\frac{2x}{1+x}$. But though the proportion of $2x$ to $1+x$ increaſes when x increaſes, yet its limit will be the proportion of 2 to 1; which is the limit to which the motion of x may approach indefinitely near.

Hence it follows, that if the force of moving bodies be meaſured by their quantity of motion, a body may, by *percuſſion*, immediately communicate a greater force than itſelf has to another, and this in any proportion leſs than double.

But if other elaſtic bodies be interpoſed, a body may mediately communicate a greater force than its own to another larger body x, in any proportion leſs than that of $x\sqrt{x}$ to 1. Thus if $x=1000000$, the body 1 with the velocity 1, may, by the means of intermediate bodies, give it the force 999000000; and the ſum of the abſolute forces of all theſe bodies taken together, ariſing from the *percuſſion*, may exceed the force of the firſt or unity, in any ratio leſs than $2x\sqrt{x}$ to 1, or 2000000000 to 1, although the relative force in all caſes remains as at firſt $=1$.

Theſe are paradoxes which cannot be urged againſt thoſe who maintain the forces of bodies to be meaſured by their maſſes and the ſquares of their velocities.

It is alſo to be obſerved, that thoſe who meaſure force by the quantity of motion, muſt deny that there is any force loſt by the impreſſions, made on ſoft bodies, or by the bending of elaſtic bodies; for if any were loſt from ſuch cauſes, the ſum of the quantities of motion of bodies moving the ſame way, could not remain the ſame before, during, and after the ſhock, which is an univerſal rule admitted by the Newtonians. But they admit that a ſpring bent between two bodies may, by unbending itſelf, generate motion in theſe bodies. Hence it follows that, according to this doctrine, though a ſpring may give motion to bodies, it cannot, by a contrary action, take it away; which ſeems no ſmall paradox. See FORCE.

20. If a body A moves towards the body C, at reſt, and an intermediate body B of a mean magnitude be placed at reſt between them, ſo that A firſt impels B, and then B impels C, a greater motion will be given to C than if A had ſtruck it directly. And if B be a mean proportional between A and C, the velocity communicated to C will be the greateſt that can be. Huygens, de Mot. Corp. ex Percuſſ. prop. 12.

In the preceding ſeries of proportional magnitudes, $B+\frac{AC}{B}\angle A+C$. For $A:B::B:C$, therefore $A-B:B::B-C:C$, and $A-B:B-C::B:C$; but $C\angle B$, therefore $B-C\angle A-B$; and therefore $B\angle A-B+C$, and $2B\angle A+C$: but $B=\frac{AC}{B}$; therefore $B+\frac{AC}{B}\angle A+C$. The ſame propoſition might be demonſtrated, if C were the greateſt body and A the leaſt.

Now it is plain, that the velocity of the body C ſtruck only by A would be $\frac{2Aa}{A+C}=\frac{4Aa}{2A+2C}$, a denoting the velocity of A: the velocity of B, ſtruck immediately by A, would be $\frac{2Aa}{A+B}=b$, b denoting the velocity of B: and, therefore, the velocity of C ſtruck by B moved with the velocity b would be $\frac{2Bb}{B+C}=\frac{2B\times 2Aa}{\overline{B+C}\times\overline{A+B}}=\frac{4BAa}{BA+BB+CA+CB}=\frac{4Aa}{A+B+\frac{CA}{B}+C}$. But $\frac{4Aa}{A+B+\frac{CA}{B}+C}:\frac{4Aa}{2A+2C}::2A+2C:A+B+\frac{CA}{B}+C$. And the ſecond antecedent is evidently greater than the ſecond conſequent; therefore the firſt antecedent is greater than the firſt conſequent. But if B were a mean proportional between A and C, $B+\frac{AC}{B}$ would be leſs than in any other caſe. For if $B=m$ the mean proportional, $B+\frac{AC}{B}=m+\frac{m^2}{m}=2m$; but if $B=m\pm D$, then $B+\frac{AC}{B}=m\pm D+\frac{AC}{m\pm D}$; i. e. $m^2\pm 2mD+D^2+AC\,(=m^2)\overline{>}2m^2\pm 2mD$.

If more bodies be interpoſed between A and C, the motion of C will be greater; and it will be the greateſt when the bodies interpoſed conſtitute a ſeries of mean propotionals between A and C. Ibid. Prop. 13.

21. If there be a ſeries of a hundred bodies in the proportion of 1, 2, 4, 8, 16, &c. and the motion begins by the greateſt body, the velocity communicated to the ſmalleſt will be to that with which the greateſt moved nearly as 2,338,500,000,000,000 to 1. And, if the motion begins by the leaſt body, the quantity of motion will be increaſed on the whole nearly as 1 to 4,677,000,000,000. But it is to be obſerved, that there is a miſtake in the impreſſion of Huygens's book, as to the firſt number, which is there printed 147600,000,000, inſtead of 2,338, &c. ſo that the velocity thus given to the ſmalleſt body is 150 times greater than what the printed copy of Huygens aſſigns. Bernoulli, Diſc. ſur. le Mouv. Oper. tom. iii. p. 34. and s'Graveſande, Præf. ad Huygen. Oper. Poſt. tom ii. Amſt. 1728.

This ſtupendous augmentation of the quantity of motion is a remarkable inſtance of the fallity of the Carteſian principle, that the ſame quantity of motion is always preſerved in the world.

Some have thought this augmentation no ſmall difficulty againſt thoſe who maintain the moving force or power of action in bodies, to be proportional to their quantities of motion. This difficulty does not preſs the Leibnitians; for it is to be obſerved, that notwithſtanding the prodigious increaſe of motion here aſſigned, yet there is no increment of the *vis viva* of this ſyſtem of bodies. See FORCE and VIS viva.

A learned author has urged, that if the force of bodies were in proportion to their quantities of motion, the increaſe in the motion here mentioned might be employed to reſtore the motion of the firſt body, and hence make a perpetual motion. But it is anſwered, that as the motion of the laſt is increaſed in the ſame direction with the firſt, the motion of all the reſt will be in the contrary direction, and equal to that of the laſt diminiſhed by unity: hence the ſum of the motions in the ſame direction remains as it did, equal to that of the firſt and ſmalleſt body, which we ſuppoſe unity. See Maclaurin's Demonſtrat. de Loix du choc des Corps, p. 21. Paris, 1724, and s'Graveſand. Rem. ſur la Poſſibilité du Mouvement perpetuel, in Journ. Liter.

It is to be obſerved, that there is a limit which the velocity communicated to the laſt body never amounts to (ſuppoſing the firſt and laſt bodies, and the velocity of the firſt before the ſtroke, to be given) but to which it approaches continually, while the number of ſuch bodies

dies interposed between the first and last is always increased. And this limit is to the velocity of the first body before the ſtroke, in the ſubduplicate ratio of the firſt body to the laſt.

Mr. Huygens has not mentioned this limit, but the curious may ſee the determination of it in Mr. Maclaurin's Fluxions, art. 514.

22. If two equal elaſtic bodies, A and B, meet directly, and with equal velocity; each will rebound with the ſame velocity wherewith it ſtruck, and alſo in the ſame direction.

For ſetting aſide the elaſticity, both would remain at reſt: their whole force therefore is ſpent in the compreſſion; but their elaſtic force whereby they rebound in the former direction is equal thereto: this force therefore acting equally on each body A and B, will produce the ſame celerity in each; and that equal to the former. So that they will rebound with the celerity wherewith they ſtruck.

23. If two equal elaſtic bodies, A and B, ſtrike directly againſt each other with unequal velocities: after the ſhock they will rebound with interchanged velocities.

For ſuppoſe the bodies to concur with the velocies $C+c$ and C: if they meet with the ſame velocity C, after the ſhock, they would both move with the ſame velocity C. If B were at reſt, and A ſhould ſtrike upon it with the celerity c after the ſhock, A would remain at reſt, and B be moved with the celerity c. Therefore the exceſs of the celerity c, wherewith A is carried, is tranſferred wholly by the conflict to B: A therefore is moved with the celerity C, and B with the celerity $C+c$.

Hence, after *percuſſion*, they recede from each other with the ſame velocity as before they concurred.

The two propoſitions in theſe two laſt articles may be proved otherwiſe thus: the momentum of Q before the ſtroke is QC; the motion loſt by it is $\frac{2QCq+2Qcq}{Q+q}$; therefore, its quantity of motion after the ſtroke will be $QC-\frac{2QCq+2Qcq}{Q+q}=\frac{Q^2C-QCq-2Qcq}{Q+q}$. Conſequently $V=\frac{QC-Cq-2qc}{Q+q}$.

The quantity of motion in q before the ſtroke is $=qc$, and that loſt by Q and acquired by q is $\frac{2QCq+2Qcq}{Q+q}$; and, therefore, its momentum after the ſtroke will be $-qc+\frac{2QCq+2Qcq}{Q+q}=\frac{2QCq-q^2c+Qcq}{Q+q}$: and $v=\frac{2QC-qc+Qc}{Q+q}$. But when $Q=q$, $V=\frac{2QC-QC-2Qc}{2Q}=-c$, and $v=\frac{2QC-Qc+Qc}{2Q}=C$.

24. If two elaſtic bodies, A and B, ſtrike directly on each other with velocities that are reciprocally proportional to their weights; after colliſion they will rebound with the ſame velocity wherewith they met.

For $Q:q::c:C$, therefore $CQ=cq$; and $V=\frac{QC-2QC-Cq}{Q+q}=-\frac{QC+Cq}{Q+q}=\frac{Q+q\times-C}{Q+q}=-C$; and $v=\frac{2qc-qc+Qc}{Q+q}=\frac{qc+Qc}{Q+q}=+c$.

25. If an elaſtic body A ſtrike on another equal one, indued with a leſs degree of motion B; after *percuſſion*, both will proceed in the ſame, *viz.* in the former direction, and with interchanged velocities.

For ſuppoſe A to ſtrike with the velocity $C+c$, upon B moving with the velocity C. Since by reaſon of the equal velocities C and C, there ariſes no impulſe; it is the ſame thing as if A ſtruck on B, with the ſole celerity c, on B at reſt. But in that caſe A would remain at reſt, and B would move with the velocity c: therefore, after *percuſſion*, A will move with the ſole celerity C, and B with the celerity $C+c$, both according to the former direction, there being nothing to change that direction.

For in this caſe, the quantity of motion in Q before the ſtroke is QC, the motion loſt by it is $\frac{2QCq-2Qcq}{Q+q}$, and the quantity of motion after the ſtroke will be $QC-\frac{2QCq-2Qcq}{Q+q}=\frac{Q^2C+2Qcq-QCq}{Q+q}$: and therefore $V=\frac{QC+2cq-Cq}{Q+q}$.

The momentum of q before the ſtroke is qc, that loſt by Q and acquired by q is $\frac{2QCq-2Qqc}{Q+q}$; therefore the momentum of q after the ſtroke will be $qc+\frac{2QCq-2Qqc}{Q+q}=\frac{q^2c+2QCq-Qqc}{Q+q}$; and $v=\frac{2QC+qc-Qc}{Q+q}$.

In the caſe here ſuppoſed $Q=q$, therefore $V=\frac{QC+2Qc-CQ}{2Q}=c$, and $v=\frac{2QC+Qc-Qc}{2Q}=C$.

26. If a moving body A ſtrike on another B; the ſtroke will be the ſame as would be made by the body A ſtriking on B at reſt, with the difference of their velocities.

Hence, ſince the elaſtic force is equal to the *percuſſion*; it acts on the bodies A and B with the difference of the velocities they had before the congreſs.

27. *To determine the velocities of any two elaſtic bodies*, A *and* B, *after ſtriking directly on each other with any velocities.* If the elaſtic body A ſtrike on B, either at reſt, or moving ſafter than A; the velocity, *v. gr.* of A after *percuſſion*, is found thus: as the ſum of the weights is to double of either of them, ſuppoſe, in this caſe, of B, ſo is the difference of the velocities before the congreſs, to a velocity, which ſubtracted from the velocity of A before the impulſe (in the other caſe added to it) leaves the velocity of A after the congreſs.

If the two elaſtic bodies, A and B, meet each other; the velocity of A, after the impulſe, is found thus: as the ſum of the weights is to the double of either of them, ſuppoſe of B, ſo is the ſum of the velocities before colliſion, to a velocity which ſubtracted from the velocity of A before colliſion, leaves its celerity after colliſion.

28. In the direct colliſion of bodies the ſame reſpective velocity is preſerved, i. e. in a direct concurrence, the difference of velocities is the ſame before and after the ſhock; and in a direct mutual encounter, the difference of velocities after the ſhock is the ſame with their ſum before it.

Hence they retire from each other, after the impulſe, with the ſame velocity wherewith they met.

Thus $v-V=C\mp c$. For $v=\frac{2QC\pm qc\mp Qc}{Q+q}$, and $V=\frac{QC\pm 2qc-Cq}{Q+q}$; therefore $v-V=\frac{2QC\pm qc\mp Qc-QC\mp 2qC+Cq}{Q+q}=\frac{QC\mp qc\mp QC+Cq}{Q+q}=\frac{Q+q\times C\mp c}{Q+q}=C\mp c$.

29. In the colliſion of elaſtic bodies there is not always preſerved the ſame momentum, or, as the Carteſians expreſs it, the ſame quantity of motion; but this is ſometimes increaſed, and ſometimes diminiſhed.

It is a miſtake, therefore, of Des Cartes, and his followers, that the ſame quantity of motion is ſtill preſerved in the world.

Thus, let q at reſt be greater than the impinging body Q; and the quantity of motion will be increaſed by colliſion: let $q=Q+x$, and C the velocity of Q: the velocity of the body q after the ſtroke will be $\frac{2QC}{Q+q}=\frac{2QC}{2Q+x}=C-\frac{xC}{2Q+x}$; but the velocity of the body Q will be $\frac{QC-Cq}{Q+q}=\frac{-xC}{2Q+x}$; therefore the abſolute momentum of q after the ſtroke will be $=q\times C-\frac{xC}{2Q+x}=\overline{Q+x}\times C-\frac{xC}{2Q+x}$.

But the momentum of the body Q is $=QC-\frac{xC}{2Q+x}$; and the quantity of motion in both bodies will be $=\frac{2Q^2C+2QxC+QxC}{2Q+x}=\frac{2Q^2C+3QxC}{2Q+x}=QC+xC-\frac{xxC}{2Q+x}$; but the quantity of motion before the ſtroke was QC, which is leſs than the former quantity, becauſe $\frac{xxC}{2Q+x}\angle xC$; for $\frac{xxC}{x}=xC$. If the bodies return to a ſecond ſtroke with the velocities acquired by the firſt, they will recover their firſt velocities, in which caſe the quantity of motion will be diminiſhed.

30. If two elaſtic bodies, A and B, meet or overtake each other directly; the ſum of the factums of the maſſes into the ſquares of the velocities remains the ſame, before and after the congreſs: hence the ſame quantity of force is likewiſe preſerved in the congreſs.

31. *To determine the motion of two bodies*, A *and* B *(fig.* 47.*) ſtriking obliquely againſt each other, whether they be elaſtic, or not elaſtic.* The motion of the body A along AC is reſoluble into two others, in the directions AE and AD; and

and the motion of B along BC into two others according to BF and BG: and the velocities through AD and BF are to the velocities through AC and BC as the right lines AD, BF, AC, BC: now since the right lines AE and BG are parallel, the forces acting according to theſe directions are not mutually oppoſite, and muſt therefore be conſidered in the congreſs.

But ſince the lines AD and BF, or, which is the ſame, EC and GC, conſtitute the ſame right line perpendicular to DC; it is the ſame as if the bodies A and B ſhould meet directly with velocities that are as EC and GC. Find, therefore, the velocity of A and B according to the rules above laid down.

Suppoſe, e. gr. the velocity of the rebounding body A to be as CH; ſince the motion along AE is not changed by the congreſs, make CK=AE, and complete the parallelogram HCKI; the diagonal CI will repreſent the motion of A after the congreſs: for, after *percuſſion*, the body will move according to the direction CI, and with a velocity as CI. In the ſame manner it will be found, that the rebounding body B will move along the diagonal of the parallelogram CM; in which LM= BG. The velocities, therefore, after *percuſſion*, are as CI to CM.

PERCUSSION, *centre of*. See CENTER *of Percuſſion*.

PER *deliquium*. See DELIQUIUM.

PER *deſcenſum*, by deſcent, in *Chemiſtry*, a particular manner of DISTILLATION.

PERDICIUM, in *Botany*, a genus of the *ſyngeneſia polygamia ſuperflua* claſs: its characters are, that it has a naked receptacle; the down is ſimple; and the corollulæ bilabiate. There are three ſpecies.

PERDIX, in *Ornithology*. See PARTRIDGE.

PERDIX, in *Conchyliology*, a name given by authors to a genus of ſhells, ſuppoſed to reſemble the partridge in the ſhades and diſpoſition of the colours.

The partridge-ſhell is of the OLIVUM, or *concha globoſa* claſs, and is ſtriated and ſpotted in a peculiarly elegant and regular manner.

PERDONATIO *ad agendas*, in *Law*, a pardon for one who is outlawed.

PERDONIUM, a term, invented by Paracelſus, to expreſs wine medicated with herbs.

PERDUE, a ſoldier placed in a dangerous, and almoſt deſperate poſt. Thus we ſay, *enfans perdues*, for the forlorn hope of an army.

The word is French, and literally ſignifies *loſt*.

To lie *perdue*, is to lie flat on the belly, or to lie cloſely in wait.

PEREGRINARY, *peregrinarius*, in the *Ancient Monaſteries*, a monk to whom was committed the care of receiving and entertaining ſtrangers, or viſitors.

PEREGRINATORES, in *Botany*, a name for ſuch ſtudents in that ſcience as have taken long journeys, and viſited the remoteſt regions, in ſearch of plants.

PEREGRINE, *peregrinus*, a term applied among *Aſtrologers*, to a planet, when found in a ſign where it has none of its five eſſential dignities.

PEREMPTORY, in *Law*, an epithet applied to an action, exception, &c. ſignifying them to be abſolute, final, and determinate; and not to be altered, renewed, or reſtrained.

Thus in our law books we find, *peremptory action*, *peremptory nonſuit*, *peremptory exemption*, &c.

PERENNIAL, in *Botany*, is applied to thoſe plants whoſe roots will endure many years.

Perennials are of two kinds: the one retain their leaves all the winter, called *evergreens*.

The other caſt the leaves in winter, called *deciduous*, or *perdeſoils*.

PERENNIAL *winds*. See WIND.

PERESKIA, in *Botany*. See *Melon* THISTLE.

PERETERION, a name given by chirurgical writers to the perforating part of the trepan.

PERFECT, ſomething to which nothing is wanting; or that has all the requiſites of its nature and kind.

PERFECT *number*, in *Arithmetic*. See NUMBER.

PERFECT, *perfecti*, in *Church Hiſtory*, a deſignation which the followers of Valentinus aſſumed to themſelves.

PERFECT, in *Grammar*. Preter or preterit-*perfect* tenſe, is an inflection, marking a time perfectly paſt; as *I have heard*: pluſquam-*perfect*, is an inflection, expreſſing the time more than perfectly paſt; as *I had heard*, &c. See TENSE.

PERFECT, in *Muſic*, denotes ſomething that fills and ſatisfies the mind, and the ear. In which ſenſe we ſay, *perfect* cadence, *perfect* concord, &c.

The ancients had two kinds of modes, the major and minor; and each of theſe, again, was either *perfect* or *imperfect*.

The word *perfect*, when joined with the words *mode*, and *time*, uſually expreſſes triple time, or meaſure; in oppoſition to double time, which they call *imperfect*. See TIME.

PERFECT, in *Phyſiology*. A *perfect* animal is uſed, by ſome writers, for that which is born by univocal generation; in oppoſition to inſects, which they pretend to be produced by equivocal GENERATION.

PERFECT *flowers* are ſuch as have petals, piſtil, ſtamina, and apices. See FLOWER.

PERFECT *mixts*. See MIXTS.

PERFECT *plants*. See PLANTS.

PERFECTION, the ſtate or quality of a thing PERFECT.

This is of divers kinds: *phyſical*, *moral*, and *metaphyſical*.

PERFECTION, *phyſical*, or *natural*, is that whereby a thing has all its powers, or faculties, and thoſe too in their full vigour; and all its parts both principal and ſecondary, and thoſe in their due proportion, conſtitution, &c. In which ſenſe a man is ſaid to be *perfect*, when he has a ſound mind in a ſound body.

This *perfection* is by the ſchoolmen frequently called ἐντελέχεια, becauſe a thing is hereby enabled to perform all its operations.

PERFECTION, *moral*, is an eminent degree of virtue, or moral goodneſs; to which men arrive by often repeated acts of piety, beneficence, &c.

This ſome ſubdivide into abſolute or *inherent*, which is actually in him to whom we attribute it; and *imputative*, which exiſts in ſome other, and not in him it is attributed to.

PERFECTION, *metaphyſical*, or *tranſcendental*, or *eſſential*, is the poſſeſſion of all the eſſential attributes, or of all the parts neceſſary to the integrity of a ſubſtance: or it is that whereby a thing has, or is provided of, every thing belonging to its nature.

This is either *abſolute*, where all imperfection is excluded; ſuch is the *perfection* of God: or *ſecundum quid*, and in its kind.

PERFECTISSIMATE, *perfectiſſimatus*, a quality, or dignity, whereof we find mention made in the code. *Perfectiſſimi* were thoſe to whom the emperors truſted the preſidentſhip of any province. Alciat imagined the name had been only given to the governors of Hiſpania Tarraconenſis, and Noricum; but Calvin has ſhewn the contrary, in his Lexicon Juridicum.

The *perfectiſſimi* were inferior to the *clariſſimi*, though the former word imply moſt perfect.

PERFIDIA, in *Muſic*, a term borrowed from the Italians, ſignifying an affectation of doing always the ſame thing, of purſuing the ſame deſign, continuing the ſame motion, the ſame ſong, the ſame paſſage, and the ſame figures, of notes.

Such are the ſtiff or conſtrained baſſes; as thoſe of chaconnes, and many others, becauſe depending wholly on the caprice of the compoſer.

PERFOLIATA, the ſame with bupleurum, or HARE'S *ear*.

PERFOLIATE-*leaf*, among *Botaniſts*. See LEAF.

PERFORANS *manus*, in *Anatomy*, a muſcle of the hand; called alſo, from its action, *flexor tertii internodii digitorum manus*. See *Tab. Anat. (Myol.) fig.* 2. *n.* 18.

It ariſes fleſhy from the fore and upper part of the ulna, and the ligament which joins that and the radius; and, after forming a pretty thick fleſhy body, it is ſplit into four round tendons; which paſſing under the annular ligament, and through the ſlits in the tendons of the former, are inſerted into the third bone of each FINGER.

PERFORANS *pedis*, in *Anatomy*, a muſcle of the foot, called alſo *profundus*; and, from its action, *flexor tertii internodii digitorum pedis*, & *flexor magnus*.

It ariſes from the upper and back part of the tibia, and, paſſing under the inner ankle, and ligament that ties the tibia and os calcis together, it divides into four tendons, which, paſſing the holes of the perforatus, are inſerted into the third phalanx of the leſſer toes.

There is a maſſa carnea, or fleſhy ſubſtance, that ariſes from the os calcis, and which joins the tendons of this muſcle where the lumbricales begin.

PERFORATA, in *Botany*, a name given by ſome authors to the *hyperieum*, or *St. John's wort*, from the ſmall holes ſeen all over its leaves, if held up to the light.

PERFORATIVE. See TREPANUM.

PERFORATUS *brachii*, in *Anatomy*, a name given by Placentini to a muſcle of the arm, now generally known by the name of the CORACO-*brachialis*. It has been by many diſputed not to be a diſtinct muſcle. Veſalius calls it only *pars interior ſi principii cubiti flectentium primi carnoſa*, eſteeming it only a part of that muſcle. Many of the writers who followed Veſalius have given it alſo the name of *pars* and *portio*, not eſteeming it a diſtinct muſcle: and Caſſerius, who wrote after Placentini, calls it only *portio carnoſa*, and cenſures that author for thinking it a diſtinct muſcle, and calling it *perforatus*.

PERFORATUS *manus*, in *Anatomy*, a muſcle of the fingers, thus called from the *perforations* of its tendons by thoſe

of the perforans: it is alſo called, ſometimes, *flexor ſecundi internodii*, from its action: and ſometimes *ſublimis*, from its ſituation. See *Tab. Anat. (Myol.) fig.* 2. *n.* 17.

It ariſes tendinous from the internal protuberance of the humerus, and the upper part of the radius before; and, being parted into four, paſſes under the annular ligament; whence it ſends ſeveral tendons into the upper part of the phalanx of each finger: every tendon having, at the firſt internode, a ſlit or perforation for the admiſſion of the tendons of the perforans.

PERFORATUS *pedis*, in *Anatomy*, a muſcle of the foot; called alſo *flexor pedis & ſublimis*.

It ariſes from the inner and lower part of the calcaneum, and ſends a tendon to every bone of the ſecond phalanx of each of the four leſs toes. In this, as alſo in the *perforatus* of the hand, there is a ſlit in each tendon about the firſt joint, which lets through the tendon of the perforans.

PERFUME, an agreeable artificial odour, ſtriking the ſenſe, or organ of ſmelling.

The generality of *perfumes* are made or compoſed of muſk, ambergriſe, civet, roſe and cedar-woods, orange-flowers, jaſmin, jonquils, tuberoſes, and other odoriferous flowers.

Therein alſo enter ſtorax, frankincenſe, benzoin, cloves, mace, and other like drugs, commonly called *aromatics*.

Some *perfumes* are alſo compoſed with aromatic herbs, or leaves, as lavender, marjoram, ſage, thyme, hyſſop, &c.

Perfumes were anciently much in uſe, particularly thoſe wherein muſk, ambergriſe, and civet enter; but they are now generally diſuſed, ſince people have become ſenſible of the harm they do the head. In Spain and Italy, however, they are ſtill very common.

PERFUMES, *ſuffitus*, in *Pharmacy*, &c. are topical or external medicines, compoſed of certain powders and gums, which, being mixed together, and thrown on the coals, produce a vapour or ſmoke, ſalutary in ſeveral diſeaſes. See SUFFITUS.

Fits of the mother are cured by the ſume of partridge-feathers, old leather, &c. Burnt mercury is ſometimes applied by way of *ſuffitus*, called fomes of cinnabar.

There are dry *perfumes*, made up in troches, pills, &c. of oilibanum, maſtic, aloes, &c. and moiſt viſcous ones mixed with the juices of herbs, &c.

PERGULARIA, in *Botany*, a genus of the *pentandria digynia* claſs: its characters are, that it is contorted; that the nectarium is formed of five parts like the points of arrows; and that the flower is monopetalous, and ſhaped like a cup or ſalver. There are two ſpecies.

PERIAGOGE, περιαγωγη, in *Rhetoric*, the ſame with PERIBOLE.

PERIAGUA, in *Sea-Language*, a ſort of large CANOE, uſed in the Leeward Iſlands, South America, and the Gulf of Mexico.

This is compoſed of the trunks of two trees hollowed and united together; and thus differs from the CANOE, which is formed of one tree.

PERIAMMA, a word uſed by ſome medical writers to expreſs an amulet.

PERIANTHIUM, or PERIANTHEUM, formed from περι, *about*, and ανθος, *flower*, in *Botany*, the little green leaves which compoſe the bottom of a flower, called, by Dr. Grew, the *empalement*, and by others the *calyx*.

The uſe of the *perianthium* is to be a ſupport, ſecurity, and as it were bands, to the other parts of the flower. Mr. Ray obſerves, that flowers, whoſe leaves or petals are ſtrong, as tulips, have no *perianthium*, as needing none. Carnations, &c. whoſe petals are long and ſlender, have their *perianthium* of one piece; others, as the knap-weed, &c. have it of ſeveral pieces, and found in divers rounds, and all with a counterchangeable reſpect to each other, for the greater ſtrength and ſecurity of themſelves, and the petals, which they include.

If it includes the ſtamina and not the germen, it is the *perianthium* of the flower; if the germen, but not the ſtamina, it is the *perianthium* of the fruit; but if it includes both, it is the *perianthium* of the fructification.

PERIAPTON, περιαπτον, a kind of medicine, otherwiſe called *periamma*, or *amulet*; which, being tied about the neck, is ſuppoſed to prevent, or cure diſeaſes.

PERIBOLE, a word uſed very frequently by Hippocrates, and, in different places, in very different ſenſes. Sometimes it ſignifies a tranſlation of the humours from one part to another; ſometimes only the dreſs or garments of a patient. In the firſt of theſe ſenſes, the word is frequently uſed to expreſs a tranſlation of the morbific matter from the centre to the ſurface, in the termination of a diſeaſe, by the breaking out of puſtules all over the body.

PERIBOLE, περιβολη, in *Rhetoric*, is uſed where many things are accumulated into one period; which might have been divided into ſeveral. We have an inſtance in Cicero's defence of Flaccus: *Quod ſi eſſet aliquando futurum ut aliquis de L. Flacci pernicie cogitaret; nunquam tamen exiſtimavit, judices, Decium Lælium, optimi viri filium, optimâ ipſum ſpe prædilum, ſummæ dignitatis, cum ſuſceptarum accuſationum, quæ ſceleratorum potius civium odia, & furori, quam ipſius virtuti, atque inſtitutæ adoleſcentiæ, conveniret.*

Now this long period might very well have been divided into the three following: 1. *Quod ſi eſſet aliquando futurum, ut aliquis de L. Flacci pernicie cogitaret; nunquam tamen exiſtimavit, judices, Decium Lælium, cum ſuſceperum accuſationem.* 2. *Eſt enim is optimi viri filius, optimâ ipſe ſpe prædilus, ſummæ dignitatis.* 3. *Accuſatio vero hæc ſceleratorum potius odia et furori, quam ipſius virtuti atque inſtitutæ adoleſcentiæ, conveniret.* See PUNCTUATION.

PERICALAMITES, in the *Materia Medica of the Ancients*, a name given by ſome to the *adarce*.

We find the word *pericalamites* in a preſcription recorded in Galen, and it has generally been underſtood to mean *ſyrus*, that being called *calamita*: but the ADARCE is the thing ſignified by the name, which expreſſes its manner of formation, it being always found concreted about the ſtalks of reeds that grow on the edges of waters.

PERICARDIARY, an epithet given to worms generated in the pericardium, or capſula of the heart.

M. Andry makes theſe one of the twelve kinds of worms engendered in the human body: they ſometimes occaſion convulſions, the paroxyſms whereof laſt but a little while, but return inceſſantly.

Theſe worms are accompanied with a frightful paleneſs of the face, a low pulſe, and violent pains of the ſtomach and breaſt.

They ſometimes occaſion a palpitation of the heart. M. Andry adds, that they have been known to occaſion ſudden death.

PERICARDIUM, περικαρδιον, formed from περι, *about*, and καρδια, *heart*, in *Anatomy*, a membranous capſule, or pouch, which includes the heart.

The *pericardium* conſiſts of three laminæ; the inner ariſing from the coats of the veſſels of the heart; the outer from the mediaſtinum; and the middle, which is the chief, is compoſed of very fine tendinous filaments, cloſely interwoven and croſſing each other in different directions. Its figure reſembles that of the heart, being conoidal; and it embraces the heart laxly, allowing room for its pulſation.

It is connected either immediately, or by veſiculæ emitted from it, to the ſternum, back, and jugulum, and in human bodies to that part of the diaphragm which anſwers to the flat or lower ſide of the heart; whereas in brutes it is looſe.

The adhering portion is in ſome meaſure of a triangular ſhape, anſwering to that of the lower ſide of the heart, but the reſt of the bag lies upon the diaphragm, without any adheſion.

Its uſe is ſuppoſed to be to defend the heart; as likewiſe to contain a loſt ſerous humour, which tranſudes through an infinite number of very ſmall holes, by which the internal lamina is perforated, and ſerves to lubricate and moiſten the heart, and to prevent any inflammation that might probably ariſe from the dry friction of the heart and its capſula.

But this latter uſe is controverted; for ſome take the humour found in it to be unnatural; and will have it forcibly ſeparated by the convulſive agonies ſupervening in the article of death.

In effect, anatomiſts are puzzled to find whence it ſhould come, or from what veſſels it is ſecreted.

Dr. Keil, in his Treatiſe of Animal Secretion, ſhews, that the liquor in the *pericardium* muſt be the moſt fluid of any ſeparated from the blood, becauſe its particles unite firſt, and are ſecreted firſt. For thoſe particles which unite firſt will have the greateſt attractive force; conſequently their particles muſt be the moſt ſpherical, and moſt ſolid; and therefore their contact will be the leaſt of any, and they the moſt fluid.

In the Memoirs of the French Academy, M. de Mortal gives an inſtance of a *pericardium*, which being opened, the liquor contained therein was found congealed into a conſiſtence fit to be cut with a knife, and lay two fingers thick about the heart.

We read of a *pericardium* of a monſtrous ſize, out of which above three pounds of congulated blood and ſerum were taken. See Medic. Eſſ. Edinb. vol. v. art. 5vi.

The *pericardium* is ſubject to inflammation, the ſymptoms and cure of which are much the ſame with thoſe of the PLEURISY.

PERICARPIA, περικαρπια, compounded of περι, *about*, and καρπος, *the wriſt*, a name ſometimes given to medicines that are applied to the wriſt: otherwiſe called EPICARPIA.

PERI-

PERICARPUS, or PERICARPIUM, formed of περὶ *about*, and καρπὸς, *fruit*, in *Botany*, a pellicle, membrane, or other ſubſtance encompaſſing the FRUIT or SEED of a plant.

It is the germen of the piſtil enlarged; or, as Linnæus defines it, it is an entrail of the plant big with ſeed, which it diſcharges when ripe. There are no leſs than nine ſpecies of *pericarpia*. 1. A capſule. 2. A conceptaculum. 3. A pod. 4. A legume. 5. A nut. 6. A drupe. 7. An apple or pomum. 8. A berry. 9. A ſtrobilus. See CAPSULE, CONCEPTACULUM, &c.

PERICHAREIA, a word uſed by the ancients to expreſs a ſudden ſurprize of joy, ſuch as has been frequently known to occaſion death.

PERICHORESIS. See CIRCUMINCESSION.

PERICHORUS, formed from περὶ, and χώρα, *country*, in *Antiquity*, a name given by the Greeks, to their profane games and combats, i. e. to ſuch as were not conſecrated to any of the gods. See GAMES.

Perichorus, in the original, ſignifies *near*, or *neighbouring*; apparently, becauſe none of the people of the neighbourhood attended at theſe obſcure exerciſes. The champions here did not fight in honour of any god, or hero, as in the others; but only for the prize-ſake.

PERICHRISIS, a word uſed by the ancients for a liniment, principally of the oleaginous or ſpirituous kinds, and as thin and fluid as oil.

PERICLASIS, a word uſed by the ancients for a fracture of a limb, attended with a large wound, by which the broken ends of the bone, or part of it, are laid bare.

PERICLYMENUM, in *Botany*. See HONEY-*ſuckle*.

PERICNEMIA, a word uſed by ſome medical writers for the parts about the calf of the leg.

PERICRANIUM, Περικράνιον, formed from περὶ, *about*, and κρανὸν, *head*, or *ſkull*, in *Anatomy*, a thick, ſolid coat or membrane, covering the outſide of the cranium, or ſkull. Some call it by the general name of *perioſteum*, becauſe of its adhering to the bone: others divide it into two membranes; the under whereof, immediately inveſting the ſkull, they call *pericraneum*, and the upper the *pericranium*. In effect, it is one double membrane, conſiſting, as moſt others do, of two coats.

It is ſuppoſed to have its origin from the dura mater; which, paſſing through the ſutures of the ſkull, by means of ſeveral filaments forms this thick membrane: at leaſt, it is found connected to the dura mater by fibres tranſmitted from it to the membrane through the futures.

About the origin of the temporal muſcles the two coats of the *pericranium* part; the outer paſſing over thoſe muſcles, and the inner ſtill adhering cloſe to the cranium.

PERIDONIUS *lapis*, in *Natural Hiſtory*, a name given by ſome of the writers of the middle ages to the *pyrites*, which they call alſo *peritbe*.

PERIDROME, *peridromus*, in the *Ancient Architecture*, the ſpace or an iſle in a PERIPTERE, between the columns and the wall.

Salmaſius obſerves, that the *peridromes* ſerved for walks among the Greeks.

PERIDROMIDES, Περιδρομίδες, in *Antiquity*. See XYSTI.

PERIDROMOS, a word uſed by the old Greek writers to expreſs the extreme edge of the hairs of the head, when hanging down in their natural form.

PERIEGETES, Περιηγητὴς, a Greek term, ſignifying a perſon who leads or conducts another about a thing, to ſhew it him, &c.

It is applied in antiquity to geographers; eſpecially to thoſe who deſcribed the ſea-coaſts: thus Dionyſius is ſtyled *periegetes*, for publiſhing a geography in hexameter verſes, which Euſtathius has commented on, both in Greek.

The name *periegetes* was alſo given to thoſe who conducted ſtrangers about in cities, to ſhew them the antiquities, monuments, curioſities, &c. thereof. Theſe were the ſame with what they now call the antiquaries in Italy.

PERIESTECOS, in *Medicine*, an epithet for diſeaſes, ſigns, and ſymptoms, which are ſalutary, and prognoſticate the future better health of the patient.

PERIGÆUM, PERIGEE, formed of περὶ and γῆ, *earth*, in *Aſtronomy*, that point of the ſun's or moon's orbit, wherein they are at their leaſt diſtance from the earth.

In which ſenſe *perigee* ſtands oppoſed to APOGEE.

PERIGEE, in the *Ancient Aſtronomy*, denotes a point in a planet's orb, wherein the center of its epicycle is at the leaſt diſtance from the earth.

PERIGRAPHE, a word uſually underſtood to expreſs a careleſs or inaccurate deſcription of any thing: but in Veſalius it is uſed to expreſs the white lines or impreſſions that appear in the muſculus rectus of the abdomen.

PERIHELIUM, formed from περὶ, and ἥλιος, *ſun*, in *Aſtronomy*, that point of the orbit of a planet, or comet, wherein it is at its leaſt diſtance from the ſun.

Perihelium ſtands oppoſed to APHELIUM. The ancient aſtronomers, inſtead of this term, uſed *perigæum*; becauſe they placed the earth in the centre.

PERILEUCOS, in the *Natural Hiſtory of the Ancients*, a name given to an agate; but not of a diſtinct ſpecies, but only a particular appearance of the lead-coloured agate, more uſually known among them by the name of PHASSACHATES.

PERILLA, in *Botany*, a genus of the *didynamia gymnoſpermia* claſs: its characters are, that the upper ſegments of the empalement are the ſhorteſt; the ſtamina are diſtant, and the ſtyles are two and connected. There is only one ſpecies.

PERIMETER, formed from περὶ, and μέτρον, *menſure*, in *Geometry*, the ambit or extent that bounds a FIGURE, or body.

The *perimeters* of ſurfaces, or figures, are lines; thoſe of bodies are ſurfaces.

In circular figures, &c. inſtead of *perimeter*, we ſay circumference or periphery.

PERINÆUM, or PERINEUM, περίναιον, or περίνεον, formed of περὶ, and νάειν, *to inhabit*, in *Anatomy*, the ſpace between the pudendum and the fundament; properly, the ligamentous ſeam which connects thoſe two parts, called by the Latins, *interfæmineum*.

This part is ſubject to laceration in a difficult birth: and in this part an operation is performed, called the puncture of the *perineum*. But the principal diſorders to which this part is ſubject, are abſceſſes and fiſtulas. See FISTULA.

PERINDE *valere*, in the *Canon Law*, a diſpenſation granted a clerk, who being legally incapable of a benefice, or other eccleſiaſtical function, is *de facto* admitted to it.

The *perinde valere* is a kind of writ, thus called from two words therein ſignifying the diſpenſation to be equivalent or tantamount to a legal capacity.

PERINEUCOS, an epithet given to a peculiar ſort of irregular pulſe common in hectic patients, in which the artery beats more ſtrongly in ſome parts than in others. See EPINEUCOS.

PERIOCHA, Περιοχὴ, an argument, indicating the ſum of a diſcourſe.

PERIOD, Περίοδος, in *Aſtronomy*, the time taken up by a ſtar or planet in making a revolution; or the duration of its courſe, till it return to the ſame point of the heavens.

The ſun's, or properly the earth's *period*, is three hundred and ſixty-five days, five hours, forty-nine minutes. That of the moon is twenty-ſeven days, ſeven hours, forty-three minutes, &c. The *periods* of the comets are now many of them pretty well aſcertained. See COMET.

There is a wonderful harmony between the diſtances of the planets from the ſun, and their *periods* found him; the great law whereof is, that the ſquares of the periodic times are ever proportional to the cubes of their mean diſtances from the ſun.

The ſeveral *periods* and mean diſtances of the ſeveral planets are as follow:

	Days	h.	′	″	mean Diſt.
Saturn	10579	6	36	26	953800
Jupiter	4332	12	20	35	520110
Mars	686	23	27	30	152369
Earth	365	6	9	30	100000
Venus	224	16	49	24	72333
Mercury	87	23	15	53	38710

See PLANETS.

PERIOD, in *Chronology*, denotes an epocha, or interval of time, by which the years are accounted; or a ſeries of years, whereby, in different nations, and on different occaſions, time is meaſured.

Such are the *Calippic*, and *Metonic periods*, two different corrections of the Greek calendar; the *Julian period*, invented by Joſeph Scaliger; the *Victorian period*, &c.

PERIOD, *Calippic*. See CALIPPIC *period*.

PERIOD, *Conſtantinopolitan*. See *Julian* PERIOD.

PERIOD, *Dionyſian*. See *Victorian* PERIOD.

PERIOD, *Hipparchus's*, is a ſeries of three hundred and four ſolar years, returning in a conſtant round, and reſtoring the new and full moons to the ſame day of the ſolar year; according to the ſentiment of Hipparchus.

This *period* ariſes by multiplying the *Calippic period* by four. Hipparchus aſſumed the quantity of the ſolar year to be 365 days, 5 hours, 55′ 12″; and hence concluded, that in one hundred and four years Calippus's *period* would err a whole day. He therefore multiplied the *period* by four, and from the product caſt away an entire day. But even this does not reſtore the new and full moons to the ſame day throughout the whole *period*: but they are ſometimes anticipated 1 day, 8 hours, 23′ 29″ 20‴.

PERIOD, *Julian*, ſo called as being adapted to the *Julian* YEAR, a ſeries of ſeven thouſand nine hundred and eighty Julian years; ariſing by the multiplication of the

cycles of the moon, the sun, and indiction, viz. 28, 19, 15, into one another; commencing from the first day of January in the Julian year.

The *Julian period* is also produced by multiplying the *Victorian period* by fifteen. Since every year in the *Julian period* has its particular cycles of the moon, sun, and indiction: e. gr. only the first has the moon's cycle one, the sun's cycle one, and cycle of indiction one; all the years of this *period* are accurately distinguished from each other.

This *period* was invented by Scaliger, as a common receptacle of epochas, to facilitate the reduction of years of a given epocha to those of another epocha likewise given. It agrees with the Constantinopolitan epocha, or *period*, used by the Greeks, except in this, that the cycles of the sun, moon, and indiction, are reckoned differently: and in that the first year of the Constantinopolitan *period* differs from that of the *Julian period*.

To find the year answering to any given year of the *Julian period*, and *vice versâ*. See EPOCHA.

PERIOD, *menstrual*, or *cycle*. See CYCLE of the *Moon*.

PERIOD, *Victorian*, an interval of five hundred and thirty-two Julian years; which elapsed, the new and full moons return on the same day of the Julian year, according to the sentiment of the inventor Victorinus, or Victorius, who lived in the time of pope Hilary.

Some ascribe this *period* to Dionysius Exiguus, and hence call it the *Dionysian period*: others call it the *great paschal cycle*; because it was invented for computing the time of Easter.

The *Victorian period* is produced by multiplying the lunar cycle nineteen, by the solar circle eighteen; the product of which is five hundred thirty-two. But neither does this restore the new and full moons to the same day throughout its whole duration, by 1 day, 16 hours, 58′ 59″ 40‴.

PERIOD, *Chaldaic*. See SAROS.

PERIOD, in *Grammar* and *Rhetoric*, denotes a little compass of discourse, containing a perfect sense; distinguished at the end by a point or full stop (.); and its members or divisions marked by commas, colons, &c.

De Colonia defines *period*, a short, but perfect sentence, consisting of certain parts or members, depending one on another, and connected together by some common vinculum.

The celebrated definition of Aristotle is, a *period* is a discourse which has a beginning, a middle, and an end, all visible at one view.

Rhetoricians consider *period*, which treats of the structure of sentences, as one of the four parts of COMPOSITION. The *periods* allowed in oratory are three: a *period* of two members, called by the Greeks *dicolos*, and the Latins *binembris*; a *period* of three members, *tricolos*, *trimembris*; and a *period* of four, *quadrimembris*, *tetracolos*.

A strict oratorial *period* does not allow of either more or fewer than these: it is possible indeed to introduce a *period* of one member, called by Aristotle *monocolos*, or simple *period*; but it will be reputed a flaw, and is a thing never practised by the masters.

The period may be likewise prolonged to five or six members; but then it changes its name, and, instead of *period*, commences what they call a *periodical discourse*.

A *period* of two members Cicero supplies us with: *Ego & mihi mea fortissimæ uxori conjunctissimo, C. Cæsar, interclusam eripuisti: & his omnibus ad bene de republica sperandum quasi signum aliquod justissimi.*

A *period* of three members the same Cicero gives us in the exordium of his *Manilian oration*: *Nam cum antea per ætatem hujus auctoritatem loci contingere non auderem; statuerumque nihil hac nisi perfectum ingenio, elaboratum industria, afferri oportere; omne meum tempus omnesque temporibus transmittendum putavi.*

A *period* of four members he gives us in that admirable description of the punishment of parricides: *Ita vivunt, ut ducere animum de cœlo non queant: ita moriuntur, ut eorum ossa terra non tangant: ita jactantur fluctibus, ut nunquam adhæreant: ita posterorum ejiciuntur, ut ne ad sacra quidem mortui conquiescant.*

The laws and measures of *periods* are pretty strictly regarded by orators, at least they are so by the ancient ones: in ordinary discourse, and in the modern tongues, authors are much less severe. In oratory, the members of *periods* are to be equal, or nearly equal; that the pauses or rests of the voice at the close of each member may be nearly equal; but in writing not intended for rehearsal, this is disregarded.

Common discourse allows of *periods* both longer and shorter than oratory; which admits of none less than two members, nor greater than four. Short mutilated *periods* break the stream, and check the course of the sublime; and long ones embarrass and keep the mind too long in suspence; and even strain the voice, which is never to stop but at the ends of *periods*. Philareus, Hermogenes, Terence, &c. confine the just *period*, called by the Latins, *ambitus* and *circuitus*, to four members: agreeable to the distich:

Quatuor è membris plenum formare videbis
Dictorum circuitum, sine ambitu ille vocetur.

Of which sentiment is Cicero, who in his Orator says, *Cingitur ille ambitus & plena comprehensio è quatuor fere partibus, quæ membra dicuntur, ut & aures impleat, & ne brevior sit quam satis sit neque longior.* An instance of a periodical discourse the same author gives us in the opening of his oration for Archias the poet: *Si quid in me ex ingenio, judices, quod sentio quam sit exiguum; aut si quis exercitatio dicendi, in qua me non infitior mediocriter esse versatum; aut si hujusce rei ratio aliqua ab optimarum artium studiis & disciplina profecta, a qua ego confiteor nullum aetatis meæ tempus abhorruisse; earum rerum omnium vel ex primis hic A. Licinius fructum a me repetere prope jure debet.*

In the formation of these *periods* two things are chiefly to be regarded, their length and cadence. As the length ought to be suited to the breath of the speaker, the ancient rhetoricians scarce admit of more than four colons. As to the cadence, what Cicero has observed is found true by experience, that the ears judge what is full, and what is deficient; and direct us to fill up our *periods*, that nothing be wanting of what they expect. When the voice is raised at the beginning of a sentence, they are in suspence till it be finished; and are pleased with a full and just cadence, but are sensible of any defect, and are displeased with redundancy. Care must, therefore, be taken, that *periods* be neither deficient, and as it were maimed, that is, that they do not drop before their time, and defraud the ears of what seemed to be promised to them; nor, on the other hand, offend them by too long and immoderate excursions. This rise and cadence of the voice in pronunciation depend on the nature and situation of the members. In a *period* of two members, the turn of the voice begins with the latter member. If a sentence consist of three members, the inflexion is best made at the end of the second member. But a *period* of four members is reckoned the most complete and perfect, where the inflection begins at the middle, that is, with the third member. An equality of the members should likewise be attended to in the composition of a *period*, the better to adjust their rise and cadence. And for this reason in sentences of three members, where the cadence begins with the third; or in those of four members where it begins at the fourth, it promotes the harmony to make the last member the longest. Ward's Or. vol. i. sect. 22.

Periods are said to be either *rotunde*, *round*, or *quadrati*, *square*, according to their different economy and cadences.

PERIOD, *square*, is that consisting of three or four equal members, formally distinguished from each other: as that of Cicero on the punishment of parricides.

PERIOD, *round*, is that whose members or parts are so connected, and fitted into each other, as that the junctures or commissures are scarce seen; but the whole slides equally round, without any notable stops or inequalities. Such are the dicolos and tricolos of Cicero above mentioned.

PERIOD is also used for the character (.) wherewith the *periods* of discourse are terminated and expressed; this is popularly called a *full stop*, or *point*. See PUNCTUATION.

Father Buffier observes two difficulties in the use of the *period*, or point: 1. e. in distinguishing it from the colon, or double point; and in determining justly the end of a *period*, or perfect sentence.

It is observed, that the supernumerary numbers of a *period*, separated from the rest by colons and semicolons, usually commence with a conjunction. Yet it is certain these same conjunctions sometimes rather begin new *periods*, than supernumerary members of old ones. It is the sense of things, and the author's own discretion, that must make the proper distinction which of the two in effect it is. No rules will here be of any service, unless this be admitted as one, that when what follows the conjunction is of as much extent as what precedes it, it is usually a new *period*; otherwise not.

The second difficulty arises hence, that the sense appears perfect in several short detached phrases, wherein it does not seem there should be *periods*: a thing frequent in free discourse; as, *We are all in suspence: make your proposals immediately: you will be to blame for detaining us longer.* Where it is evident, that simple phrases have perfect senses like *periods*, and ought to be marked accordingly; but that the shortness of the discourse making them easily comprehended, the pointing is neglected.

PERIOD, *semi*. See SEMI-*period*.

PERIOD, in *Numbers*, is a diſtinction made by a point or comma, after every ſixth place, or figure; and is uſed in numeration, for the readier diſtinguiſhing and naming the ſeveral figures or places, which ſee under NUMERATION.

PERIOD, in *Medicine*, is applied to certain diſeaſes which have intervals, and returns, to denote an entire courſe or circle, of ſuch diſeaſe; or its progreſs from any ſtate through all the reſt till it return to the ſame again.

Galen deſcribes *period* as a time compoſed of an intenſion and remiſſion; whence it is uſually divided into two parts, the paroxyſm or exacerbation, and remiſſion.

In intermitting fevers the *periods* are uſually ſtated and regular; in other diſeaſes, as the epilepſy, gout, &c. they are vague or irregular.

PERIOD is alſo uſed, by ſome writers, for the ſtate of a diſtemper, or diſeaſe.

PERIOD *of the blood*, *periodus ſanguinis*, the circle of the blood, or the tour it makes round the body, for the ſupport of life. See CIRCULATION.

PERIODEUTA, Περιοδευτὰι, a church officer among the Greeks; eſtabliſhed by the council of Laodicea, in towns, &c. where there were no biſhops.

The *periodeutæ* were a kind of rural deans; ſo called, according to Zonaras, becauſe always on the road, going from one quarter to another, to keep the people in their duty.

Hence Gregory of Theſſalonica calls them *ambulantes*, *walkers*. Balſamon calls them *exorchæ*; by which name they are known among the Greeks at this day.

PERIODIC, PERIODICAL, ſomething that terminates and comprehends a period.

PERIODICAL *month*. See MONTH.

PERIODICAL *diſeaſes* are ſuch as decline and riſe again with ſimilar ſymptoms, alternately.

In the Philoſophical Tranſactions, Dr. Muſgrave gives us an inſtance of *periodic* palſy; and Dr. Cole an inſtance of a *periodical* convulſion.

PERIODIC, in *Grammar*, is applied to a ſtyle, or diſcourſe, that has numbers, or which conſiſts of juſt and artful PERIODS.

PERIODICAL *winds*. See WIND.

PERIŒCI, Περίοικοι, formed from περὶ, *about us*, and οἶκος, *I inhabit*, in *Geography*, ſuch inhabitants of the globe as have the ſame latitudes, but oppoſite longitudes; or live under the ſame parallel, and the ſame meridian, but in different ſemicircles of that meridian, or oppoſite points of the parallel.

Theſe have the ſame common ſeaſons throughout the year, and the ſame phænomena of the heavenly bodies; but their hours, or times of the day, are oppoſite to each other. When, *v. gr.* with the one it is mid-day, with the other it is midnight.

PERIOPHTHALMIUM, compounded of περὶ, about, and ὀφθαλμὸς, *eye*, in *Natural Hiſtory*, a thin ſkin, which birds can draw over their eyes to defend them, without ſhutting their eye-lids; otherwiſe called the NICTITATING *membrane*.

PERIOSTEUM, or PERIOSTIUM, Περιοστεον, formed of περὶ, *about*, and ὀστεον, *bone*, in *Anatomy*, a membrane pretty tough, and extremely ſenſible, covering the whole exterior ſurface of all the bones of the body; the teeth only excepted. See *Tab. Anat. (Splanch.) fig.* 13. *lit. gg.* See BONE.

The *perioſteum* is derived from the dura mater, and conſiſts principally of fibres detached thence; beſides which it receives other fibres from the membrana communis of the muſcles; or, as Dr. Havers imagines, from the fleſhy fibres of the belly of the muſcles, which interſect the former. That part of it which covers the cranium, or ſkull, is by a peculiar name called the PERICRANIUM.

This membrane is extended over the cartilages and ligaments alſo, as well as the bones; but when it covers the cartilages, it is called *perichondrium*, when the ligaments, *perideſmium*.

The *perioſteum* in general is a fine ſtrong membrane, or membranous expanſion, not equally thick in all its parts, more or leſs tranſparent, of a very cloſe texture, not eaſily yielding, extremely ſenſible, and compoſed of ſeveral plains of fibres differently diſpoſed, and mixed with a great number of fine veſſels and nervous filaments.

This membrane does not immediately ſurround thoſe portions of bones which are covered by cartilages, nor thoſe in which ligaments or tendons are inſerted; neither does it cover thoſe portions of cartilages which are expoſed to friction, as in the moveable articulations, channels, &c. and, laſtly, it does not cover thoſe portions of the teeth which lie out of the ſockets and gums. The innermoſt plane of the fibrous texture of the *perioſteum*, or that which immediately adheres to the ſurface of the bones, is fixed thereto by an infinite number of ſmall fibrous extremities, brought from all the planes, and which enter the pores of the bones. Theſe extremities are accompanied by capillary veſſels and nervous filaments, which having run for ſome ſpace between the different planes of the *periſtium*, perforate the innermoſt at the orifices of the pores of the bones. The *periſteum* is of different thickneſſes, but this difference of thickneſs does not appear near ſo much on the outer ſurface, as on the inner; which is marked in many places with impreſſions, owing to the ſulci, depreſſions, lines, and inequalities on the ſurface of the bones.

Some anatomiſts have been of opinion, that this membrane was not only united to, but cloſely braced round, the bones; and that therefore it might ſet bounds to their growth. It is probable they had only examined a few bones on this occaſion, for, had they conſidered thoſe which have concave ſurfaces, depreſſions, and inequalities, they would there have found only a ſimple adheſion of the *periſteum*, without any tenſion.

In places where it is only fixed to the bone by the filaments of its innermoſt plane, it is eaſily pulled off from the bones; but where the fibres of the other planes likewiſe penetrate the bones, eſpecially when theſe planes are very numerous, and where the inſertions of tendons and ligaments mingle with theſe fibres, the ſeparation is much more difficult.

The *periſteum* in general ſerves to ſupport that admirable texture of an infinity of capillary veſſels, by which the bones and all the parts belonging to them are nouriſhed: it likewiſe ſupports a vaſt number of nervous filaments, by which ſenſation is communicated not only to this and to the internal membrane of the bones, but even, in ſome degree, to ſome portions of the bones themſelves. Winſlow.

Indeed this laſt uſe is controverted; ſome of the lateſt anatomiſts maintaining, that the *periſteum* is wholly inſenſible.

The *periſteum* is liable to inflammation from a variety of cauſes, and particularly the venereal diſeaſe and the ſcurvy; this generally terminates in an abſceſs or gangrene; if not ſpeedily removed, the bone will be injured. The cure is, in general, the ſame as in other inflammations; but the particular intention will be to carry the peccant matter outwards by fomentations and inciſions. Caſes of this kind generally terminate in amputation.

PERIPATETIC *philoſophy*, the ſyſtem of philoſophy taught and eſtabliſhed by Ariſtotle, and maintained by his followers, the *Peripatetics*.

A ſpecimen of the *Peripatetic* philoſophy, ſee under ARISTOTELIAN.

PERIPATETICS, Περιπατητικοὶ, a ſect of philoſophers, the followers of Ariſtotle, or the maintainers of the *Peripatetic* philoſophy: called alſo ARISTOTELIANS.

Cicero tells us, that Plato left two excellent diſciples, Xenocrates and Ariſtotle, who founded two ſects, which only differed in name; the former taking the appellation of ACADEMICS, who were thoſe that continued to hold their conferences in the Academy, as Plato had done before: the others, who followed Ariſtotle, were called *Peripatetics*; from περιπατέω, *I walk*; becauſe they diſputed walking in the Lyceum.

Ammonius fetches the name *Peripatetic* from Plato himſelf, who only taught walking; and adds, that the diſciples of Ariſtotle, and thoſe of Xenocrates, were equally called *Peripatetics*; the one *Peripatetics* of the Academy, the other *Peripatetics* of the Lyceum: but that, at length, the former quitted the title *Peripatetic*, for that of Academic, on occaſion of the place where they aſſembled: and the latter retained ſimply that of *Peripatetic*.

The greateſt and beſt part of Ariſtotle's philoſophy, he borrowed from his maſter Plato: Serranus affirms confidently, and ſays he is able to demonſtrate it, that there is nothing exquiſite in any part of Ariſtotle's philoſophy, dialectics, ethics, politics, phyſics, or metaphyſics, but is found in Plato. And of this opinion are many of the ancient authors, Clemens Alexandrinus, &c.

Gale endeavours to ſhew, that Ariſtotle borrowed a good deal of his philoſophy, both phyſical, about the firſt matter, and metaphyſical about the firſt being, his affections, truth, unity, goodneſs, &c. from the ſacred books; and adds, from Clearchus, one of his (Ariſtotle's) ſcholars, that he made uſe of a certain Jew, who aſſiſted him therein.

Ariſtotle's philoſophy preſerved itſelf *in puris naturalibus* for a long time: in the earlier ages of Chriſtianity, the Platonic philoſophy was more generally preferred; but this did not prevent the doctrine of Ariſtotle from forcing its way into the Chriſtian church. Towards the cloſe of the fifth century, it roſe into conſiderable credit: the Platonics, interpreting, in their ſchools, ſome of the writings of Ariſtotle, particularly his dialectics, and recommending them to young perſons. This ſeems to have been the firſt ſtep to that univerſal dominion, which

Ariſtotle

Ariſtotle afterwards obtained in the republic of letters; which was alſo very much promoted by the controverſies which Origen had occaſioned: he was zealouſly attached to the Platonic ſyſtem; and, therefore, after his condemnation, many, to avoid the imputation of his errors, and to prevent their being counted among the number of his followers, openly adopted the philoſophy of Ariſtotle. Nor was any philoſophy ſo proper for furniſhing thoſe weapons of ſubtle diſtinctions and captious ſophiſms, which were uſed in the Neſtorian, Arian, and Eutychian controverſies. About the cloſe of the ſixth century, the Ariſtotelian philoſophy, as well as ſcience in general, was almoſt univerſally decried; and it was chiefly owing to Boethius, who explained and recommended it, that it obtained a higher degree of credit among the Latins than it had hitherto enjoyed. Towards the end of the ſeventh century, the Greeks, abandoning Plato to the monks, gave themſelves up entirely to the direction of Ariſtotle, and in the ſucceeding century, the *Peripatetic* philoſophy was taught every where in their public ſchools, and propagated in all places with conſiderable ſucceſs. John Damaſcenus very much contributed to its credit and influence, by compoſing a conciſe, plain, and comprehenſive view of the doctrines of the Stagirite, for the inſtruction of the more ignorant, and in a manner adapted to common capacities. Under the patronage of Photius, and the protection of Baraas, the ſtudy of philoſophy, having for ſome time declined, revived again about the end of the ninth century. About the year 1050, a revolution in philoſophy commenced in France; when ſeveral eminent logicians, who followed Ariſtotle as their guide, took neverthleſs the liberty of illuſtrating and modelling anew his philoſophy, and extending it far beyond its ancient limits. In the twelfth century, three methods of teaching philoſophy were practiſed by different doctors; the firſt was the ancient and plain method, which confined its reſearches to the philoſophical notions of Porphyry, and the dialectic ſyſtem, commonly attributed to St. Auguſtine, and in which were laid down this general rule, that philoſophical inquiries were to be limited to a ſmall number of ſubjects, leſt, by their becoming too extenſive, religion might ſuffer by a profane mixture of human ſubtilty with its divine wiſdom. The ſecond method was called the Ariſtotelian, becauſe it conſiſted in explications of the works of that philoſopher, ſeveral of whoſe books, being tranſlated into Latin, were almoſt every where in the hands of the learned. The third was termed the free method, employed by ſuch as were bold enough to ſearch after truth, in the manner the moſt adapted to render their inquiries ſucceſsful, without rejecting the ſuccours of Ariſtotle and Plato.

A reformed ſyſtem of *Peripateticiſm* was firſt introduced into the ſchools, in the univerſity of Paris, from whence it ſoon ſpread throughout Europe; and has ſubſiſted in the univerſities to this day, under the name of *ſchool philoſophy*.

The foundation hereof is Ariſtotle's doctrine, frequently miſunderſtood, and oftener miſapplied: whence the retainers thereto may be denominated *Reformed Peripatetics*.

Out of theſe have ſprung, at ſeveral times, ſeveral branches; the chief are, the THOMISTS, SCOTISTS, and NOMINALISTS.

The *Peripatetic* ſyſtem, after having prevailed with very great and very extenſive dominion for many centuries, began rapidly to decline towards the cloſe of the ſeventeenth century, when the diſciples of Ramus attacked it on the one hand, and it had ſtill more formidable adverſaries to encounter in Des Cartes, Gaſſendi, and Newton. See ARISTOTELIAN.

PERIPETIA, Περιπετια, in the *Drama*, that part of a tragedy wherein the action is turned, the plot unravelled, and the whole concludes.

The word is formed from the Greek περιπιπτω, ſomething falling into a different ſtate; formed of περι, *about*, and πιπτω, πεσω, *I fall*.

The *peripetia* is properly the change of condition, whether happy or unhappy, which the principal perſon or perſons undergo; ariſing from ſome diſcovery, or incident, which gives a new turn to the action.

The *peripetia*, therefore, concludes with the cataſtrophe, or unravelling; unleſs we make the *peripetia* to depend on the cataſtrophe, &c. as an effect on its cauſe.

The *peripetia* is ſometimes induced by remembrance, or diſcovery; as in the Œdipus, where the meſſenger ſent from Corinth to invite Œdipus to the crown, informs him, that Polybus and Merope were not his father and mother; which begins a diſcovery, that Laius, whom he had killed, and Jocaſta, whom he had then to wife, were his father and mother, and throws him into the deepeſt diſtreſs. This inſtance Ariſtotle calls a *double peripetia*.

The qualities of the *peripetia* are, that it be probable and neceſſary; in order to which it muſt be the natural reſult, at leaſt the effect, of the foregoing action, or of the ſubject itſelf; and muſt not ſtart out from any foreign, or collateral cauſe.

Sometimes the *peripetia* is occaſioned without any diſcovery; as in the Antigone of Sophocles, where the change in Creon's fortune is produced by the effect of his own obſtinacy; and ſometimes, by a mere change of the will, which, though the leaſt artful, yet, Mr. Dryden obſerves, may be ſo managed, as to become exceedingly beautiful.

Theſe two caſes Ariſtotle calls *ſimple peripetias*; in theſe the change only conſiſts in a paſſage out of trouble and action into tranquillity and reſt. See FABLE, ACTION, &c.

PERIPHALLIA, Περιφαλλια, in *Antiquity*, the ſame with *phallagogia*. See PHALLAGOGIA and DIONYSIA.

PERIPHERY, formed from περιφερω, *I turn round*, of περι, *about*, and φερω, *I bear*, or *carry*, in *Geometry*, the circumference, or bounding-line, of a circle, ellipſis, parabola, or other regular curvilineal figure.

The *periphery* of every circle is ſuppoſed to be divided into three hundred and ſixty degrees; which are again ſubdivided, each into ſixty minutes, the minutes into ſeconds, &c.

The diviſions of degrees, therefore, are fractions, whoſe denominators proceed in a ſexagecuple ratio; as, the minute, $\frac{1}{60}$, ſecond $\frac{1}{3600}$, third $\frac{1}{216000}$. See SEXAGESIMAL.

But theſe denominators being troubleſome, in their ſtead are uſed the indices of their logarithms; hence the degree, being the integer, or unit, is marked by 0, the minute by ′, ſecond by ″, &c. See CIRCLE, and CIRCUMFERENCE.

PERIPHERY, *angle at the*. See ANGLE.

PERIPHRASIS, Περιφρασις, *circumlocution*, formed of περι, *about*, and φραζω, *I ſpeak*, in *Rhetoric*, a circuit, or tour, of words, much affected by orators, to avoid common and trite manners of expreſſion.

The *periphraſis* is of good uſe on many occaſions; and we are frequently forced to have recourſe to it, to make things be conceived which are not proper to name.

It is often a piece of politeneſs to ſuppreſs the names, and only intimate, or deſign them. Theſe turns of expreſſion are alſo particularly ſerviceable in oratory; for, the ſublime admitting of no direct citations, there muſt be a compaſs taken to inſinuate the authors whoſe authority is borrowed. A *periphraſis*, by turning round a proper name to make it underſtood, amplifies and raiſes the diſcourſe; but care muſt be taken it be not too much ſwelled, nor extended *ultra modum*; in which caſe it becomes flat and languid. See CIRCUMLOCUTION.

PERIPLOCA, in *Botany*. See *Virginian* SILK.

PERIPLUS, Περιπλους, a voyage, or navigation, round a certain ſea, or ſea-coaſt.

Arrian has deſcribed all the coaſts of the Black Sea, after having inſpected them in quality of general of the emperor Adrian; to whom he dedicates the deſcription, under the title *Periplus of the Euxine ſea*.

PERIPLYSIS, a name given by ſome authors to a diarrhœa, in which the ſtools are extremely thin and watery, and very frequent, and large in quantity.

PERIPNEUMONY, Περιπνευμονια, formed from περι, *about*, and πνευμων, *lungs*, in *Medicine*, an inflammation of ſome part of the thorax, properly of the lungs; attended with an acute fever, and a difficulty of breathing.

This diſeaſe is very frequently confounded with the PLEURISY, and then one is miſtaken for the other, ſometimes even by phyſicians. As this, however, is a diſorder of the lungs, and the other of the pleura, there are ſymptoms attending them by which they may be certainly diſtinguiſhed.

In the *peripneumony*, the pulſe is more ſoft and the pain leſs acute; but the difficulty of breathing, and oppreſſion of the breaſt are greater. The pleurify and *peripneumony* are often complicated, in which caſe the diſeaſe is called a *pleuro-peripneumony*.

The *peripneumony* is diſtinguiſhed into *vera*, or *true*; and *notha*, or *ſpurious*.

The *true* PERIPNEUMONY is a real inflammation of the ſubſtance of the lungs, attended with a ſymptomatical fever, and a cough; by the former of which it is diſtinguiſhed from an aſthma, and by the latter from a pleuriſy.

Its uſual cauſes are, want of exerciſe, hard ſtudy, ſuppreſſion of natural evacuations, a moiſt air, or the like. And the perſons moſt ſubject to it are thoſe who abound with thick blood, whoſe fibres are tenſe and rigid, who feed upon groſs aliment, and drink ſtrong viſcid liquors. It is generally fatal to thoſe who have a flat breaſt, or narrow cheſt, and to ſuch as are afflicted with an aſthma, eſpecially in the decline of life. Sometimes the inflam-

mation

mation reaches to one lobe of the lungs only; at other times the whole of this organ is afflicted; in which case, the diſeaſe can hardly fail to prove fatal. It is often occaſioned by an obſtructed perſpiration, from cold, wet clothes, &c. or by an increaſed circulation of the blood by violent exerciſe, the uſe of ſpiceries, ardent ſpirits, &c. When it ariſes from a phlegmon, the patient ſpits pure blood: when it is eryſipelatous, the ſputum is yellow, and not much tinged with red: in this laſt the breaſt is not ſo much contracted, but the fever is more violent.

The *peripneumonia* is more dangerous, though leſs painful, than the pleuriſy: its uſual way of going off is by expectoration of well concocted, reddiſh, yellow, or white matter. The flowing of the menſes, or any hæmorrhage, or diarrhœa, abſciſſes about the ears, or other parts, are alſo good prognoſtics. The medicines preſcribed are mollify the ſame that obtain in aſthmatic and pleuritic caſes. See PLEURISY.

PERIPNEUMONY, *ſperinon*, or *noſtoſpir*, is a diſeaſe of the lungs, ariſing from a heavy pituitous matter, generated throughout the whole maſs of blood, and diſcharged upon the lungs.

It is known by the viſcidity, palenеſs, and flowneſs of the blood, copiouſneſs of the ſaliva, paleneſs, and want of ſcent of the urine, ſwellings, and obſtructions in the minuter veſſels, ſhort breath, oppreſſion in the thorax, &c. Worſt of, phlegmatic, cold, phthiſical, cacarthous conſtitutions, are moſt liable to it. It begins with a feebleneſs, indolence, wearineſs, difficulty of breathing, oppreſſion of the breaſt, and feveriſhneſs; and goes on without any great appearance of danger, to death itſelf, without any certain prognoſtic thereof in the urine, pulſe, &c. It is cured by blood-letting, clyſters, thin diet, diluters, abſtergents, and aperients.

When an inflammation of the breaſt does not yield to bleeding, bliſtering, and other evacuations, it commonly ends in a ſuppuration; when this happens in the pleura, it ſometimes breaks outwardly, and the matter is diſcharged by the wound. When it happens within the ſubſtance of the lungs, the matter may be diſcharged by expectoration; but if it floats in the cavity of the breaſt, between the pleura and the lungs, it can only be diſcharged by an inciſion made betwixt the ribs. If the patient's ſtrength does not return after the inflammation is apparently removed; if his pulſe continues quick though ſoft, his breathing difficult and oppreſſed, if he has cold ſhiverings at times, his cheeks ſuſhed, his ſpeech dry, and if he complains of thirſt and want of appetite, there is reaſon to fear a ſuppuration, and that a phthiſis, or CONSUMPTION of the lungs will enſue. Buchan.

PERIPTERE, Περίπτερε, formed of περὶ, *about*, and πτέρον, *wing*; q.d. winged on every ſide, in the *Ancient Architecture*, a building encompaſſed on the outſide with a ſeries of inſulate columns, forming a kind of iſle, or portico, all around.

Such were the baſilica of Antonine, the ſeptizon of Severus, the portico of Pompey, &c.

Peripteres were properly temples which had columns on all the four ſides; by which they were diſtinguiſhed from *proſtyles*, and *amphiproſtyles*, the one of which had no columns before, and the other none on the ſides.

M. Perrault obſerves, that *peripteres*, in its general ſenſe, includes all the ſpecies of temples which have porticoes of columns all around, whether the columns be diptere, or pſeudo-diptere, or ſimple *peripteres*; which is a ſpecies that bears the name of the genus, and which has its columns diſtant from the wall by the breadth of an intercolumniation. For the difference between *peripteres* and peniſtyle, ſee PERISTYLE.

PERIPYEMA, a word uſed by chirurgical writers to expreſs a collection of matter wholly ſurrounding any part.

PERIRRHANTERION, περιῤῥαντήριον, in *Antiquity*, a veſſel, uſually of ſtone or braſs, filled with holy water, with which all thoſe that were admitted to the ſacrifices were ſprinkled; and beyond which it was unlawful for any one that was βέβηλος, or *profane*, to paſs. Some ſay it was placed in the ἄδυτα, or inmoſt recеſs of the temple, into which none entered but the prieſt; but Caſaubon will have it to be placed at the door of the temple, which opinion ſeems moſt probable, becauſe all perſons who were ἀκάθαρτοι, or *unpolluted*, were permitted to paſs beyond it.

PERISCII, περίσκιοι, q.d. *circumumbræ*, of περὶ, *about*, and σκιὰ, *ſhadow*, in *Geography*, thoſe inhabitants of the earth, whoſe ſhadows do, in one and the ſame day, ſucceſſively turn to all the points of the horizon.

Such are the inhabitants of the frozen zones, or thoſe who live within the compaſs of the arctic and antarctic circles; for, as the ſun never goes down to them after he is once up, but moves always round about, ſo do their ſhadows; inſomuch that, in the ſame day, they have their ſhadows on all ſides.

PERISCYLACISMUS, περισκυλακισμὸς, a method of purification in frequent uſe among the Greeks. It was done by drawing a whelp round the perſon to be purified.

The word comes from σκύλαξ, a *whelp*.

PERISKYTISM, *periſkyſtiſm*, formed from περὶ, and σκυτὸν, *to ſhut*, or *cut the ſkin*, in *Surgery*, an operation performed by the ancients on the CRANIUM.

The *periſkyſtiſm* is an inciſion which they made under the coronal future, reaching from one temple ſtole to the other, and penetrating to the bone of the cranium: its intention was to ſeparate the pericranium from the ſkull.

PERISSACHOREGIA, a term found in the Code, about the meaning whereof authors are much divided.

Alciat, and ſome others, will have it to be the name of an office; viz. that of curator of the annona, or proviſions; from περισσὸν, *ſuperfluous*, and χορηγεῖν, *to lead*, or *bring*. Others take it to be the office of a magiſtrate who was to look to the augmentation of the annona, and the diſtribution of the ſame. Dom. Macri will have it to ſignify a donative, or diſtribution made to the ſoldiers, over and above their pay. See DONATIVE.

PERISSON, in *Botany*, a name given by the ancient Greeks, and afterwards by the Romans, to the time of Pliny, to a kind of night-ſhade, which made thoſe people who took it internally run mad. It was alſo called *pentacoccon* and *ambrakon*, and by ſome *manicum* STRYCHNUM, or ſimply *manicon*.

PERISSOSIS, a word uſed by Hippocrates to expreſs a redundance of humours.

PERISSOLOGY, περισσολογία, in *Rhetoric*, a quality of ſtyle directly oppoſite to *brachylogy*, and is otherwiſe called *macrology*. See MACROLOGY, BRACHYLOGY, and DICTION.

PERISTALTIC, περισταλτικὸς, formed from περιστέλλω, and literally implying ſomething driven, or preſſed all around, in *Medicine*, a motion proper to the INTESTINES, wherein their ſeveral parts are ſucceſſively contracted from above downwards, or from the pylorus to the anus; in a manner ſomewhat reſembling the creeping of a worm; whence it is alſo called the *vermicular motion*.

The *periſtaltic* motion is performed by the contraction of the circular and longitudinal fibres, whereof the fleſhy coat of the inteſtines is compoſed. It is by means hereof that the chyle is driven into the orifices of the lacteal veins, and the excrements are preſſed downwards, and at laſt expelled.

When this motion comes to be depraved, and its direction changed, ſo as to proceed from below upwards, it produces what we call the ILIAC *paſſion*.

M. Perault, in an expreſs treatiſe on the *periſtaltic motion*, obſerves, that though it is ordinarily only attributed to the inteſtines, yet it is really an action common to all thoſe parts of the body which alter, prepare, concoct the ſeveral humours and ſpirits, which are the matter and inſtruments of animal action. In effect, he gives the name to all the motions whereby the cavities of the body are preſſed, or compreſſed.

PERISTAPHYLINUS, in *Anatomy*, a name which ſome give to a muſcle of the UVULA, more properly denominated PTERYGOSTAPHYLINUS.

PERISTERION, in *Botany*, a name given by ſome authors to the *ſcabiola minor*, or ſmall ſcabious.

PERISTERITES, the *pigeon-ſtone*, in *Natural Hiſtory*, a name given by ſome whimſical people to an odd conformation of a pebble, which they ſuppoſe to repreſent very exactly a pigeon without its wings. It ſeems to have been a *mere luſus naturæ*, in the formation of a common pebble. The variations of figure in the common pebbles are ſo infinite, that a perſon of a fertile imagination might find reſemblances to all the parts of the creation in the ſtones of a ſingle gravel-pit. The giving names to ſuch accidental things is not only unneceſſary, but miſchievous, as it cauſes great confuſion in natural hiſtory.

PERISTERNA, in *Anatomy*, is uſed for the lateral parts of the thorax.

PERISTIARCHUS, περισταρχὸς, in *Antiquity*, a name given to the perſon that officiated in a ſuffration.

The word comes from περισταρ, another name for καθαρματα.

PERISTOMA, in *Anatomy*, a word uſed by authors to expreſs the villous coat of the inteſtines.

PERISTYLE, περιστύλιον, formed from περὶ, *about*, and στύλος, *column*, in the *Ancient Architecture*, a place, or building, encompaſſed with a row of columns on the inſide; by which it is diſtinguiſhed from the peripтere, where the columns are diſpoſed without-ſides.

Such was the hypæthre temple of Vitruvius; and ſuch are now ſome baſilicas in Rome, ſeveral places in Italy, and moſt cloiſters of religious.

PERISTYLE *is alſo uſed*, by modern writers, for a range of columns, either within or without a building.

Thus we say, the Corinthian *peristyle* of the portal of the Louvre, &c.

PERISTYLION, *περιστυλιον*, among the Athenians, a large square place, though sometimes oblong, in the middle of the *gymnasium*, designed for walking, and the performance of those exercises which were not to be performed in the *palæstra*.

PERISYSTOLE, *περισυστολη*, in *Medicine*, the pause or interval between the two motions of the heart, or pulse; viz. that of the systole, or contraction; and that of the diastole, or dilatation.

PERITEXIS, a word used by the old medical writers to express a colliquation.

PERITHE, a name by which some of the writers of the middle ages have called the *pritis*; they say it has great virtues against the gout; some of them also have called it the *lapis perdonius*.

PERITONÆUM, or PERITONEUM, *περιτοναιον*, or *περιτονιον*, derived from the verb *περιτεινω*, *I stretch all around*, in *Anatomy*, a thin soft membrane, adhering to the inner surface of the musculi transversi, covering and containing all the viscera of the lower belly. See *Tab. Anat. Splanch. I. fig. 2. lit. n n. fig. 3. lit. b b.*

The figure and size of the *peritonæum* answer to those of the lower belly, which it lines throughout; its internal surface is smooth, and lined with an unctuous humour, serving to prevent its wounding the intestines, and other parts it touches, as well as to lubricate and facilitate their motion. When the glands which furnish it are obstructed, the *peritonæum* grows thick; as is frequently found in dropsies.

The external surface is fibrous and unequal, that it may adhere more firmly to the muscles of the abdomen, linea alba, ossa pubis, ischium, ilium sacrum, and the vertebræ lumbares, to which it is fastened; and from the last whereof many suppose it to have its origin.

The *peritonæum*, in general, is a membrane of a pretty close texture, and yet capable of a very great extension; after which it can recover itself, and be contracted to its ordinary size, as we see in pregnancy, dropsies, corpulency, and repletion.

It is also connected to the inferior, or convex surface of the liver, which it suspends; and the part employed in this action is called the *ligamentum suspensorium hepatis*.

The *peritonæum* is double every where, but most apparently so from the navel to the os pubis, and near the lumbar vertebræ, as appears, not only from its extraordinary thickness in both, but from its spontaneous parting in the latter, to receive the kidneys. But though it seems to be made up of two portions, one internal, the other external, which many anatomists have considered as a duplicature of two distinct membranous laminæ, yet, properly speaking, the internal portion alone deserves the name of a membranous lamina, as being the main body of the *peritonæum*. The external portion is no more than a kind of fibrous or follicular apophysis of the internal, and may properly enough be called the cellular substance of the *peritonæum*. It is perforated in the upper part to give passage to the œsophagus, aorta, and cava; in the under, for the fundament, the neck of the matrix, and the vessels that go to the thighs; and in the fore-part to give passage to the umbilical vessels.

Its cellular substance has two processes, which, in men, fall down into the scrotum, wrap up the spermatic vessels, and, dilating, make the tunica vaginalis of the testicles; in women, they form a cover for the round ligament of the womb.

There are other two elongations, which past under the ligamentum Fallopii, with the crural vessels, which they involve, and are gradually lost in their course downward. To these we may add a fifth, which is spread on the neck of the bladder, and, perhaps, a sixth, which accompanies the intestinum rectum. The great blood-vessels, that is, the aorta and vena cava, are likewise involved in this cellular substance of the *peritonæum*. The true lamina, or membranous portion of the *peritonæum*, is connected, by the intervention of the cellular substance, with the inner surface of the cavity of the abdomen; and has productions peculiar to itself, and very different from those of the cellular substance. Some of these are simply folded, like a duplicature; such as the membranous ligaments of the liver, colon, &c.; some are expanded like inverted bags, to contain some viscus, as the external membrane of the liver; some begin by a simple duplicature, and are afterwards expanded into a cavity, which contains some organ, as in the mesentery; some are alternately extended in the form of simple duplicatures and of cavities, as in the mesocolon; and some form only a small eminence on the inner surface of the great cavity of the *peritonæum*, as the kidneys and ureters.

The *peritonæum* receives veins and arteries from the mammariæ, diaphragmaticæ, epigastricæ, sacræ, and lumbares: nerves from the os sacrum and loins. Of Rudbeckius pretends to have likewise discovered lymphatics; but these, being scarce visible, except in hydropic cases, are not much taken notice of.

In morbid cases, great quantities of serum have been found between the duplicatures of this membrane, when there was none in the cavity of the abdomen: this constitutes the true tympany.

The use of the *peritonæum* is to contain, and keep in their place, the viscera of the abdomen, and to supply them with particular coats, &c. This is so manifest, that, whenever this membrane happens to be broken, or extraordinarily dilated, some of the parts are apt to fall down, and to form those tumors called *hernia* or *ruptures*. See HERNIA.

In the fish kind, the *peritonæum*, or membrane surrounding the abdomen, is very variously coloured. In some it is of a shining silvery whiteness, as in the cyprini, pearch, sciœnæ, &c. In others it is of a fine pale flesh-colour, as in the salmon; and in some it is wholly black, or else variegated with very numerous black spots, as in the clupeæ, gadi, couti, and spari.

PERITROCHIUM, in *Mechanics*, a wheel or circle, concentric with the base of a cylinder, and moveable together with it, about an axis. Such is the wheel AB, *Tab.* III. *Mechanics, fig.* 44. moveable on the axis EF. The axis, with the wheel, and levers fixed therein to move it, make that mechanical power, called *axis in peritrochio*.

Axis in PERITROCHIO, in *Mechanics*, one of the six mechanical powers, or simple machines, contrived for the raising of weights. See its structure, doctrine, applications, &c. under AXIS *in peritrochio*. See also MECHANICAL *powers*.

PERJURY, *perjurium*, in *Law*, the crime of swearing wilfully, absolutely, and falsly, in a lawful oath, administered in some judicial proceeding, by one who has authority, in any matter relating to an issue, or cause in question; whether it be of the person's own accord, or by subornation of another. If a man calls me *perjured*, I have my action upon the case. If he calls me *forsworn*, no action lies, because the forswearing may be extrajudicial.

Perjury is usually excepted out of general acts of grace. At common law, the punishment of *perjury*, and subornation of *perjury*, was anciently death; afterwards banishment, or cutting out the tongue; then forfeiture of goods; and now it is fine and imprisonment; and the offender is ever afterwards incapable to be a witness. 3 Inst. 163. By statute, persons committing wilful and corrupt *perjury*, in any cause depending concerning lands or goods, &c. in any of the courts of record, shall forfeit 20*l.* and be imprisoned six months, and their oaths shall not be received in any court of record, until the judgment is reversed; and if the offenders have not goods or chattels to the value of 20*l.* they shall be set on the pillory in some market-place, and have both their ears nailed to it; and unlawful and corrupt procuring and suborning a witness to give false testimony in any court of record, &c. or corruptly procuring any witness to testify *in perpetuam rei memoriam*, incurs a forfeiture of 40*l.* And if the offender be not worth 20*l.* he shall suffer six months imprisonment, and stand on the pillory in some open market, near the place where the offence was committed; and shall not be received as a witness till such judgment be reversed, the party grieved shall recover damages against the prosecutor by action on the case, &c. 5 Eliz. cap. 9. and not only in a court of record, but in any other lawful court, as a court baron, &c. *perjury* may be committed.

The statute 2 Geo. II. cap. 25. superadds a power, for the court to order the offender to be sent to the house of correction for seven years, or to be transported for the same period; and makes it felony, without benefit of clergy, to return or escape within the time. Our ancient law inflicted the punishment of deliberate murder on wilful *perjury*, when it was the cause of the death of an innocent person; and by the laws of France it is universally capital.

PERIWINKLE, in *Natural History*, the English name of a species of shells, being the *turbo littoreus* of Linnæus. It has five spires; the first ventricose; in younger subjects striated spirally; in the old smooth, and of a dusky colour. This abounds on most rocks, far above low-water mark, and is eaten in great plenty by the poor. The Swedish peasants believe, that when these shells creep high up the rocks, they indicate a storm from the south.

PERIWINKLE, *pervinca*, or *vinca*, in *Botany*, a genus of the *pentandria monogynia* class. Its characters are these: the empalement of the flower is permanent, and cut into five

five parts at the top; the flower has one falver-shaped petal, whose tube is longer than the empalement; the brim is broad, spreading open, and tightly cut into five obtuse segments; it has five very short inflexed ſtamina, terminated by erect, obtuſe ſummits; and two roundiſh germina, which have two roundiſh corpuſcles on their ſide, ſupporting one common ſtyle, the length of the ſtamina, crowned by two ſtigmas; the germen afterward turns to fruit, compoſed of two taper acute-pointed huſks, opening lengthways, with one valve, and filled with oblong cylindrical ſeeds. Miller reckons three, and Linnæus four ſpecies.

This plant deſerves a place in the ſtove, as much as any of the exotic plants we have in England; becauſe the flowers are very beautiful, and there is a conſtant ſucceſſion of them all the ſummer. Miller.

The *periwinkle* are eaſily known, even when not in flower or ſeed, by their branches being long and trailing, and their leaves ſmooth and gloſſy, and approaching to the ſhape of bay-leaves. Theſe plants ſeldom ripen their fruit; and the way to make them do it is, to plant them in a ſmall pot, and cut off all the trailing branches; by which means the nouriſhment will be carried up to the ripening of the fruit.

PERMANENT *air*, and *quantity*. See the ſubſtantives.

PERMEABLE denotes a body conſidered as its pores are capable of letting ſomewhat paſs through them. See PORE.

PER MINIMA, in *Medicine*, denotes a perfect mixture of the ſmalleſt particles of ſeveral bodies, or ingredients.

PER MINIMA, in *Pharmacy*, denotes an intimate and perfect mixture of natural bodies; wherein their very *minima*, i. e. their atoms, or firſt component particles, are ſuppoſed to be accurately blended together.

If ſilver and lead be melted together, they will thus mingle *per minima*.

PERMISSION, *permiſſio*, in *Rhetoric*, a figure which differs in nothing from CONCESSION, except that the latter relates only to argument and pleading, but the former to action: E. gr. *Quamvis, omnibus rebus exceptis, ſolum mihi ſupereſſet animus et corpus: hæc ipſa, quæ de multis relicta ſunt, vobis et veſtris caudum poteſtatis. Vos me quo patte vobis videtur, utamini, atque abutamini; licebit impune. In me quicquid libet ſtatuite*, &c.

PERMISSIVE *waſte*. See WASTE.

PERMIT, a certificate granted by exciſe officers, and ſigned by them, expreſſing the quantity of liquor, the name of buyer and ſeller, and that the duty hath been paid, or that it hath been condemned as forfeited.

PERMITTIT—*quare non* PERMITTIT. See QUARE.

PERMUTATION, the truck, or exchange, of one thing for another. See EXCHANGE.

PERMUTATION, in the *Canon Law*, a real and actual exchange of two benefices.

Permutation is a means of bringing benefices into commerce without ſimony.

The conditions required to a canonical *permutation*, are, 1. That there be benefices *permuted* on either ſide, though the revenues be unequal; and, in caſe of inequality, no compenſation is to be made in money, but only a penſion is to be charged on the greater. 2. That each of the *permutants* quit their benefices, and make a procuratiop *ad reſignandum*. 3. That the *permutation* be followed by a collation of the ordinary. 4. That the ordinary be informed of the cauſe of the *permutation*. 5. That thoſe, to whom the preſentation or election to the benefices belongs, give their conſent; or, in caſe of their refuſal, that the conſent of the dioceſan be had.

The chief rules of *permutation* are, that if one of the *compermutants* cannot enjoy, he re-enters, with full right, into the benefice he has quitted; and that, if he die before he have accompliſhed the *permutation*, on his part, by the taking of poſſeſſion, the *compermutant*, who has accompliſhed, retains both benefices, unleſs they fall into the regale.

PERMUTATIONS *of quantities*, in *Algebra*, the CHANGES, ALTERNATIONS, or different COMBINATIONS, of any number of quantities.

PERMUTATIONE *archidiaconatus, & rectoriæ eidem annexæ, cum rectoria & prebenda*, is a writ iſſued to an ordinary, commanding him to admit a clerk to a benefice upon exchange made with another. *Reg. of writs.*

PER MY *& per tout*—A joint-tenant is ſaid to be ſeiſed of the land he holds jointly, *per my & per tout*, i. e. he is ſeiſed by every parcel, and by the whole, *totum tenet, & nihil tenet; ſeu totum conjunctim, & nihil ſeparatim.* Brad.

PERNANCY, from the French *prendre, to take*, in *Law*, the taking, or receiving any thing.

Tithes, in *pernancy*, are tithes taken, or which may be taken, in kind.

PERNIO, in *Medicine*, a diſeaſe afflicting the hands and feet in the winter-time, popularly called a *kibe* or CHILBLAIN.

PERNOR *of profits*, he who takes or receives the profits of any thing. From the French *prenour, taker.*

PERONE, in *Anatomy*, a bone of the leg, more uſually called FIBULA.

PERONES, in *Roman Antiquity*, a kind of high ſhoes formed rudely of raw hides, and reaching up to the middle of the leg; though in the more ancient times of the commonwealth, the ſenators uſed them, yet in later ages they were only uſed by the ploughmen and labourers. Hence *Peronatus Avator*. Perſius, Sat. v. ver. 102. and Juvenal, Sat. 14. ver. 186.

PERONÆUS *anticus, longus, or primus*, a muſcle of the leg, ariſing fleſhy and tendinous from the head to the middle of the perone; whence, running as in a pulley, through the channel on the hind part of the outer ankle-bone, it is inſerted into the upper end of the bone of the metatarſus, which joins the great toe. The office of this muſcle is, to draw the foot upwards. See *Tab. Anat. (Myol.) fig.* 1. *n.* 65. *fig.* 2. *n.* 40. *fig.* 6. *n.* 43 *fig.* 7. *n.* 28.

PERONÆUS *maximus*, a muſcle of the leg, commonly called PERONÆUS *poſticus*.

PERONÆUS *medius*. This is commonly called *peronæus anticus*. See PERONÆUS *anticus*.

PERONÆUS *minimus*, a ſmall muſcle, vulgarly thought be a portion of the extenſor digitorum longus, though it is eaſily ſeparable from it.

It is fixed by fleſhy fibres in the lower half of the inſide of the fibula, between two oblique bony lines, on one ſide of the lower part of the extenſor digitorum longus, to which muſcle it is ſimply contiguous; from thence it runs down, contracting in breadth, and paſſes, with the extenſor longus, through the common annular ligament, forming a flat tendon, which ſoon ſeparates from thoſe of the extenſor, and is inſerted near the baſis of the fifth metatarſal bone. It is diſtinguiſhed from the other two *peronæi* by a ſeptum, or production of the ligamentary aponeuroſis of the tibia. Winſlow.

PERONÆUS *poſticus, brevis* or *ſecundus*, a muſcle ſometimes alſo called *ſemifibularis*, and *peronæus maximus*, ariſing fleſhy and ſharp on the back-part of the perone; whence continuing down the outer ſide of the bone till below the middle, it forms a ſmooth, ſtrong, flat tendon, which runs through the ſame channel at the bottom of the malleolus externus, with the longus, to the outſide of the os metatarſi of the little toe. Its office is, to pull the foot upwards. See *Tab. Anat. (Myol.) fig.* 1. *n.* 76. *fig.* 6. *n.* 44 *fig.* 7. *n.* 28.

PEROQUETTE, in *Ornithology*, the name of a ſmall ſpecies of the *pſittacus* or parrot-kind, with a long tail. See PARROT.

There are ſeveral kinds of this bird. 1. The common, which is green, red, and yellowiſh, and was the firſt ſpecies of parrot brought into Europe, and well known among the ancients. 2. The *perequito*, which is green all over, without any variegation. 3. The pale, green, and red kind. 4. The red and green-creſted kind. 5. The red kind, with wings variegated with black and green.

Beſide theſe, Margrave has deſcribed ſeven other Braſilian kinds, called the *tuiupetijuba, tuitiricica, jendaya, tuiete, tuipara, anaco*, and *quiquabatu*, and two others, to which no particular name has been given; one of the ſize of a ſwallow, all over green, with a black beak, and a very long tail; and the other of the ſize of a ſtarling, of a deep green on the back, and paler green on the belly, and with a ſhorter tail. Ray.

PERORATION, *peroratio*, in *Rhetoric*, the epilogue, or laſt part, of an oration; wherein, what the orator had inſiſted on through his whole diſcourſe, is urged afreſh, with greater vehemence and paſſion.

The *peroration* conſiſts of two parts: 1. RECAPITULATION, wherein the ſubſtance of what was diffuſed throughout the whole ſpeech, is collected briefly and curſorily, and ſummed up with new force and weight.

2. The moving the paſſions; which is ſo peculiar to the *peroration*, that the maſters of the art call this part *ſedes affectuum*.

The PASSIONS, to be raiſed in the *peroration*, are various, according to the various kinds of orations: in a panegyric, love, admiration, emulation, joy, &c. In an invective, hatred, contempt, &c. In a deliberation, hope, confidence, or fear.

The qualities required in the *peroration* are, that it be vehement and paſſionate; and that it be ſhort; becauſe, as Cicero obſerves, tears ſoon dry up.

The *peroration* was Cicero's maſter-piece: here that great orator not only ſet his judges and auditors on fire, but even ſeemed to burn himſelf; eſpecially when he was to raiſe pity and commiſeration towards the accuſed; where,

as he himself tells us, he frequently filled the forum with weeping and lamentation. He adds, that where there were several orators to speak for the same person, the *peroration* was always referred to him; and subjoins, that if he excelled herein, it was not owing to genius, but the grief himself shewed. This is abundantly evident in his Milonian *peroration*, where he says, *Sed jam sic: meum enim pro eo quod jam loqui possum, & vis & necessitas defendi vetat*—and in that for Rabirius Postumus: *Sed jam, quoniam, ut spero, fidem quam potui, vobis præstiti, Postumo, reddam etiam lachrymas quas debeo—jam indicat tot hominum lacrymæ, quam sit earum tuis, & meo dolori destitutus, includitur oratio.*

PERPENDICULAR, in *Geometry*, a line falling directly on another line, so as to make equal angles on each side; called also a *normal* line.

Thus the line IG (*Tab.* III. *Geometry, fig.* 70.) is *perpendicular* to the line KH; i. e. makes right and equal angles therewith.

From the very notion of a *perpendicular*, it follows, 1. That the *perpendicularity* is mutual; i. e. if a line, as IG, be *perpendicular* to another, KH; that other is also *perpendicular* to the first.

2. That only one *perpendicular* can be drawn from one point in the same place.

3. That if a *perpendicular* be continued through the line it was drawn *perpendicularly* to; the continuation will also be *perpendicular* to the same.

4. That if there be two points of a right line, each of which is at an equal distance from two points of another right line; that line is *perpendicular* to the other.

5. That a line, which is *perpendicular* to another, is also *perpendicular* to all the parallels of the other.

6. That a *perpendicular* line is the shortest of all those which can be drawn from the same point to the same right line.

Hence the distance of a point from a line, is a right line, drawn from the point *perpendicular* to the line or plane; and hence the altitude of a figure is a *perpendicular* let fall from the vertex to the base.

To erect a PERPENDICULAR GI on any given point G, in a right line ML: one foot of the compasses being in G, with any interval at pleasure, cut off equal parts on each side GH and GK; from the points K and H, with an interval greater than the half of KH, strike two arcs intersecting in I; the right line GI is *perpendicular* to ML.

Perpendiculars are best described in practice by means of a square; one of whose legs is applied along that line, to or from which the *perpendicular* is to be let fall or raised.

To erect a PERPENDICULAR on the end of a given line, suppose at P; open your compasses to any convenient distance, and, setting one foot in C, describe the arc RPS; lay a ruler from S through C, it will find the point R in the arc, whence draw PR, which is *perpendicular* to PM.

To let fall a PERPENDICULAR on a given line, MP, from a given point L; (*fig.* 72.) set one foot of the compasses in L, and with the other cross the given line in the points M and G. Then, setting the compasses in G and M, strike two arcs intersecting each other in *a*: then lay a ruler from L to *a*, and the line KL, described thereby, is the *perpendicular* required.

A line is said to be *perpendicular* to a plane, when it is *perpendicular* to more than two lines drawn in that plane.

A plane is said to be *perpendicular* to another plane, when a line in one plane is *perpendicular* to the other plane.

PERPENDICULAR to a curve, is a right line cutting the curve in the point in which any other right line touches it, and is also itself *perpendicular* to that tangent.

PERPENDICULAR, in *Fortification*. See FORTIFICATION, *according to Mr. Vauban's method*, and *according to ancient Pagan's method*.

PERPENDICULAR, in *Gunnery*, is a small instrument used for finding the centre line of a piece in the operation of pointing it to a given object. See *Pointing of a* GUN.

PERPENDICULARITY *of plants* is a curious phenomenon in natural history, first observed by M. Dodart, and published in an essay on the affectation of *perpendicularity* observed in the stems or stalks of all plants, in the roots of many, and even in their branches, as much as possible.

The matter of fact is, that, though almost all plants rise a little crooked, yet the stems shoot up *perpendicularly*, and the roots sink down *perpendicularly*: even such as, by the declivity of the soil, come out inclined, or such as are diverted out of the *perpendicular* by any violent means, again redress and straiten themselves, and recover their *perpendicularity*, by making a second and contrary bend or elbow, without rectifying the first. A common eye looks upon this affectation without any surprize; but a man that knows what a plant is, and how formed, finds it a subject of astonishment.

In effect, each seed contains in it a little plant, already formed, and needing nothing but to be unfolded: the little plant has its little roots and the pulp, which is usually separated into two lobes, is the foundation of the first food the plantule draws, by its root, when it begins to germinate.

Now if a seed in the earth be so disposed, as that the root of the little plant be turned downwards, and the stem upwards, and even *perpendicularly* upwards, it is easy to conceive, that the little plant coming to unfold itself, its stalk and root need only follow the direction they have, to grow *perpendicularly*. But it is known, the seeds of plants, whether sown of themselves, or by the help of man, fall in the ground at random; and among an infinite number of situations with regard to the stalk of their plant, the *perpendicular* one upwards is but one.

In all the rest, therefore, it is necessary the stalk redress or rectify itself, in order to get out of the ground: but what force is it, that effects this change, which is certainly a violent action? Is it, that the stalk, finding a less kind of earth above it, goes naturally that way where it finds the least obstacle? Were this so, the little root, when it happens to be uppermost, must, for the same reason, follow the same direction, and mount on high.

M. Dodart, therefore, to account for two such different actions, has recourse to another system: he supposes that the fibres of the stalks are of such a nature, as that they contract and shorten by the heat of the sun, and lengthen out by the moisture of the earth; and, on the contrary, that the fibres of the roots contract by the moisture of the earth, and lengthen by the heat of the sun.

When, then, the plantule is inverted, and the root is at the top, the fibres, which compose one of the branches of the root, are not equally exposed to the moisture of the earth; the lower part is more exposed than the upper. The lower therefore must contract the most; which contraction is again promoted by the lengthening of the upper, wherein the sun acts with the greatest force. Of consequence, therefore, this branch of the root must recoil towards the earth, and, insinuating through the pores thereof, must get underneath the bulb, &c. By inverting this reasoning, it is easy to shew how the stalk comes to get uppermost.

In a word, we may imagine, that the earth attracts the root to itself, and that the sun contributes to its descent; and, on the contrary, that the sun attracts the stem, and the earth, in some measure, sends it towards the same.

As to the second straitening, viz. that of the stalk in the open air, it takes it to arise from the impression of external causes, particularly the sun and rain. For the upper part of a stalk, that is bent, is more exposed to the rain, dew, and even the sun, &c. than the under. Now both these causes, in a certain structure of the fibres, tend equally to straiten the part most exposed, by the shortening they successively occasion in it; for moisture shortens by swelling, and heat by distending. Indeed, what that structure is, which gives the fibres such different qualities, or whereon it depends, is still a mystery.

M. de la Hire accounts for the *perpendicularity* of the stems or stalks of plants, thus: he imagines that, in plants, the root draws a coarser and heavier juice; and the stem and its branches a finer and more volatile one. And, in effect, most naturalists conceive the root as the stomach of the plant, where the juices of the earth are subtilized, so as to become able to rise through the stem to the extremity of the branches. This difference of juices supposes larger pores in the roots than the stalk, &c. and, in a word, a different contexture; which difference must be found even in the little invisible plant included in the seed: in this plantule, therefore, we may conceive a point of separation; such as that all on one side, e. gr. the root, shall be unfolded by the grosser juices, and all on the other side, by the more subtile juices.

Suppose, now, the plantule, when its parts begin to unfold, to be entirely inverted; the root atop, and the stalk below: the juices which enter the root will fill be constrained, and when they have opened and enlarged the pores, so as to admit juices of a determinate weight, those juices, thus pressing the root more and more, will drive it downwards; and this the more, as the root is more extended or enlarged; for the point of separation being conceived as the fixed point of a lever, they will act by the longer arm. At the same time, the volatile juices, having penetrated the stalk, will tend to give it a direction from below upwards; and, by reason of the lever, will give it more and more every day. Thus it the little plant turned on its fixed point of separation, till it be perfectly erect.

The plant thus erected, the stalk, we know, should continue to rise *perpendicularly*, to give it the more firm

bibing, and enable it to withſtand the effort of wind and weather.

The manner wherein this is effected, M. Parent lays down thus: the nutritious juice being arrived at the extremity of a riſing ſtalk, if it evaporate, the weight of the air, which encompaſſes it on all ſides, will make it aſcend vertically; and, if it do not evaporate, but congeal, and remain fixed to that extremity whence it was ready to go off, the weight of the air will give it the ſame direction; ſo that the ſtalk will have acquired a very little new part, vertically laid over it: juſt as in a candle held in any way obliquely to the horizon, the flame ſtill continues vertical, by the preſſure of the atmoſphere. The new drops of juice that ſucceed will follow the ſame direction; and, as all together form the ſtalk, that muſt of courſe be vertical, unleſs ſome particular circumſtance intervene.

As to the branches, which are at firſt ſuppoſed to proceed laterally out of the ſtalk in the firſt embryo of the plant; though they ſhould even come out in an horizontal direction, yet muſt they raiſe themſelves upwards by the conſtant direction of the nutritious juice, which at firſt ſcarce meets any reſiſtance in a tender ſupple branch; and even afterwards, though the branch grow more firm, yet will it act with the more advantage; ſince the branch, being become longer, furniſhes it with a longer arm or lever. The ſlender action of a little drop becomes very conſiderable, by its continuity, and by the aſſiſtance of ſuch favourable circumſtances. Hence may be accounted for that regular ſituation and direction of the branches, which all, and always nearly, make the ſame conſtant angle of 45° with the ſtem, and with one another.

M. Aſtruc accounts for the *perpendicularity* of the ſtems, and their redreſſing themſelves, on theſe two principles: 1. That the nutritious juice ariſes from the circumference of the plant, and terminates in the pith. 2. That fluids, contained in tubes either parallel or oblique to the horizon, gravitate on the lower part of the tubes, and not at all on the upper.

From hence it eaſily follows, that, in a plant poſited either obliquely or parallel to the horizon, the nutritious juice will act more on the lower part of the canals than the upper; and, by this means, inſinuate more into the canals communicating therewith, and be collected more copiouſly therein: thus the parts on the lower ſide will receive more accretion, and be more nouriſhed, than thoſe on the upper; the conſequence whereof muſt be, that the extremity of the plant will be obliged to bend upwards.

The ſame principle brings the ſeed into its due ſituation at firſt: in a bean, planted upſide down, the plume and radicle are eaſily perceived with the naked eye, to ſhoot, at firſt, directly, for about an inch; but thenceforth they begin to bend, the one downward, and the other upward. The like is ſeen in a heap of barley to be made into malt, or in a quantity of acorns laid to ſprout in a moiſt place, &c. each grain of barley, in the firſt caſe, and each acorn, in the ſecond, has a different ſituation; and yet all the ſprouts tend directly upward, and the roots downward, and the curvity or bend they make, is greater or leſs, as their ſituation approaches more or leſs to the direction wherein no curvature at all would be neceſſary. Now, two ſuch oppoſite motions cannot ariſe without ſuppoſing ſome conſiderable difference between the two parts: the only one we know of is, that the plume is fed by a juice, imported to it by tubes parallel to its ſides; whereas the radical imbibes its nouriſhment at all the pores in its ſurface. As oft, therefore, as the plume is either parallel or inclined to the horizon, the nutritious juice, feeding the lower parts more than the upper, will determine its extremes to turn upward, for the reaſons already aſſigned. On the contrary, when the radicle is in the like ſituation, the nutricious juice penetrating more copiouſly through the upper part than the under, there will be a greater accretion of the former than the latter; and, conſequently, the radicle will be bent downwards; and this mutual curvity of the plume and radicle muſt continue, till ſuch time as their ſides are nouriſhed alike, which cannot be till they are perpendicular. Memoires de l'Acad. Royale des Scienc. an. 1708.

PERPENDICULAR *roots*. See FIBROUS *roots*.

PERPETUAL, ſomething that endures always, or that laſts for ever.

PERPETUAL is ſometimes alſo uſed for a thing that laſts, or holds, during a perſon's life.

Thus offices, &c. held *durante vitâ*, are ſometimes called *perpetual* offices. In this ſenſe, M. Fontenelle was ſaid to be *perpetual* ſecretary of the Royal Academy of Sciences. Hence the French call him abſolutely, *M. le Perpetuel*.

PERPETUAL *action*. See ACTION.

PERPETUAL *curate*. See CURATE.

PERPETUAL *glands*, in *Anatomy*, are thoſe which are natural; thus diſtinguiſhed from the adventitious ones. See GLANDS.

PERPETUAL *lamp*. See LAMP.

PERPETUAL *motion*, in *Mechanics*. See MOTION.

Circle of PERPETUAL *acculation* and *apparition*. See CIRCLE.

PERPETUAL *pills*, *pilulæ* PERPETUÆ, among *Phyſicians*, are pills made of regulus of antimony; which, being ſwallowed and voided fifty times, will purge every time with undiminiſhed force.

PERPETUAL, or *endleſs ſcrew*. See SCREW.

PERPETUAL *virginity*. See VIRGIN.

PERPETUITY, in *Annuities*, is always the quotient of unity divided by the intereſt of 1*l.* for a year, or 100*l.* divided by the rate of intereſt. Thus, the *perpetuity* is 33-33, 28-57, 25, 20, or 16-666, according as intereſt is reckoned at 3, 3½, 4, 5, or 6 *per cent.* See ANNUITIES and ASSURANCES.

PERPETUITY, *perpetuitas*, in the *Common Law*, the quality of a benefice that is irrevocable, or whoſe incumbent cannot be deprived, except in certain caſes determined by law. It is aſſerted, with reaſon, that the *perpetuity* of benefices is eſtabliſhed by the antient canons; and that prieſts are inſeparably attached to their churches, as by a ſpiritual marriage. It is true, by the corruption of the times, the ſecular prieſts being fallen into great diſorder, and even contempt, the biſhops anciently called the religious to their aſſiſtance, and committed to them the cure of ſouls, and the adminiſtration of parihes; ſtill reſtoring them back again to their cloiſters, when they thought fit, and again revoking them *ad nutum*.

But this vague and uncertain adminiſtration only laſted to the twelfth century, when benefices returned to their eſſential *perpetuity*.

PER QUÆ *ſervitia* is a writ judicial, iſſuing on the note of a fine; and lies for the cognize of a manor, eſtignory, chief rent, or other ſervices, to compel the tenant of the land, at the time of the fine levied, to attourn to him.

PERQUISITE, *perquiſitum*, any thing gotten by a man's own induſtry, or purchaſed with his own money—In contradiſtinction to that which deſcends to him from his father, or his anceſtors.

PERQUISITES *of courts* are thoſe profits which ariſe to a lord of a manor, by virtue of his court-baron, over and above the certain yearly profits of his lands: as fines of copyholds, heriots, amerciaments, waifes, ſtrays, &c.

PER QUOD *conſortium amiſit*; or PER QUOD *ſervitium amiſit*, are words neceſſary in declarations for treſpaſs, &c. where a man's wife or ſervant is beaten or taken from him, and he loſes their ſervice, &c. 2 Lill. Abr. 595, 596.

PERRIWIG. See PERUKE.

PERRIWINKLE. See PERIWINKLE.

PERRON, in *Architecture*, a ſtaircaſe lying open, or without-ſide the building: properly, the ſteps before the front of the building, which lead into the firſt ſtory when raiſed a little above the level of the ground.

Perrons are made of different forms and ſizes, with regard to the ſpace and height they are to lead to. Sometimes the ſteps are round, or oval; more uſually they are ſquare.

PERRUKE, or PERRIWIG, was anciently uſed for a long head of natural hair; ſuch, particularly, as there was care taken in the adjuſting and trimming of.

Menage derives the word, by a long detour, from the Latin *pilus*, hair. The ſeveral ſtages of its paſſage, according to the critic, are, *pilus*, *pelus*, *pelutus*, *pelutinus*, *pelutica*, *perrutica*, *perica*, *perruque*.

The Latins called it *cæſaries*, whence part of Gaul took the denomination of *Gallia Comata*, from the long hair which the natives wore as a ſign of freedom. An antient author ſays, that Abſalom's *perruke* weighed two hundred ſhekels.

PERRUKE is now uſed for a ſet of falſe or borrowed hair, curled, buckled, and ſewed together on a frame, or cawl; anciently called *capillamentum*, or *falſe perruke*.

It is doubted, whether or no the uſe of *perrukes* was known among the ancients. It is true, they uſed falſe hair: Martial and Juvenal make merry with the women of their time, for making themſelves look young with their borrowed hair; with the men who changed their colours according to the ſeaſons; and with the dotards, who hoped to deceive the Deſtinies by their white hair. But theſe ſeem to have ſcarce had any thing in common with our *perrukes*; and were, at beſt, only compoſed of hair painted, and glued together. Nothing can be more ridiculous than the deſcription Lampridius gives of the emperor Commodus's *perruke*: it was powdered with ſcrapings of gold, and oiled (if we may uſe the expreſſion) with glutinous perfumes for the powder to hang by. In effect, the uſe of *perrukes*, at leaſt in their preſent

mode, is little more than a hundred and fifty years old; the year 1629 is reckoned the epocha of long *perukes*; at which time they began to appear in Paris; whence they spread, by degrees, throughout the east of Europe. At first it was reputed a scandal for young people to wear them, because the loss of their hair at that age was attributed to a disease, the very name whereof is a reproach; but at length the mode prevailed over the scruple, and persons of all ages and conditions have worn them; foregoing, without any necessity, the conveniences of their natural hair.

However, it was some time before the ecclesiastics came into the fashion: the first who assumed the *perruke* were some of the French clergy, in the year 1663; for it is the practice yet well authorized. The cardinal Grimaldi, in 1684, and the bishop of Lavaur, in 1688, prohibited the use of the *perruke* to all priests, without a dispensation, or necessity. M. Thiers has a treatise expressly, to prove the *perruke* indecent in an ecclesiastic, and directly contrary to the decrees and canons of councils. A priest's head, embellished with an artificial hair curiously adjusted, he esteems a monster in the church; nor can he conceive any thing so scandalous as an abbot with a florid countenance, brightened with a well-curled *perruke*.

PERRY, a drink made of pears, after the like manner as cyder is made from apples.

The best fruit, for this use, are such as are least fit for eating; e. gr. the bosbury-pear, horse-pear, barelandpear, and squab-pear. The bosbury and squab-kind, so called in Gloucestershire, have been frequently known to yield in one season, from one to four hogsheads of perry. The bosbury-pear is thought to yield the most lasting and vinous liquor; the jolly, the harpary, the drake, the mary, and the hallum-pear, and several others of the harshest kinds, are esteemed the best for *perry*; and always the redder they are, the better.

The method of preparing *perry* is perfectly the same with that of cyder. Only note, that the fruit must be perfectly ripe. Some mix crabs with them, to mend the liquor. For the duty on *perry*, see CYDER.

PER SE, in the *Schools*, is sometimes opposed to *per accidens*. In which sense, a thing is said to agree with another *per se*, when the agreement is not owing to any accidental event, but is found in the intrinsic principles of things themselves.

PER SE, is sometimes also opposed to *per aliud*. In which sense, God alone is said to have a being *per se*, as not deriving it from any other, but having it necessarily, and of himself.

PER SE, again, sometimes signifies as much as, of its own nature, or in virtue of its own entity. Thus the sun is said to give light *per se*; and thus quantity is extended *per se*.

PER SE, among *Logicians*. A thing is said to be known *per se*, *per se notum*, when we immediately perceive it upon the first proposing of the terms. As, that the whole is greater than its parts.

Philosophers go so far as to consider the mode of a thing existing *per se*, or that which constitutes its existence such; which they call *per se esse*, *per se stare*.

Object PER SE. See OBJECT.

PER SE, in *Chemistry*. When a body is distilled singly, and without the usual addition of any other matter to raise it, it is said to be distilled *per se*.

The tenuine spirits of hartshorn are those raised *per se*, in opposition to those distilled with the addition of lime.

PERSEA, in *Botany*. See BAY.

PERSECUTION, *persecutio*, literally imports any pain, affliction, or inconvenience, which a person designedly inflicts on another.

PERSECUTION more particularly denotes that tyranny which the sovereign power of any country exercises, or permits to be exercised, against those who adopt different opinions from its own in matters of religion. This kind of *persecution* is no less contrary to reason and sound policy than to the forbearing, comprehensive spirit of Christianity, and the laws of humanity. See HERESY.

PERSECUTION, as a term, is restrained to the sufferings of Christians, in behalf of their religion; particularly to those of the primitive Christians, under the heathen emperors, Nero, &c. See MARTYR.

We usually reckon ten of these persecutions: Nero set on foot the first, A. D. 65; the second happened under Domitian, A. D. 90; the third began under Trajan, A. D. 100; the fourth under Adrian, A. D. 126, which was continued under Antoninus Pius, A. D. 140; the fifth under Marcus Aurelius, A. D. 162; the sixth under Severus, A. D. 203; the seventh under Maximinus, A. D. 236; the eighth under Decius, A. D. 251; the ninth under Valerian, A. D. 258; and the tenth under Diocletian, A. D. 303.

Lactantius has written the history of the deaths of *persecutors*, though some question whether that work be really his, or not; but bishop Burnet, who has translated it into English, makes no great doubt of it.

PERSEES. See GABRES, MAGI, and ZEND.

PERSEVERANCE, in *Theology*, a Christian virtue, whereby we are enabled to persist in the way of salvation to the end.

The final *perseverance* of the saints is an article much controverted between the ARMINIANS and CALVINISTS; the latter of whom maintain it impossible for grace to be lost; and therefore make *perseverance* to the end, a necessary consequence thereof, which the former deny; esteeming the most confirmed believers never to be out of a possibility of falling.

PERSEUS, in *Astronomy*, a constellation of the northern hemisphere; whose stars, in Ptolemy's Catalogue, are 29; in Tycho's, as many; in Hevelius's 46; and in the Britannic Catalogue, 59; the longitudes, latitudes, magnitudes, &c. whereof, are as follow:

Names and situations of the stars.	Mag.	Longitud.	Latitude. North.	Magnitudes.

PERSIAN *monarchy*. See MONARCHY.

PERSIAN, or PERSIAN *tongue*, one of the living oriental languages; spoken in the empire of Persia.

The *Persian* has two particularities not found in any of the other eastern tongues: the one, that it has an auxiliary verb, answering to the *verb substantive* of the Greeks; the other that it has no *dual*. Both these it borrowed from the Macedonians, after the conquest of Alexander.

PERSIAN *wheel*, in *Agriculture*, is a machine for raising a quantity of water sufficient to overflow lands bordering on the banks of rivers, &c. where the stream is too low to do it alone.

Such a wheel is represented in *Tab.* V. *Hydraulics* and *Hydrostatics*, *fig.* 52. with which water may be raised by means of a stream AB turning a wheel CDE, according to the order of the letters, with buckets *a*, *a*, *a*, *a*, &c. hung upon the wheel by strong pins *b*, *b*, *b*, *b*, &c. fixed in the side of the rim: but the wheel must be made as high as the water is intended to be raised above the level of that part of the stream in which the wheel is placed. As the wheel turns the buckets on the right hand go down into the water, and are thereby filled, and go up full on the left hand, until they come to the top at K; where they strike against the end *n* of the fixed trough M, and are thereby overset, and empty the water into the trough; from which it may be conveyed in pipes to the place which it is designed for: and as each bucket gets over the trough, it falls into a perpendicular position again, and goes down empty, until it comes to the water at A, where it is filled as before. On each bucket is a spring *r*, which going over the top or crown of the bar *n* (fixed to the trough M) raises the bottom of the bucket above the level of its mouth, and so causes it to empty all its water into the trough.

Sometimes this wheel is made to raise water no higher than its axis; and then instead of buckets hung upon it, its spokes C, *d*, *e*, *f*, *g*, *b*, are made of a bent form, and hollow within; these hollows opening into the holes C, D, E, F, in the outside of the wheel, and also into those at O in the box N upon the axis. So that, as the holes C, D, &c. dip into the water, it runs into them; and as the wheel turns, the water rises in the hollow spokes, *e*, *d*, &c. and runs out in a stream P from the holes at O, and falls into the trough Q, from whence it is conveyed by pipes. And this is a very easy way of raising water, because the engine requires neither men nor horses to turn it. See OVERFLOWING *of land*.

PERSIAN, or PERSIC, in *Architecture*, a name common to all statues of men; serving, instead of columns, to support entablatures. See *Tab. Archit. fig.* 37.

They only differ from CARYATIDES, in that those represent statues of women.

The *Persian* is a kind of order of columns, first practised among the Athenians, on occasion of a victory their general Pausanias obtained over the *Persians*. As a trophy of this victory, the figures of men dressed in the *Persian* mode, with their hands bound before them, and other characters of slavery, were charged with the weight of Doric entablatures, and made to do the office of Doric columns.

Persian columns, M. Le Clerc observes, are not always made with the marks of slavery; but are frequently used as symbols of virtues, vices, joy, strength, valour, &c. as when made in the figures of Hercules, to represent strength; and of Mars, Mercury, fauns, satyrs, &c. on other occasions.

PERSIAN *æra*, and *year*. See EPOCHA and YEAR.

PERSIAN *bodies* and *joints*. See the substantives.

PERSICA, in *Botany*. See PEACH-*tree*.

PERSICA *concha*, in *Natural History*, a name given to a very remarkable and beautiful sea-shell, which authors have long been at a loss to reduce to any genus.

Aldrovand has thrown it to the end of his work, and says, it would be of the turbinated kind, if it did not want the turba. It is truly of the genus of the *concha globosa*, or DOLIUM.

PERSICA *terra*, in *Natural History*, an earth of the ochre kind, known in the colour-shops of London by the name of *Indian red*.

It is a very fine purple ochre, of a considerably compact texture, and great weight; while in the earth it is of a pure blood colour, and is not to be cut with the spade, but is dug with iron crows, and falls in irregular masses.

It is of a rough dusky surface, and full of considerably large, bright, glittering particles: these are white and of a fine lustre. It adheres firmly to the tongue, is rough and harsh to the touch, stains the hands very deeply, and is of a rough astringent taste, and makes a very violent effervescence with acid menstruums.

It is dug in the island of Ormus, in the Persian gulf, and in some parts of the East Indies.

PERSICARIA, in *Botany*. See ARSMART.

PERSIMON, in *Botany*. See JOA's *zizara*.

PERSOLATA, in *Botany*, a word used by Pliny, as the name of a kind of burdock, different from the *personata*. He has, in the beginning of the chapter, spoken of the arctium of the Greeks, which he says the Latins sometimes called *personata*, and afterwards adds this *persolata*; which, he says, was a plant vulgarly known, and called by the Greeks *arctium*.

He seems to allow, that the Greeks called both these plants by the same name; but he distinguishes the *persolata* from *personata*, by saying that the former has leaves like those of the great gourd, but larger and more hairy. It is probable, therefore, that he distinguishes, under these two names, the two different species of the great burdock common with us, the one with simple, the other with woolly heads.

PERSON, *persona*, an individual substance, of a rational or intelligent nature.

The father and son are reputed, in law, as the same *person*; an ambassador represents the *person* of his prince.

The word *person*, *persona*, is said to be borrowed *a personando*, from personating or counterfeiting; and is supposed to have first signified a mask: by reason, says Boethius, *in larva canorus sonus volvitur*; and hence the actors who appeared masked on the stage were sometimes called *larvati*, and sometimes *personati*.

The same author adds, that as the several actors represented each their simple individual *person*, viz. Œdipus, or Chremes, or Hecuba, or Medea; for this reason, other people, who were also distinguished by something in their form, character, &c. whereby they might be known, came also to be called, by the Latins, *personæ*; and, by the Greeks, πρόσωπα.

Again, as these actors rarely represented any but great and illustrious characters, the word came, at length, to import the mind, as being a thing of the greatest regard and dignity among human matters. And thus men, angels, and even God himself, were called *persons*. Things merely corporeal, as a stone, a plant, or a horse, were called, by them, *hypostases*, or *suppositi*, but never *persons*.

Hence also the learned imagine, the same name *person* came to be used to signify some dignity, whereby a *person* is distinguished from another; as a father, husband, judge, magistrate, &c.

In which sense we are to understand that of Cicero: Cæsar never speaks of Pompey, but in terms of honour and respect; but he does many hard and injurious things against his *person*.

This for the name *person*. As for the thing, we have already defined *person*, an individual substance of a reasonable nature; which is the same as Boethius's definition.

Now a thing may be individual two ways. 1. Logically, as it cannot be predicated of any other; as Cicero, Plato, &c. 2. Physically; in which sense a drop of water, separated from the ocean, may be called an individual. *Person* is an individual nature in each of these senses: logically, says Boethius, since *person* is not spoken of universals, but only of singulars and individuals; we do not say the *person* of an animal, or a man, but of Cicero and Plato: and physically, since Socrates's hand or foot are never considered as *persons*.

This last kind of individual is denominated two ways: positively, as when the *person* is said to be the whole principle of acting; for whatever thing action is attributed to, that do the philosophers call a *person*: and negatively, as when we say, with the Thomists, &c. that a *person* consists in this, that it does not exist in another as a more perfect being.

Thus, a man, though consisting of two very different things, viz. body and spirit, is not two *persons*; since neither part alone is a whole principle of action, but one *person*, since the manner of his consisting of body and spirit is such as constitutes one whole principle of action; nor does he exist in any other as a more perfect being; as, e. g. Socrates's foot does in Socrates, or a drop of water in the ocean.

PERSON, in *Grammar*, is a term applied to verbs and pronouns, which being conjugated, are applicable to three different *persons*.

I love, is a verb used in the first *person*; *thou lovest*, designs the second *person*; *he loveth*, marks the third: and thus in the plural number.

I, *thou*, *he*, are pronouns of the first, second, and third *person*.

Verbs agree with their nouns, in number and *person*.

PERSON, *persona*, in *Dramatic Poetry*, the name and part of an actor; or of him presented by the comedian.

At the head of dramatic pieces come the *dramatis personæ*, the list of actors, and characters that are to appear on the stage.

The ancient tragedy was only a simple chorus: Thespis

was

was the firſt who introduced a *perſon* to relieve the chorus; and Æſchylus added a ſecond.

F. Boſſu obſerves, that, in the epic and dramatic poem, the ſame *perſon* muſt reign throughout; i. e. muſt ſuſtain the chief part throughout the whole piece, and the characters of all the other *perſons* muſt be ſubordinate to him.

Quod PERSONA *nec prehendarii*, &c. See QUOD.

PERSON, *perſona*, in *Law*. See PARSON.

PERSONABLE, *perſonabilis*, in *Law*, implies the being able to hold or maintain a plea in court.

That is, as the civilians would expreſs it, *habere perſonam ſtandi in judicio*.

Thus they ſay the defendant was judged *perſonable* to maintain this action. Old Nat. Brev. 142.

The tenant pleaded, that the demandant was an alien, born in Portugal, without the ligeance of the king; and judgement was aſked, Whether he ſhould be anſwered? The plaintiff ſaid, he was made *perſonable* by parliament. Kitch. fol. 124.

PERSONABLE is alſo uſed to ſignify a capacity to take any thing granted or given.

PERSONAL, ſomething that concerns, or is reſtrained to, the *perſon*.

In diſputes among the learned, there is ever ſomething *perſonal* intermixed; in ethics, it is a maxim, that all faults are *perſonal*; i. e. they do not paſs to our deſcendants.

PERSONAL *action*, in *Law*. See ACTION.

PERSONAL *goods*, or *eſtate*, is that conſiſting of money, moveables, &c. which every perſon has in his own diſpoſal (ſee CHATTELS), in oppoſition to lands and tenements, which are called *real* ESTATE.

PERSONAL *chattels*, *covenant*, *diſtreſs*, *hiſtory*, *liberty*, *patronage*, *preſidency*, *ſervice*, and *tithes*. See the ſubſtantives.

PERSONAL, *pronoun*, or *verb* PERSONAL, in *Grammar*, a verb or pronoun conjugated in all the three perſons.

They are thus called, in oppoſition to *imperſonals*, which have only the third perſon.

PERSONALITY, *perſonalitas*, in the ſchools, the quality of a perſon; or that which conſtitutes an individual in the quality of a perſon.

The philoſophers, being uſed to conſider matter and form in every other thing, do the ſame in perſon. The matter of perſon, according to them, is a ſingular ſubſtance, endued with reaſon: for ſubſtance may, at the pleaſure of God, either be, or not be, a perſon; inaſmuch as the human nature in Chriſt is not a perſon. The form of perſon, which they call *ſubſiſtency*, *ſuppoſitality*, and *perſonality*, is that by which the foreſaid ſubſtance becomes individual.

The ſchool-divines are divided about what it is that diſtinguiſhes the ſeveral *perſonalities* in the Trinity.—Some will have it to be only the different relations: others, as Ferraventius, contend for ſome incommunicable ſubſtance: St. Bonaventure, and St. Thomas, take it to be different origins that diſtinguiſh the *perſonalities*; which opinion is the moſt followed.

PERSONALITY, or PERSONALTY, in *Law*. An action is ſaid to be in *perſonality*, when it is brought againſt the right perſon.

PERSONATA, in *Botany*. See BURDOCK.

PERSONATI, among *Botaniſts*, denote ſuch flowers as expreſs the gaping mouths of certain living creatures.

PERSONIFYING, or PERSONALIZING, the feigning a perſon; or attributing a perſon to an inanimate being; or giving it the figure, ſentiments, and language of a perſon. See PROSOPOPOEIA.

The poets have *perſonified* all the paſſions; and even made divinities of them, which were worſhipped by the heathens; as the goddeſs Perſuaſion, the god Sleep, the Furies, Envy, and Diſcord, and Fame, Fortune, Victory, &c.

Perſonifying is eſſential to poetry, eſpecially to the epopœia.

PERSPECTIVE, the art of delineating viſible objects on a plain ſurface, ſuch as they appear at a given diſtance, or height, upon a tranſparent plane, placed perpendicular to the horizon, between the eye and the object. This we particularly call

PERSPECTIVE, *linear*, as regarding the poſition, magnitude, form, &c. of the ſeveral lines, or coutours of objects, and expreſſing their diminution.

This is a branch of mathematics: ſome make it a part of optics; others a ſcience and art derived therefrom: its operations are all geometrical.

PERSPECTIVE, *hiſtory of*. The art of *perſpective* owes its birth to painting, and particularly to that branch of it which was employed in the decoration of the theatre, where landſcapes were principally introduced, and which would have looked unnatural and horrid, if the ſize of the objects had not been pretty nearly proportioned to their diſtance from the eye. The ancients muſt, therefore, have had conſiderable knowledge of this art; though the only ancient author from whom we can obtain any information, relative to its antiquity, is Vitruvius; who, in the preface to his ſeventh book, informs us, that Agatharchus, at Athens, was the firſt who wrote on this ſubject, on occaſion of a play exhibited by Æſchylus, for which he prepared a tragic ſcene; and that afterwards the principles of the art were more diſtinctly taught in the writings of Democritus and Anaxagoras, the diſciples of Agatharchus, which are no longer extant.

The *perſpective* of Euclid and of Heliodorus Larriſſæus contains only ſome general elements of optics, that are by no means adapted to any particular practice, though they furniſh ſome materials that might be of ſervice even in the linear *perſpective* of painters.

Geminus, of Rhodes, who was a celebrated mathematician, in the time of Cicero, hath likewiſe written on this ſubject.

We may alſo infer, that the Roman artiſts were acquainted with the rules of *perſpective*, from the account which Pliny, Nat. Hiſt. lib. xxxv. cap. 4. gives of the repreſentations on the ſcene of thoſe plays given by Claudius Pulcher; by whoſe appearance, he ſays, the crows were ſo deceived, that they endeavoured to ſettle on the fictitious roofs. However, of the theory of this art among the ancients we know nothing; as none of their writings have eſcaped the general wreck of ancient literature in the dark ages of Europe. *Perſpective* muſt, without doubt, have been loſt, when painting and ſculpture no longer exiſted. Nevertheleſs we have reaſon to believe, that it was practiſed much later in the Eaſtern empire.

John Tzetzes, who lived in the twelfth century, ſpeaks of it as if he was well acquainted with its importance in painting and ſtatuary: and the Greek painters, who were employed by the Venetians and Florentines, in the thirteenth century, ſeem to have brought ſome optical knowledge with them into Italy: for the diſciples of Giotto are commended for obſerving *perſpective* more regularly than any of their predeceſſors in the art had done; and they lived in the beginning of the fourteenth century.

The Arabians were not ignorant of this art; as we may preſume from the optical writings of Alhazen, who lived about the year 1100, cited by Roger Bacon, when treating on this ſubject.

Vitellus, a Polander, about the year 1270, wrote largely and learnedly on optics.

Our own friar Bacon, as well as John Peckham, archbiſhop of Canterbury, treated this ſubject with ſurpriſing accuracy, conſidering the times in which they lived.

The moſt ancient authors, who profeſſedly laid down rules of *perſpective*, were Bartolomeo Suzzaniſto, of Milan, whoſe book, intitled Regole di *Perſpettiva*, e Miſure delle Antichita di Lombardia, is dated 1440? and Pietro del Borgo, likewiſe an Italian, who was the moſt ancient author met with by Ignatius Danti, and who is ſuppoſed to have died in 1543. This laſt writer ſuppoſed objects to be placed beyond a tranſparent tablet, and endeavoured to trace the images, which rays of light emitted from them, would make upon it. But his work is not now extant. However, Albert Durer conſtructed a machine upon the principles of Borgo, by which he could trace the *perſpective* appearance of objects.

Leon Battiſta Alberti, in 1450, wrote his treatiſe De Pictura, in which he treats principally of *perſpective*.

Balthazar Peruzzi, of Siena, who died in 1536, had diligently ſtudied the writings of Borgo; and his method of *perſpective* was publiſhed by Serlio, in 1540. To him, it is ſaid, we owe the diſcovery of points of diſtance, to which all lines that make an angle of 45° with the ground line are drawn.

Guido Ubaldi, another Italian, ſoon after diſcovered, that all the lines that are parallel to one another, if they be inclined to the ground line, converge to ſome point in the horizontal line; and that through this point, alſo, a line, drawn from the eye, parallel to them, will paſs.

His *perſpective* was printed at Peſaro in 1600, and contained the firſt principles of the method afterwards diſcovered by Dr. B. Taylor.

In 1583, there was publiſhed a book, written by Giacomo Barozzi, of Vignola, commonly called Vignola, intitled The two Rules of *Perſpective*, with a learned Comment, by Ignatius Danti. In 1615, the work of Marolois was printed, in Latin, at the Hague, and engraved and publiſhed by Hondius. And in 1625, Sirigatti publiſhed a treatiſe of *perſpective*, which is little more than an abſtract of Vignola's.

The art of *perspective* has been gradually improved by subsequent gemmetricians, particularly by professor 'Gravesande, and, in a much greater degree, by Dr. Brook Taylor, whose principles are in a considerable measure new, and far more general than those of any of his predecessors. He did not confine his rules, as his predecessors had done, to the horizontal plane only, but made them general, so as to affect every species of planes and lines, whether they were parallel to the horizon or not; and thus his principles were made universal. Farther, from the simplicity of his rules, the whole tedious progress of drawing out plans and elevations for any object is rendered entirely useless, and therefore avoided; for by this method, not only the fewest lines imaginable are required to produce any *perspective* representation, but every figure, thus drawn, will bear the nicest mathematical examination. Moreover, his system is the only one calculated for answering every end of those, who are practitioners in the art of design; because from hence they may be enabled to produce the whole, or only so much of an object as is wanted, and by fixing it in its proper place, may determine its apparent magnitude in an instant. It explains also the *perspective* of shadows, the reflections of objects from polished planes, and the inverse practice of *perspective*.

His Linear *Perspective* was first published in 1715; and his New Principles of Linear *Perspective* in 1719, which he intended as an explanation of his first treatise. In 1738, Mr. Hamilton published his Stereography, in 2 vols. fol. after the manner of Dr. Taylor. But the most complete system of *perspective*, both as to theory and practice, on the same principles, is that of Mr. Kirby, the third edition of which was published in 1768, fol. We have also treatises on this subject, by the Jesuit, originally written in French, at Paris, translated by Mr. Chambers, and printed at London, in 1726, Highmore, Ware, Cowley, Priestley, Ferguson, &c.

The instruments necessary for drawing according to the rules of *perspective* are a DOUBLE SQUARE, a PARALLEL *ruler*, a drawing board (which is only a smooth board made exactly square), a SECTOR, a REFRACTOR; to which may be added a drawing pen, and a black-lead pencil.

But to return to the doctrine of linear *perspective*. Suppose a glass-plane H I, (*Tab. Perspect. fig. 3.*) raised perpendicularly on a horizontal plane: and the spectator S, directing his eye O, to the triangle A B C: if now we conceive the rays A O, O B, O C, &c. in their passage through the plane, to leave their traces or vestigia in *a*, *b*, *c*, &c. on the plane; there will appear the triangle *a b c*, which as it strikes the eye by the same rays *a* O, *b* O, *c* O, by which the reflected particles of light from the triangle A B C are transmitted to the same; it will exhibit the true appearance of the triangle A B C, though the object should be removed, the same distance and height of the eye being preserved.

The business of *perspective*, then, is to shew by what certain rules the points *a*, *b*, *c*, &c. may be found geometrically: and hence, also, we have a mechanical method of delineating any object very accurately.

Hence it appears, that *a b c* is the section of the plane of the picture with the rays, which proceed from the original object to the eye: and, therefore, when this is parallel to the picture, its representation will not only be parallel to the original, but similar to it, though smaller in proportion, as the original object is farther from the picture. If the original is brought to coincide with the picture, the representation will be equal to the original; but as the original is removed farther and farther from the picture, the image of it will become smaller and smaller, and also rise higher and higher in the picture, till at last, when the original is supposed to be at an infinite distance, its image, or representation, will vanish into an imaginary point, exactly as high above the bottom of the picture as the eye is above the ground or original plane, upon which the spectator, the picture, and the original object are supposed to stand. This may be familiarly illustrated in the following manner: Suppose a person at a window looks through an upright pane of glass at any object beyond it; and, keeping his head steady, draws the figure of the object upon the glass, with a black-lead pencil, as if the point of the pencil touched the object itself; he would then have a true representation of the object in *perspective*, as it appears to his eye. In order to this, it is necessary, first, that the glass be laid over with strong gum-water, which, when dry, will be fit for drawing upon, and will retain the traces of the pencil; and, secondly, that he looks through a small hole in a thin plate of metal, fixed about a foot from the glass, between it and his eye, and that he keeps his eye close to the hole, otherwise he might shift the position of his head, and consequently make a false delineation of the object. Having traced out the figure of the object, he may go over it again, with pen and ink; and, when that is dry, put a sheet of paper upon it, and trace it in this with a pencil; then, taking away the paper, and laying it on a table, he may finish the picture, by giving it the colours, lights, and shades, as he sees them in the object itself; and thus he will have a true resemblance of the object. See DESCENDING.

Perspective is either employed in representing the *scenographies* and ground-plots of objects, as projected on *perspective* planes; or in *scenographies* and representations of the bodies themselves.

From this general view of *perspective*, the necessity of it in the art of painting is obvious. Accordingly Leonardo da Vinci observes, that the practice of painting ought always to be built upon a rational theory, of which *perspective* is the guide and gate; and without which it is impossible to succeed, either in designing or in any of the arts depending upon it.

In order to understand the practice of *perspective*, it will be necessary to premise some definitions, and general principles, upon which its various operations depend. Several of these occur in the course of this work, but it may be convenient and useful to give, in this place, a brief and connected view of them.

The *point of sight*, in *perspective*, is that point E (*fig. 4.*) where the spectator's eye should be placed to view the picture. The *point of sight*, in the picture, is the same with the centre of the picture, or the point directly opposite to the eye, and the nearest to it; called also the principal point.

If from the point of sight E, a line E C, be drawn perpendicular to the picture O *b* I; the point C, where the line intersects the picture, is called the *centre of the picture*; and E C the principal ray.

The *distance of the picture* is the length of the line E C, which is the common section of the vertical and horizontal planes; and if this distance be transferred to the horizontal line on each side of the point C, as is sometimes the case, the extremes are called the *points* of distance: for the points of distance are set off from the point of sight, sometimes on the horizontal line, and sometimes on the perpendicular E C.

As the beauty of *perspective* depends on the point of distance, the eye ought never to be placed too near the object, nor too far from it. It should never be nearer to the object than half of its largest dimension, for in this situation the visual angle will be 90°; and this is the largest angle which the eye can well discover at one cast. If it be made less than 45°, the object will be too much contracted, and the visual angle so small, that the returns in buildings would not be distinguished, and the whole would appear confused. And, therefore, when the visual angle is about 60°, or when the distance of the eye from the extremities of the object is nearly equal to its longest dimension, the object will be seen with the greatest advantage. However, in some cases, such as in painting deceptions, or for pictures with curvilineal objects, the distance should be taken as great as possible: and in drawing agreeable *perspective* views of small objects, the observer should be considered as viewing them under an angle not exceeding 30° at most.

The real object, whose representation is sought, whether it be a line, point, or plane figure, is the *original object*; and the *original plane*, called also the *geometrical plane*, is that plane upon which the real object is situated: thus the ground or bottom plane K I, is the original plane, and A B G D is the original object. The line O I, in which the ground plane cuts the bottom of the picture, is called the section of the original plane, *ground* LINE, *line of the base*, or *fundamental line*.

If an original line A B be continued, so as to intersect the picture, the point of intersection R is called the intersection of that original line, or its *intersecting point*.

The *horizontal plane* is the plane *a b d*, which passes through the eye, parallel to the horizon, and cuts the *perspective* plane or picture at right angles; and the *horizontal* line *b g* is the common intersection of the horizontal plane with the picture.

The *vertical plane* is that which passes through the eye at right angles to the ground plane, and perpendicular to the picture, as E C S N; and the *vertical line* is the common section of the vertical plane and the picture, as C N.

The *line of station* S N is the common section of the vertical plane with the ground plane, and perpendicular to the ground line O I.

The *line of the height of the eye* is a perpendicular, as E S, let fall from the eye on the ground plane. This height, which determines that of the horizontal line from the bottom of the picture, should never be so great as the distance of the eye. In EASEL-*pieces*, or moveable pictures, the height of the eye is left entirely to the direction of the artist; but it is observed in general, that

low horizons have a much better effect than high ones; for which reason the height of the horizontal line should never exceed one half of the height of the picture; and perhaps the most proper height would be one third part. However, if the picture be a fixed one, then the height of the horizontal line must be exactly level with the spectator's eye. The size of the picture is to be regulated by the distance and height of the eye.

The *vanishing line* of the original plane is that line where a plane passing through the eye, parallel to that original plane, cuts the picture: thus H *g*, *fig.* 5. is the vanishing line of A B G D. It is plain that no point in the original plane can have its image in the picture above the line H *g*, as long as the position of the picture and eye remain the same: and that if the original plane A B G D were infinitely extended beyond the picture, yet its *perspective* appearance, in this case, would be a finite space, bounded by the vanishing line H *g*. It is also plain, from this definition, that if two or more planes, A B G D and T, are parallel to each other, they will have the same vanishing line H *g*.

The *vanishing point* of the original line is that point where a line drawn from the eye, parallel to that original line, intersects the picture: thus C and *g* are the vanishing points of the lines A B, K I. Hence it follows, that the vanishing points C and *g* of the lines A B, K I, in any original plane A B G D, are in the vanishing line of that plane.

If from the point of sight a line be drawn perpendicular to any vanishing line, the point where that line intersects the vanishing line, is called the centre of that vanishing line: and the *distance of a vanishing line* is the length of the line which is drawn from the eye, perpendicular to the said line.

Measuring points are points from which any lines in the *perspective* plane are measured, by laying a ruler from them to the divisions laid down upon the ground line. The *measuring point* of all lines parallel to the ground line is either of the points of distance on the horizontal line, or point of sight. The *measuring point* of any line, perpendicular to the ground line, is in the point of distance on the horizontal line; and the *measuring point* of a line oblique to the ground line is found by extending the compasses from the vanishing point of that line to the point of distance on the perpendicular, and setting it off on the horizontal line.

Having explained the principal terms that occur in *perspective*, we shall farther premise some general propositions, from which the practical operations result:

I. *The representation a b, fig.* 6. *of a line* A B *is part of a line* S C, *which passes through the intersecting point* S, *and the vanishing point* C, *of the original line* A B. For the plane B D E N, passing through the eye E and the original line A B, will pass through the intersecting point S, and the vanishing point C, and cut the picture in the line S C. And since the visual rays A E, B E, drawn from the extremities of the line to the eye, are in the plane B D E N, and consequently their sections *a*, *b*, with the picture, are in the section S C of that plane with the picture, *a*, *b* must be the projections of A, B. But B E A is a plane of rays which form the projection *a b* of the whole line A B, and as B E A is in the plane B D E N, the section *a b* must be a part of the section S C, which passes through S and C. Hence it follows, that, whatever be the situation of any original line, its representation upon the picture will always be in that line which is drawn through its intersection and vanishing point. For let the oblique line A D, *fig.* 7. be in the plane G F E O M, whose section with the picture is V O. Continue D A to cut the picture in V, and draw its parallel E O to cut the picture in O, which will be the vanishing point of A D. From the extremes of the line A D produce the rays A E, D E, to the eye E, and *a d*, the image of A D, in part of the line V O, which passes through the intersecting point V, and the vanishing point O.

II. *If the original plane is parallel to the picture, it can have no vanishing line upon it; consequently the representation will be parallel*; because a parallel plane, that passes through the eye, can never cut the picture, and consequently can produce no vanishing line upon it. Nor can lines parallel to the picture have any vanishing points upon it; but their images will be parallel to the originals. If the original is perpendicular to the ground line, as A B, *fig.* 6. then its vanishing point will be in C, the centre of the picture, or point of sight; because E C is perpendicular to the picture, and, therefore, parallel to A B. All lines, which are parallel to each other, but not parallel to the picture, will have the same vanishing point; because a line which passes through the eye, being parallel to one of them, is parallel to all the rest; and, therefore, they can have but one vanishing point, whatever be their number.

III. *The image of a line bears a certain proportion to its original.* In this proposition there are three cases; for the original line may be perpendicular, parallel, or oblique to the plane of the picture. In the first case, let A B, *fig.* 8. be the original line, consisting of three equal parts, of which E C contains two; then E C + A B = B S = five parts. Divide A C into five equal parts, and the ray B E will pass through *b*; and A *b* : A C :: B A : B A + C E (= B S), i. e. the image is to the distance between the vanishing point C and the intersecting point A, as the original object is to its own length added to the distance of the eye from the picture. See Simpson's Geometry, th. 12 book vii. Hence it follows, that A C − A *b* = C *b* : A B + C E − A B = C E :: A C : A B + C E, or C *b* : A C :: C E : A B + C E, i. e. the distance between the vanishing point of a line and any point *b* in its image is to the distance between the vanishing point and the intersecting point as the distance E C is to A B + C E. From a view of the figure it is also evident, that A *b* : E S :: A B : B S, i. e. the height of the point *b* in the picture is to the height of the eye as the distance of the objective point from the picture is to the sum of the same distance and that of the eye from the picture.

In the second case, when the original line is parallel to the plane of the picture, the image *a b* of a line A B, *fig.* 9. parallel to the picture is to its original A B as the distance E C of the image is to the distance E D of the original line. Suppose the figure constructed, and it is plain, that the triangles E B D, E C *b*, and E C *a*, E D *a*, are respectively equiangular, because *a b* is parallel to A B: and, therefore, C *b* : D B :: E C : D E, and C *a* : D A :: E C : D E; consequently *a b* : A B :: E C : E D. In the third case, when the original line is oblique to the picture, the image A *b* of the oblique line A B, *fig.* 10. is to the distance A V between its vanishing point V, and intersecting point A, as the length of the line A B is to the sum of A B and E V, the distance of the vanishing point V from the eye. The lines A B and E V are parallel by construction; therefore the triangles E V *b* and A B *b* are equiangular; therefore, V E : A *b* :: E V : A B, i. e. the distance between the vanishing point of an oblique line and any point of its image is to the remaining part of A V as the distance of the vanishing point is to the original line: and A *b* : A *b* + *b* V = A V : A B : A B + E V.

IV. *The image of a line may be determined by transferring the length or distance of the given line to the intersecting line; and the distance of the vanishing point to the horizontal line*; i. e. *by bringing both into the plane of the picture.* Let A B be the original line, whose vanishing point is V, and produce the ground line F A, and the vanishing line H V, and draw A V. From the intersecting point A transfer the line A B to D, and from V transfer E V to *b*, then draw the lines B E and D *b*, which will both pass through the same point *b*, and give A *b* for the image of A B. See Simpson's Geom. book vii. th. 12. cor.

Having premised the general principles of *perspective*, we shall now subjoin some examples of the practice of *lineographic perspective* in the following problems.

I. *To find the representation of an objective point* A.—From A, *fig.* 11. draw any line at pleasure, as A 1, intersecting the bottom of the picture in 1; and from the eye E draw E H parallel to A 1, intersecting the horizontal line in H; which will be the vanishing point of A 1; draw H 1, and from A a line to E, intersecting H 1 in *a*; and *a* will be the representation of the original point A. Otherwise, draw A 1, A 2, *fig.* 12, N° 1, at pleasure, intersecting the bottom of the picture in 1 and 2; and from the eye E draw E H, parallel to A 1, and E L parallel to A 2; then draw H 1 and L 2, which will intersect each other in *a*, the representation of A.

There is also another method of resolving this problem, or of exhibiting the *perspective* appearance *b*, of an objective point H *fig.* 13.) From the given point draw H I perpendicular to the fundamental line D E. From the fundamental line D E cut off I K = I H; through the point of sight F draw a horizontal line F P; and make F P equal to the distance of the eye S L: lastly, from the point I to the point of sight F, draw F I; and from K to the point of distance P, the line P K. The intersection *b* is the appearance of the objective point. For O F is parallel to H I, therefore F is the vanishing point of H I; and since the representation of H I is in the line I F, and consequently the image of the point I is in the same line; and since O P is parallel to H K, because the triangles O F P and H I K are isosceles and right angled, and consequently equiangular; and O F being parallel to H I, F O H = O H I, therefore P O H = O H K;

=OHK; P will be the vanishing point of HK, and the image of the point H will be found somewhere in the line KP; consequently it muſt be exhibited in *b*, the common interſection of LF and KP.

Hence, 1. ſince the appearance of the extreme points of a right line being given, the appearance of the whole line is given; the *ichnographic* projection of any rectilinear figure may be had by this method. And, 2. ſince any number of points of a curve line may by this means be projected on the *perſpective* plane; the projection of curve lines may likewiſe be effected after the ſame manner. And, 3. therefore, this method will ſuffice for mixtilineal figures; and is conſequently univerſal.

II. *To find the repreſentation of a line* A B (*fig.* 14.) *which is perpendicular to the ground line of the picture.* The point C, where E C interſects the horizontal line, is the vaniſhing point of A B; and, therefore, if A C be drawn, and from B be drawn B E, interſecting A C in *b*; A *b* will be the image of A B.

Otherwiſe; from B, *fig.* 15. draw B 1 at pleaſure, interſecting the ground line in 1; and from the eye E draw E H parallel to B 1, interſecting the horizontal line in H; then H is the vaniſhing point of B 1; and, therefore, drawing A C and 1 H, the point *b* of their interſection will determine the required image A *b*.

III. *To determine the image of a line* A B *parallel to the ground line.* Draw A 1, B 2 (*fig.* 16.) perpendicular to the ground line, and C will be the vaniſhing point of thoſe lines; draw 1 C, 2 C, and B E interſecting 2 C in *b*; then draw *a b* parallel to H L, and it will be the image of A B.

Otherwiſe, by two vaniſhing points: draw A 2 (*fig.* 17.) at pleaſure, interſecting the ground line in 2, and draw E H parallel to A 2, then H is the vaniſhing point of A 2: draw 2 H interſecting 1 C in *a*; and the parallel line *a b* will be the image required.

IV. *To exhibit the image of a line* A B *oblique to the picture.* Produce A B (*fig.* 18.) to the picture, and draw E H parallel to it; from 1 draw 1 H, and from the extremities A and B draw lines to E, which will interſect 1 H in *a* and *b*; and *a b* is the image of A B.

Otherwiſe; from A, B (*Tab.* II. *Perſpect. fig.* 22.) draw A 1, B 1, parallel to each other: and from E draw E L parallel to A 1, B 1; then draw 1 L, 1 L interſecting 2 H in *a* and *b*, and *a b* is the repreſentation of A B.

The problems now laid down will ſerve for determining the ſituation of all objects that are ſuppoſed to lie upon the ground.

V. *To find the* perſpective *appearances of a triangle*, A B C, (*fig.* 23.) *whoſe baſe* A B *is parallel to the fundamental line* D E. To the fundamental line D E draw a parallel at an interval equal to the altitude of the eye. Aſſume a fundamental point V, oppoſite to this either directly or obliquely, as the caſe requires. Tranſfer the diſtance of the eye from V to K. From the ſeveral angles of the triangles A C B, let fall perpendiculars, A 1, C 2, B 3: ſet off theſe perpendiculars upon the fundamental line D E oppoſite to the point of diſtance K. From 1, 2, 3, draw right lines to the fundamental or principal point V 1, V 2, V 3. From the points A, B, and C, of the fundamental line D E draw other right lines A K, B K, C K, to the point of diſtance K.

Since *a*, *b* and *c* are the appearances of the points A, B and C; the right lines *c a*, *a b*, *b c*, being drawn, *a c b* will be the appearance of the triangle A C B.

After the ſame manner is a triangle projected on a plane, where the vertex C is oppoſed to the eye: all here required is, that its ſituation on the geometrical plane be changed, and the vertex C be turned towards the fundamental line D E.

Otherwiſe; produce D A and D B (*fig.* 24.) to the ground line, and draw E L parallel to A D, and E H parallel to B D; then draw 1 L and 2 H interſecting each other in *d*; and if we be repreſentation of the angular point D. From B draw B 1 parallel to A 1, and L will be its vaniſhing point: therefore, draw 1 L interſecting 2 H in the point *b*, and *b* will be the repreſentation of the angular point B; and ſince A B is parallel to the bottom of the picture, from the point *b* draw *b a* parallel to the ground line, and the image of the triangle will be completed: or, it may be done by drawing A 3 perpendicular to the bottom of the picture, and then 3 C cutting 1 L in the point *a*, &c. If this triangle be equilateral, it may be eaſily divided into two equal parts, by deſcribing from E, with any radius, one arc O P, biſecting it in X, and drawing E C; from C draw a line through *d*, interſecting *a b* in *e*. This is evident, becauſe C is the vaniſhing point of D F.

The triangle may be alſo projected by having only one ſide *a d* (*fig.* 25.) given: let this be produced to its vaniſhing point L, and draw L E; then at L, with the diſtance L E, deſcribe the arc H E, interſecting the horizontal line in H, and H is the vaniſhing point of the other ſide *b d*; and by drawing *a b* parallel to the horizontal line, the repreſentation will be completed.

This method furniſhes a very uſeful rule for ſhortening the operations in *perſpective*. For ſuppoſe *a* L to be a line given in *perſpective* (that is, to be drawn upon the picture) to any vaniſhing point L; and let it be required to cut off a part *a d*, of the line *a* L, to repreſent a given length. From the end *a* of the line *a d*, draw *a b* parallel to the horizontal line H L, and call *a b* the repreſentation of a parallel line upon the picture; then from L the vaniſhing point of *a d* tranſfer the diſtance L E to H: from H draw a line to *b*, interſecting *a* L in *d*, then will *a d* repreſent the length of the line *a b*. Or, if *a d* be a line given in *perſpective*, and it be required to find the length of the parallel line *a b*, the ſame proceſs will ſerve: for a line, drawn from H through *d*, will cut off *a b* to repreſent a length (in *perſpective*) equal to *a d*; becauſe, the whole figure *a b d*, being the repreſentation of an equilateral triangle, its ſides are all equal in the original figure; conſequently, in either of the above caſes, *a b* and *a d* muſt repreſent lines which are equal to each other.

VI. *To exhibit the* perſpective *appearance of a ſquare* A B D C (*fig.* 26.) *ſeen obliquely, and having one of its ſides* A B *in the fundamental line.* The ſquare being viewed obliquely, aſſume the principal point V in the horizontal line H K, in ſuch manner as that a perpendicular to the fundamental line may fall without the ſide of the ſquare A B; at leaſt may not biſect it: and make V K the diſtance of the eye. Tranſfer the perpendiculars A C and B D to the fundamental line D E; and draw the right lines K B, K D, as alſo A V, V C. Then will A and B be their own appearances; and *c* and *d* the appearances of the points C and D. Conſequently A *c d* B is the appearance of the ſquare A B D C. If the ſquare A C B D ſhould be at a diſtance from the fundamental line D E; which yet rarely happens in practice; the diſtances of the angles A and B muſt likewiſe be tranſferred to the fundamental line: as is evident from the preceding problem. And ſince, even the oblique view is not very common; in what follows, we ſhall always ſuppoſe the figure to be poſited directly oppoſite to the eye: unleſs where the contrary is expreſly mentioned. Thus: let the original ſquare be A B F D. (*fig.* 27.) Draw A C, B C to the vaniſhing point C of the perpendicular ſides A D, B F; from the eye E draw E H and E L parallel to the diagonals B D and A F: then from A and B draw lines to L and H, interſecting A C in *d*, and B C in *f*; then *d f*, being drawn, completes the repreſentation.

Having found the image of one ſquare, that of any other, *i k m n*, may be eaſily found, by ſuppoſing *i k* to be one ſide of the image, and drawing, from *i* and *k*, *i* C and *k* C; then from *i* draw *i* H, and from *k* draw *k* L, which will give the depth of the ſquare.

Or, one diagonal only will be ſufficient. Thus: A L interſects B C in *f*; therefore, draw *f d* parallel to the horizontal line.

With reſpect to ſquares thus ſituated we may obſerve, that the vaniſhing points H and L of their diagonal, are exactly as far from the centre of the picture, or point of ſight, as from the eye. For H C and L C are each equal to the diſtance C E; and, therefore, by ſetting off C H or C L equal to C E, the lines E H and E L may be omitted.

There are other methods of reſolving this problem: thus (in *fig.* 28.) if only the height A B of the ſquare be given; ſet off A D and A 1 equal to A B; from A and D draw lines to C, and make C L = C E; draw 1 L, interſecting A C in *b*; then will A *b* be equal to A 1; draw *b d* parallel to the horizontal line, and the repreſentation will be completed. Or, if one ſide G I be given, draw lines from G and I to C; make C H = C E; from H draw H G, interſecting I C in *r*; and draw the parallel *r s*. Or, if the middle diameter *n p* be given, biſect *n p* in *e*; from C draw lines through the extremes *n*, *p*; from H produce a line through *e*, interſecting I C in *r*, and G C in G; laſtly, from *r* and G draw the parallels G I, *r s*, which complete the figure.

VII. *To exhibit the appearance of a ſquare* A B C D (*fig.* 29.) *whoſe diagonal* A C *is perpendicular to the fundamental line.* Continue the ſides D C and C B till they meet the fundamental line in 1 and 2. From the principal point V ſet off the diſtance of the eye to K and L. From K to A and 1 draw right lines K A and K 1; and from L to A and 2, the right lines L A, L 2. The interſections of theſe lines will exhibit the appearance of the ſquare A B C D viewed angle-wiſe.

VIII. *To exhibit the appearance of a ſquare* A B C D (*fig.* 30.) wherein another, I M G H, is inſcribed; the ſide of the greater, A B, being in the fundamental line; and

the diagonal of the leſs, perpendicular to the fundamental. From the principal point V, ſet off, each way, on the horizontal line HB, the diſtances VI. and VK; draw VA and VB; and KA and LB; then will *AedB* be the appearance of the ſquare ACDB. Produce the ſide of the inſcribed ſquare IH, till it meets the fundamental line in *i*; and draw the right lines K 1, and KM; then will *ibg*M be the repreſentation of the inſcribed ſquare IHGM. Hence, is eaſily conceived the projection of any figures inſcribed in others.

IX. *To exhibit the* PERSPECTIVE *of a pavement, conſiſting of ſquare ſtones, viewed directly.* Divide the ſide AB *fig.* 31, tranſverſed to the fundamental line DE into as many equal parts as there are ſquare ſtones in one row. From the ſeveral points of diviſion, draw right lines to the principal point V; and from A to the point of diſtance K, draw a right line AK; and from B to the other point of diſtance L, draw another LB. Through the points of the interſections of the correſponding lines draw right lines on each ſide, to be produced to the right lines AV and BV. Then will A *fg* B be the appearance of the pavement AFGB.

X. *To determine the repreſentation of a regular hexagon* ABDFGI, *(fig.* 32.) *when one of its ſides is parallel to the ground line.* Produce the ſeveral oblique ſides to interſect the ground line, and parallel to theſe draw EH and EL; then H will be the vaniſhing point of AI and DF, and L will be the vaniſhing point of of BD and IG. Through the angular points A, F, B, and G, draw F 1, G 2, which, being parallel to the ſides BD and AI, will have L and H for their vaniſhing points: from 1 draw 1 L, and from 2, draw 2 H, interſecting each other in *i*, then *i* will be the repreſentation of the corner I. From 1 draw 1 L, interſecting 2 H in *a*; and *a* will be the repreſentation of the corner A, and *a i* that of the ſide AI; then draw 1 L and 2 H, and *b* will be the repreſentation of B, and *a b*, being drawn, will be the image of AB, &c. In the ſame manner the image of an octagon may be determined. This method will likewiſe ſerve for the repreſentation of a circle; for having found eight points in the circumference, they will be ſufficient guides for drawing the figure. This problem may be reſolved by only having one ſide *b d (fig.* 33) in the repreſentation given. Through the corner *b* draw a line *a n* parallel to to the horizontal line; and produce *b d* to its vaniſhing point H; from H draw HE, and make HL=HE; then from L, draw a line through *d*, interſecting *a n* in *n*; then *b n* repreſents a line equal to the original of *b d*; make *ab*=*bn*; and *a b* is the repreſentation of one parallel ſide; from *d* draw *d* L, and from *a* draw *a* H, cutting *d* L in *f*; then *f* is another corner; and *d f* repreſents another ſide. Again, from *d* draw *di* parallel to the horizontal line, and *a* L cutting it in *i*; and *i* is another corner, and *a i* another ſide: laſtly, draw H*i* and the parallel *f g*, and the repreſentation is completed.

XI. *To exhibit the* PERSPECTIVE *of a circle.* If the circle be ſmall, circumſcribe a ſquare about it. Draw diagonals and diameters *ba* and *de (fig.* 34.) interſecting each other at right angles; and draw the right lines *f g* and *h c* parallel to the diameter *de* through *b* and *f*; as alſo through *a* and *g* draw right lines meeting the fundamental line DE in the points 3 and 4. To the principal point V draw right lines V 1, V 3, V 4, V 2; and to the points of diſtance L and K, draw the right lines L 2 and K 1. Laſtly, connect the points of interſection, *a*, *b*, *d*, *f*, *h*, *g*, *c*, *e*, with arcs *a b*, *b d*, *d f*, &c. Thus will *ab d f hgeca*, be the appearance of the circle.

If the circle be large, on the middle of the fundamental AB *(fig.* 35.) deſcribe a ſemicircle; and from the ſeveral points of the periphery, C, F, G, H, I, &c. to the fundamental line, let fall perpendiculars C 1, F 2, G 3, H 4, I 5, &c. From the points A, 1, 2, 3, 4, 5, &c. draw right lines to the principal point V, as alſo a right line from B to the point of diſtance L; and another from A to the point of diſtance K. Through the common interſections draw right lines as in the preceding problem; thus ſhall we have the points *c*, *f*, *g*, *h*, *i*, which are the repreſentations of C, F, G, H, I; and theſe, being connected as before, give the projection of the circle.

The eaſieſt and beſt method for putting a circle into *perſpective* ſeems to be the following; which admits alſo of univerſal application. Let *a b (fig.* 36.) repreſent the diameter of the given circle: biſect it in *c* for the centre; make CH, CL, each equal to UW the breadth of the picture; divide CH, CL, each into five equal parts; and make C*k*, C*i* each equal to two parts and one fourteenth. From H produce a line at pleaſure through the centre *c*; from *b*, draw two lines through the extremities *a*, *b*, interſecting H *i* in the points 3 and 4; do the ſame by the line L *k* with the point *k*; then draw a line from C through the centre *c*; from H draw lines through 3 and *b*, interſecting C 1 in 1 and 2; and having thus obtained eight points in the image of the circumference of a circle, the outline may be very accurately drawn through theſe points.

Hence appears, not only how any curvilinear figure may be projected on a plane; but alſo how any pavement, conſiſting of any kind of ſtones, may be delineated in *perſpective*.

Hence alſo appears what uſe the ſquare is of, in *perſpective*; for even in the ſecond caſe we uſe a ſquare divided into certain areolæ, and circumſcribed about the circle; though it be not delineated on the geometrical plane in the diagram.

XII. *To exhibit the* PERSPECTIVE *of a regular pentagon, having a broad limb, terminated by lines parallel thereto.* 1. From the ſeveral angles of the exterior pentagon A, B, C, D, E, *(fig.* 37.) to the fundamental line TS, let fall perpendiculars A 0, B 1, C 2, D 3, E 4; which, as in the former, tranſfer to the fundamental line. Connect the points 1, 2, 3, 4, to the principal point V; and the points 1, 2, 3, 4, to the point of diſtance K. Thus will the common interſections repreſent the appearance of the exterior pentagon. 2. If now, from the inner angles G, H, K, L, I, the perpendiculars G 0, H 5, K 6, L 7, I 8, be in the like manner let fall; and the reſt be done as in the former; we ſhall have the repreſentation of the inner pentagon. The pentagon ABCDE, therefore, with its limb, is repreſented in *perſpective*.

This problem is added for the ſake of an inſtance of the projection of a figure that has a broad limb, or edge.

It muſt be here obſerved, that if the magnitudes of the ſeveral parts of an object be given in numbers, together with the height and diſtance of the eye; its figure is to be firſt conſtructed by a geometrical ſcale; and the fundamental point, with the point of diſtance, to be determined by the ſame.

Nor is it always neceſſary, that the object be delineated under the fundamental line: in the projection of ſquares and pavements it is beſt let alone. But where it is neceſſary, and ſpace is wanting, draw it apart; find the diviſions in it, and tranſfer them to the fundamental line in the plane.

Threads being hung in the principal point, and the point of diſtance, and thence ſtretched to the points of the diviſions of the fundamental line; the common interſection of the threads will give the projection of the ſeveral points without confuſion; a thing much to be feared from the multiplicity of lines to be drawn.

XIII. *Having given the centre C of the picture, (fig.* 38.) *the vaniſhing line* H L, *and two vaniſhing points* H, L, *of a ſquare b d b f; to find the diſtance of the picture.* Biſect HL in A; from A with the radius AH (or AL) deſcribe the arc L E H; from C draw the perpendicular CE to touch the arch LEH, and EC will be the diſtance of the picture. For, drawing LE and HE, which will make a right angle at E, and EH, EL, are parallel to the originals of *b d*, *b f*, and conſequently CE is the true diſtance of the eye, &c.

XIV. *Having given the repreſentation of two lines* B *a*, D *f*, *(Tab.* III. *Perſpect. fig.* 39.) *to find their originals* BA, DF. From the interſecting point B, draw B A parallel to CL; from E draw a line through *a* interſecting AB in A; then BAis the original of B *a*. Again, from the vaniſhing point H, draw EH; and from the interſecting point D, draw DF parallel to EH; then from E, draw EF through the point *f*, which gives DF for the original of D *f*.

N. B. Theſe two laſt articles comprehend a part of what Dr. Taylor calls the *inverſe* practice of PERSPECTIVE.

Having in the preceding problems illuſtrated the principles and practice of *perſpective*, as it relates to objects ſituated upon the ground plane, we ſhall now give a brief account of the method of repreſenting objects, that are perpendicular and oblique to it; obſerving, in general, that thoſe which are parallel to the ground plane may be drawn by the help of thoſe that are perpendicular to it; and that lines perpendicular to the ground plane muſt be repreſented by lines perpendicular to the ground line, wherever they are ſituated. In order to determine the vaniſhing lines and vaniſhing points of planes which are perpendicular to the ground, we may ſuppoſe theſe planes to be either perpendicular to the picture, or oblique to it. Let the ſquare plane BKIF *(fig.* 40.) be perpendicular to the picture, ſo that the top and bottom of it vaniſh into C, its centre. Draw the line EV through C, and perpendicular to HL, and EV will be the vaniſhing line of the plane BKIF. And ſince CH is perpendicular to the vaniſhing line EV, C is the centre of that vaniſhing line; and as CH is equal to the diſtance of the eye, H will be the tranſpoſed place of the eye, and HC the diſtance of the vaniſhing line EV. But if the plane *a b e d (fig.* 41.) is oblique to the picture, then the top and bottom of it will not vaniſh into its centre C, but into the point L, on one ſide of the centre.

Draw

Draw a line through the vanishing point L, perpendicular to the horizontal line; then VU is the vanishing line of the plane *abcd*. And because CL is perpendicular to the vanishing line VU, L will be the centre of that vanishing line. Again, draw EL, and this will be the distance of the eye E from the vanishing line VL; and this distance transferred to H, will give H for the transposed place of the eye, and HL for the transposed distance of the vanishing line VU.

XV. *To find the representations of planes, whose bases are perpendicular to the ground line of the picture.* E. g. Let one corner A of the plane ABFD (*fig.* 42.) be at the bottom of the picture; and let it be required to draw the representation of a plane ten feet high, and four feet wide. From A, upon the ground line, make a scale of equal parts, representing feet at pleasure: from A draw AD perpendicular to this line, and produce it at pleasure: upon AD set ten feet from A upwards, and draw DC to the centre C, and from A draw AC; make CH=CE, and draw H4 intersecting AC in B; then AB=4 feet: therefore, from B draw BF parallel to AD, and ABFD will be the representation required. Let the plane, whose representation *efgh* is required, be four feet wide, and five feet high, and its nearest corner *e* be one foot from the bottom of the picture. Draw CN at pleasure; make CL=CE; and set off one foot from N to 9, and draw L9 intersecting CN in *e*; and *e* will be one foot from the bottom. Take 4 feet more, as 9 5, and draw 5L intersecting CN in *f*, and *ef* is equal to 4 feet; draw NO perpendicular to the bottom of the picture, and make it equal to 5 feet; draw *eg*, *fh*, parallel to NO, and draw OC, which will complete the proposed representation. Otherwise: from *e* draw *ew* parallel to NA, intersecting L 5 in *w*; then *ew* will be 4 feet; make *eg* to *ew* as 5 is to 4, and draw gC. In the same manner we may determine the image *abcd* of a plane, 4 feet square, removed 5 feet into the picture, and whose lower edge is in the line AC. From *a*, where CA intersects the ground line, set off 5 feet for its distance, as A 5, and 4 feet for its breadth, as 5 9; draw H 5 and H 9, intersecting AC in *a* and *b*; then *ab* is the representation of its depth; draw *ad*, *bc*, parallel to AD, and make AQ four feet; then draw QC, which completes the figure.

Ex. 2. Having B given as one angular point of a square plane, and BM for its height and breadth upon the picture; there to determine the representation of the whole plane BFIK (*fig.* 40.) From the corner B, draw the perpendicular BF, make BF=BM, and draw MI, intersecting AC in K; draw KI parallel to BF; then FC completes the figure. If the representation be determined, and it be required to find the length and breadth of the original. Produce CB to A; at A erect a perpendicular AD; from I, produce lines through B and K, intersecting the bottom of the picture in N and 2. The space 2N comprehends eight feet, and, therefore, BK represents eight feet. For the height BF, produce CF to D, and the space AD contains eight feet. N. B. The vanishing lines of planes perpendicular to the ground are perpendicular to the horizontal line, and always pass through the vanishing point of those planes: thus, the vanishing line EV passes through C; and EV is the vanishing line of the plane BFIK, as is evident by turning the figure, and considering EV as the horizontal line, H as the eye, HE as its distance, and BFIK as the representation of a square lying upon the ground; so that in this example we have the vanishing line HL of planes parallel to the ground, and also the vanishing line EV of planes perpendicular to the ground, connected together.

XVI. *To determine the representations of planes that are parallel to the picture.* E. gr. Let the plane *abcd* (*fig.* 43.) five feet wide, and eight feet high, be removed two feet from the bottom of the picture. From A and 5, draw AC and 5C; make CH=CE, and draw 7H, intersecting 5C in *b*; then 5*b* represents a length equal to 5 or 2 feet; draw *ab* parallel to the ground line, cutting AC in *a*, which will give the length of the lower side: erect the perpendiculars *ac*, *bd*; make *bd* equal to 8 feet, and draw the parallel *dc*. If the plane *ghkk* be 9 feet high, and 3 feet wide, and 6 feet from the bottom of the picture; draw a line at pleasure from C, as C 9; take 3 feet, and draw another line from B to C; from L draw L 9, intersecting BC in *e*; then *e*B represents three feet; from *e* draw the parallel *ef*, and from L produce L*f*, intersecting *e*C in g, which gives *eg* for a *perspective* length representing *ef*. Now *gf* and *f*B are the representations of two squares, whose sides are all equal in the original figures; and therefore all the sides *ef*, *eg*, &c. represent equal lines, and, consequently, *gb* represents the depth of 6 feet, and *hg* the parallel width of 3 feet. Draw the perpendiculars *hk*, *gi*; and make *gi* three times the length of *gh*; and draw *ik* parallel to *gh*.

XVII. *To find the representations of planes, that are oblique to the ground line or bottom of the picture.* Let *abdc* (*fig.* 42.) be eight feet high, eight feet wide, and two feet from the bottom of the picture; let L be its vanishing point, and AL the line in which the plane is to stand. Draw AB perpendicular to the bottom of the picture; set 8 feet upon it, and draw B1, transferring LE to H; take A 1=2 feet, and from 1 produce 2 H, intersecting AL in *a*; then A*a* represents a line equal to A 2=2 feet. Again, from 2 feet set off 8 feet, and draw DH intersecting AL in *b*; then *ab* represents the length of 8 feet; draw *ac* and *bd* parallel to AB. When the representation is not to be of any particular dimension, the operation is exceeding simple. Let AB (*fig.* 42.) be one side given, and AD its height; from *a* and B draw AD, BF, perpendicular to the bottom of the picture; and from C draw CE. N. B. The vanishing point C of the line *AB* is the vanishing point of every line Q*q*, *mk*, &c. parallel to AB. For the application of these operations in determining the *perspective* of solid figures, see SCENOGRAPHY.

As to objects that are inclined to the ground, such as pediments, roofs of houses, &c. it is proper to observe, that this part of *perspective* was little, if at all, understood by any authors before Dr. Taylor; who has shewn, that inclined objects have their proper vanishing lines and points, as well as those which lie flat upon the ground, or are perpendicular to it; and that the method for determining the appearance of objects in either case is exactly the same. For the illustration of this method, let *adgf* (*fig.* 44.) represent the body of a house; the side *cigf* being parallel, the other side *adei* both its vanishing line VU, which passes through the centre of the picture, and is perpendicular to the horizontal line; and it is evident, that the roof is formed by two inclined planes, one leaning towards the eye, the other from it. These inclined planes have their proper vanishing lines and vanishing points upon the picture, as well as those which are either parallel or perpendicular to the ground. It has been already shewn (see *fig.* 40.) that VE, continued, is the vanishing line of all the lines, which can be drawn within the plane *adei*: however, let us here turn the figure, and call C the centre of the picture, CE the distance of the eye, and VU the horizontal line; *adei* the representation of a parallelogram, and *abi* a triangle joined to the end of it. Let us next suppose the line *fr* to be the bottom of the square *fihr*, whose vanishing point is V, and the vanishing points of its diagonals are D and F; and let *cifg* represent a parallelogram even with the eye, which will complete the representation of a solid body, like the model of a house, laid upon that side, which by workmen is called the gable end. If this be a true representation, that is, if VU be the vanishing line of *abicd*, and DF the vanishing line of *fihr*, then turning the figure in any position cannot make any alteration in the *perspective*, because VU and DF will be invariably the vanishing lines of *abicd*, *hifr*, &c. The planes *abi*, *hrfi*, are joined by the line *ib*, the vanishing point of which is V; and because the original of *fr* is parallel to the original of *ib*, both *ib* and *fr* will vanish into the same point V; or into that point where the vanishing lines VU and DF cross each other; for the vanishing point V must be in the line VU, which is the vanishing line of the plane *adeib*, and it must be also in the vanishing line DF of the inclined plane *hfi*; for the line *ib* is the common section of both planes; therefore its vanishing point must be the intersection of the vanishing line of those planes.

XVIII. *To find the vanishing line of the inclined plane hifr; and also the centre and distance of it.* Let EL be the horizontal line; C the centre of the picture, CE its distance, *adgf* the body of a house, and UV the vanishing line of its side *adei*. Upon the horizontal line, or parallel to it, draw *vs*, then the figure *vsomn* will be a small module of the perpendicular plane *adeib*; or, in other words, let *om* be the inclination of the inclined plane with *mn*, supposed to be 45°. From the eye E draw EV parallel to *ms*, intersecting the vanishing line VU in V; through V draw DF parallel to the horizontal line EL; then is DF the vanishing line required, V its centre, and EV its distance. In order to find the representation of the plane *hifr*, supposing it to be a perfect square, &c. let *ib* be the representation of one side of the square, whose vanishing point is V. Produce the perpendicular CV at pleasure; make VD, VK, VF, each equal to the distance EV of the vanishing line DF; then is VK the distance EV, transposed to K; and because VD, VF, are each equal to VK; therefore D and F are the vanishing points of the

diagonals *ir* and *fb*. From the points *i* and *b* draw *if*, *br*, parallel to the vanishing line DF; from D draw *Dr* cutting *br* in *r*; then *rb* is cut off to represent another side of the square; from V draw a line through *r*, interfecting *if* in *f*, which completes the *perspective* of a square in this position. This may alſo be done by merely giving the inclination of the plane: ſuppoſe it 45° as at the eye E make an angle with the line EC of 45°, and draw EV interſecting UV in V; make VF, VD, each equal to VE; then V is the vaniſhing point of the ſides *ib*, *fr*; and D, F, the vaniſhing points of the diagonals; from whence the figure may be completed as before. The vaniſhing line, its centre, and the diſtance of the oppoſite inclined plane, are determined in the ſame manner

XIX. *To find the vaniſhing line of a roof ibrf, &c. (fig. 45.) when the gable end abi is parallel to the picture, and to determine the whole repreſentation.* Having drawn the body of the building *ag*, and alſo the gable end *abi*; obſerving that the interior part, *if*, of the roof vaniſhes into C, the centre of the picture, and conſequently the upper part *br* will vaniſh into the ſame point, both being ſuppoſed parallel in the original figure; draw *bC*, and from *f* the line *fr* parallel to *ib*, which completes the ſide of the roof *ibrf*, without the vaniſhing line propoſed. But ſince the roof *ibrf* has an inclination with reſpect to the picture, in order to determine its proper vaniſhing line, through the vaniſhing point C draw FD parallel to *ib* or *rf*; then FD is the vaniſhing line of the inclined plane *ibrf*. From C, the centre of the vaniſhing line FD, produce CK perpendicular to FD; make CK = CE, the diſtance of the eye; and CK is the diſtance of the vaniſhing line FD, and K the tranſpoſed place of the eye. E. gr. Having given *ib* for one ſide of a ſquare roof, and found its vaniſhing line FD, and its diſtance CK, to complete the repreſentation of the roof. Make CF, CD, each equal to the diſtance of the eye CK; then F and D are the vaniſhing points of the diagonals of a ſquare. From *i* and *b* produce lines to C; and from the ſame points draw lines to F and D, interſecting *b*C, *i*C, in *r* and *f*; draw *rf*, which will be parallel to *ib*, and complete the repreſentation required.

XX. *Having given the vaniſhing line of any inclined plane, and one vaniſhing point of that plane, together with the centre and diſtance of the picture, to determine the vaniſhing line of another plane, making a given angle with the plane, whoſe vaniſhing line is* VL. Let VL, (*fig.* 46.) be the vaniſhing line of any inclined plane, V one vaniſhing point, C the center, CE the diſtance of the picture, and *abi* the angle of inclination of the two original planes; if this be a right angle, from V draw a line through C, as VD; make CI perpendicular to VD, and CI = CE; draw VI, and at I make VI*r* = *abi*, the given angle, and draw I*s* interſecting VD in *s*; through *s* draw LU parallel to IC, interſecting VI in L, and UL is the vaniſhing line required. If the plane, whoſe vaniſhing line is VU, were inclined at an angle of 60°, and it were required to find its vaniſhing line; through the centre of the picture draw VD, and find the vaniſhing line LU of a plane perpendicular to that plane whoſe vaniſhing line is VU; produce CD, and make *c*D = IC, the diſtance of LU; draw DU, which makes an angle at D of 60°, and draw DP; laſtly, draw PV, which is the vaniſhing line required. In order to find the centre and diſtance of the vaniſhing line UL; from C draw CD perpendicular to UL, and CI perpendicular to CD, and make CI = CE, and CI is the diſtance of UL; make *c*D = *c*I, which is the diſtance to be uſed for determining the repreſentations of any planes that vaniſh into the line UL. Suppoſe L the vaniſhing-point of one ſide of a ſquare, draw DU at right angles with DL, and U will be the other vaniſhing point of the ſaid ſquare. For the farther illuſtration and application of theſe rules, we muſt refer to Mr. Kirby's comprehenſive work, entitled, Dr. Brook Taylor's Method of *Perſpective* made eaſy, &c. 3d edit. 1768.

XXI. *To fix points in* perſpective *lines, or to divide theſe lines ſo as to intercept any lengths that may be required in them.* Lines parallel to the ground line may be divided, by diſtiding the ground line, and either laying a ruler from theſe diviſions to the point of diſtance in the horizon, or drawing lines to them from the point of ſight D. Lines perpendicular to the ground line are diviſible, by ſetting off diviſions from the place where they meet the ground line, and drawing other lines from them to the point of diſtance. Lines oblique to the ground line may be divided, by ſetting off on the ground line any number of diviſions from the point where the line to be divided interſects it; as from C to *k* (*fig.* 47.); taking the diſtance from the vaniſhing point *v* of the line to the point of diſtance E in the perpendicular DE, and ſetting it off along the horizontal line to *y*; and from the point thus determined, drawing a line *yb* to the point in the ground line bounding the number of diviſions: this line will interſect C*i*, the repreſentation of the given oblique line in *b*, the point required. See articles XV. XVI. XVII. above.

If a ſingle point in a given ſituation upon the ground plane be required, its place in the *perſpective* plane may be found by ſuppoſing it to be the interſection of two lines, the ſituation of which is given: as by ſuppoſing one of them to be drawn through it perpendicular to the ground line, and the other to be a line drawn from the point of diſtance, and interſecting it at a given diſtance from the ground line: or, it might be found by drawing lines making any given angle with the perpendicular, and interſecting them at proper diſtances from the ground line. To divide lines, not lying in the ground plane, but perpendicular to it, let *ac* (*fig.* 48.) be the image of a line perpendicular to the ground plane, and let a number of diviſions, e. gr. five, be cut off from the point *a*. Take at pleaſure (generally beyond the bounds of the picture) any point *e* in the horizontal line; from thence draw a line *ed* to any point *d* in the ground line; ſet off five diviſions from *e* to *f* in the perpendicular *eh*, and draw the line *fa*; draw a line from the foot *a* of the object, parallel to the ground line, interſecting *de* in *g*; and raiſing a perpendicular from *i* to *df*, find *h*, and the line *ih* contains the five meaſures required, which are to be ſet off from *a* to *b* in the given line *ac*; and thus *ab* will be equal to *fe*. The lines *de* and *eh* will ſerve to meaſure any other lines perpendicular to the ground plane, always drawing a line parallel to the ground line from the foot of the object to be meaſured to the line *ac*, and proceeding as above. It is evident, that any row of objects of the ſame height, ſtanding upon the ground plane, on a line perpendicular, or oblique to the ground line, muſt appear to diminiſh, till they vaniſh in the horizontal line; conſequently, the triangle *dfe* will contain in it perpendicular lines equal to the apparent heights of all objects that are of the height of *fe*; and this will be the caſe wherever the point *d* is taken in the horizontal line; for it will be invariably *ih* : *ef* (:: *dh* : *de* :: *dm* : *dl*) :: H*a* : H*l*.

To meaſure a line oblique to the ground plane: let the line be C*g* (*fig.* 47.) and let eight diviſions be cut off from C. For this purpoſe draw CN parallel to *gy*, and CN being conſidered as a new ground line, ſet off the given number of diviſions from C to *n*; join *a* and *y* with a line interſecting the given line in *x*; and C*x* will be the part required: or, from the vaniſhing point *g* of the given line C*g*, take *gy* parallel to the ground line AB, and equal to *gy* on the ground line ſet off the given length from C to *a*, and a line joining *a* and *y* will cut off the required part C*x*. In the firſt method, the triangles *kgy*, *k*C*a*, are ſimilar; whence *gk* : *k*C :: *gy* : C*a*; but *gy* is equal to *ga*, the diſtance of the eye from the vaniſhing point *g*, and C*a* is equal to the given oblique line by conſtruction: therefore the extreme point of it will be repreſented by *k*. See Propoſition III. above. In the ſecond method, ſince *gy* is drawn parallel to C*a*, we have *gk* : *k*C :: *gy* : C*a*; but *gy* and C*a* are equal to *gy* and C*a*, and conſequently equal to *ga*, and the given oblique line reſpectively. If the line C*g* does not ſtand upon the ground line, but is an indefinite line ſtanding on the ground plane at C (*fig.* 49.) and it is propoſed to cut off a part of it from C, equal, e. gr. to ten diviſions; find the point *y* as above; from C, parallel to the ground line, draw C*b*, from which cut off (art. 21.) a part C*a*, equal to ten diviſions, and a line joining *y* and *a* will cut the given line C*g* in *k*, the point ſought. If ſeveral other diviſions in C*g* be required, make C*b* equal to the abſolute length of ten diviſions, and through *k* draw *bk* cutting *gy* produced in *d*; and *d* will be a meaſuring point for the line C*g*; ſo that the diviſions themſelves may be ſet upon C*b* at once, and lines drawn from thence to *d* will cut the given line C*g* in the deſired points. The point *d* may be found at once, by taking *gd* to *gy* as the height of the eye is to the perpendicular CL.

In the foregoing explication of the theory and practice of *perſpective*, regard has been merely had to the appearance of objects upon an upright picture, which is generally choſen for *perſpective* repreſentations; but there are ſome caſes in which the ſituation of the picture is parallel or inclined to the ground, ſuch as ceilings, inclined walls, &c. The repreſentation of objects upon ſuch kind of ſurfaces is deducible from the ſame principles, and determined after the ſame manner. The rules for drawing the appearance of objects upon the parallel picture are exactly the ſame as thoſe for drawing the appearance of objects upon the perpendicular picture; obſerving, that

that those objects, which in the parallel picture are to be represented as erect, must be determined as those which lie flat upon the ground in the perpendicular picture; those which are parallel in one picture as those which are parallel in the other; and those which are oblique, after the same manner: or more generally, however original planes are situated, the vanishing lines of those planes must always be determined by imagining a plane to pass through the eye parallel to those planes, &c. for by this means all their representations may be projected. The inclined picture is seldom used; but those who wish to acquaint themselves with this kind of *perspective*, may find ample information in Mr. Kirby's elaborate work, already cited, and much used in the compilation of this article.

PERSPECTIVE *of building*, &c. In the practice hereof, great regard is had to the height of the horizontal line; all above the horizontal being seen in the upper part, and all below it in the under part; whence *perspective* becomes divided into the *high* and *low sight*; both which may be illustrated by what follows.

To represent a building (v. gr. palace, college, &c.) *in* PERSPECTIVE.

1. Take the ichnography, or ground-plat of the building; its lengths, breadths, and depths, by actual measuring; and take its altitude with a quadrant.

2. Make a scale divided into two or three hundred equal parts; either actually, or so as that each division signify ten parts: by this scale lay down the ground-plat; as in *fig.* 30.

This done, having a long rule, and a square, which by sliding on the rule helps you to draw your perpendiculars either, reduce it into *perspective*, in its iconographic appearance.

Then having drawn a line towards the bottom of the paper for the front or base line, as F (*fig.* 31.) divide it into as many equal parts as you find the building has in the ichnography, or more, if you please: this will serve for a scale to determine the several heights, &c. and to those divisions, with a black lead pencil, draw lines from the centre, when you have chosen it; which choice requires judgment on two accounts.

3. For if the centre be too nigh the front-line, then the depth of the whole building will be fore-shortened too much; and if too far off, it will not be fore-shortened enough. This may be illustrated thus: set an open tankard, or the like, on a stand, so as that it be a little lower than your eye; if you be at a great distance from it, you can see very little or nothing into it; if you come nigher to it by degrees, you will perceive the farther edge seem to be raised a little higher than that next you, so that you may see a little way into it; if you come very nigh it, you see too deep into it, or more than can be well expressed in picture. We shall therefore find some one place, which we must conclude the most convenient for the draught, and which may be in general determined to be as far off the front-line as the front-line is long: this rule, though it has just grounds, yet we sometimes dispense with *pro re nata*, that we may express things with the better appearance.

4. Consider how to place this centre with such advantage as that you may express those things most, which are chiefly designed; for as to the bottom and top lines of the sides of the building that run from us in or nigh the direct line to the centre, though you see the upper part very well, yet the sides that fall between the ground-line and top fall so very near one another, that it would be very difficult to express particulars in them; so that the centre must be well chosen in reference to this.

Those buildings, therefore, which you would see most of, must be placed as far off as you think convenient from the direct line that runs to the centre; and the farther they are, the plainer they will be.

Place then those things you would see least of, nighest the direct line; and see whether the others fall according to your mind; but this must be done after you have drawn your diagonal, which is the next thing.

5. Having pitched on your centre, and having from it drawn lines to every division of the front-line, you are to determine your diagonal, AR, thus: having, with a pair of compasses, measured the length of the front-line, take your compasses, and putting one foot in the centre, see where the other will reach in the horizon (on both sides, if you please); where it rests, from that point draw a thwart line to the left division of the front; and this will be truly drawn, or pretty nigh to the truth. That it is so, you may consider how it falls in respect of the two last centre-lines; for if where the next line from the last is intersected by the diagonal, you draw a parallel to the front between them, as at A 10, you will have a rhombus; if then all the sides be pretty equal, you may be sure you are nigh the right; but if the sides that run towards the centre be too long, then things will not be fore-shortened enough; and if the sides be not long enough, they will be fore-shortened too much.

6. After the front-line is thus divided, the centre fixed, and the diagonal placed, take the breadth of the chapel AB, which in the ichnography is shewn to be twenty parts; because this line is perpendicular, it must run toward the centre: therefore reckon twenty in the diagonal, and the rule laid parallel to the front in that point will give you a point in the centre-line, which will give the breadth of the chapel; and consequently a line drawn from A to B puts it into the ichnographic *perspective*. The length of the chapel being seventy divisions in the front-line, reckon seventy from I, parallel to the front-line, and there you will have a point at C.

The depth of the building from the chapel northward being one hundred and fifteen from the chapel, I reckon from D (where it cuts the diagonal at ten) onwards in the diagonal; and at one hundred and fifteen in the diagonal, with my rule, as before, parallel in this place in the front, I have the point Z in the central line. Its breadth being thirty, I reckon three divisions, and there is the just breadth there; and so on in every particular part.

Having placed the ichnography in *perspective*, you may then give every thing its proper height thus:

7. The height of the chapel being thirty, I reckon thirty on the front-line; and with this length, by a square applied to the front-line, I drop a perpendicular to that height; and so where the other side of the chapel is placed, having reckoned the height upon a supposed parallel, there I draw another line in that height; then joining these several heights by several lines, you have the profiles of each building.

To diversify these several lines, that they confound you not, make the ichnography, when you lay it into *perspective*, in discontinued crooked lines, the heights in pricked lines, and the tops of each building in continued lines, as the centre-lines are in the table. You will likewise find the centre, though it is not here expressed, as likewise the point of distance, by continuing the diagonal up to the supposed horizon, where it and the eye are placed.

Having done thus, your art must be employed for the particular expressions of things, by drawing and shadowing, which is the life of this half-formed figure, which we leave to the painter. It remains that we speak of the low-sight; and here, we suppose the horizontal line just the height of the eye, about five feet from the base; though it is generally placed higher, even to a third part of the height of the building, that the side building may be expressed the more gracefully.

The diagonal is best determined by dividing the last division of the base-line into five parts at G, taking four of these, sometimes the whole five, because we determined before, that the length of the front-line was the distance of the eye in the horizon from the point of distance; but here we take four, and then make this the distance in the horizon between the eye and the point of distance. You may then either graduate the plan at the several intersections of the diagonal with the centre-lines, or else suppose it so; and then raise the buildings as you will find by *perspective* enough of this sort every where to be met with.

PERSPECTIVE is also used for a kind of picture or painting, frequently seen in gardens, and at the ends of galleries; designed expressly to deceive the sight by representing the continuation of an alley, a building, landskape, or the like.

PERSPECTIVE, *aerial*, is sometimes used as a general denomination for that which more restrictedly is called AERIAL *perspective*, or the art of giving a due diminution or degradation to the strength of light, shade, and colours of objects, according to their different distances, the quantity of light which falls upon them, and the medium through which they are seen; the *chiaro scuro*, or CLAIR *obscure*, which consists in expressing the different degrees of light, shade, and colour of bodies, arising from their own shape, and the position of their parts with respect to the eye and neighbouring objects, whereby their light or colours are affected; and KEEPING, which is the observance of a due proportion in the general light and colouring of the whole picture; so that no light or colour in one part may be too bright or strong for another. A painter, who would succeed in *aerial perspective*, ought carefully to study the effects which distance, or different degrees or colours of light have on each particular original colour; to know how its hue or strength is changed in the several circumstances that occur, and to represent it accordingly. As all objects in a picture take their measures in proportion to those placed in the front, so, in *aerial perspective*, the strength of light, and the brightness of the colours of objects close to the picture, must serve as a measure, with

respect to which all the same colours at several distances must have a proportional degradation in like circumstances.

PERSPECTIVE, *alley in.* See ALLEY.

PERSPECTIVE, *architecture in.* See ARCHITECTURE.

PERSPECTIVE, *bird's eye view in*, is that which supposes the eye to be placed above any building, &c. as in the air at a considerable distance from it: this is applied in drawing the representations of fortifications, when it is necessary not only to exhibit one view as seen from the ground, but so much of the several buildings as the eye can possibly take in at one time from any situation. In order to this, we must suppose the eye to be removed a considerable height above the ground, and to be placed as it were in the air, so as to look down into the building like a bird that is flying. In representations of this kind, the higher the horizontal line is placed, the more of the fortification will be seen, and *vice versâ*.

PERSPECTIVE, *diagonal.* See OPERA *glass*.

PERSPECTIVE, *graphical.* See GRAPHICAL.

PERSPECTIVE *machine*, is a machine by which any person may delineate the true *perspective* figures of objects, without the help of the rules of this art. Mr. Ferguson has described a machine of this kind, the invention of which he ascribes to Dr. Bevis. The plane of this instrument is exhibited in *fig.* 52, and *fig.* 53. is a representation of it when made use of in drawing distant objects in *perspective*. *a b c f* fig. 52. is an oblong square board, represented by A B E F in *fig.* 53; *x* and *y* (X and Y) are two hinges on which the part *c d* (C L D) is moveable. This part consists of two arches or portions of circles *c m f* (C M L) and *d n l* (D N L) joined together at the top *f* (L) and at bottom to the cross bar *c d* (D C) to which one part of each hinge is fixed, and the other part to a flat board, half the length of the board *a b c f* (A B E F) and glued to its uppermost side. The centre of the arch *c m f* is at *g*, and the centre of the arch *d n l* is at *o*.

On the outer side of the arch *d n l* is a sliding piece *s* (much like the nut of the quadrant of altitude belonging to a common globe) which may be moved to any part of the arch between *d* and *l*: and there is such another slider *r* on the arch *c m f*, which may be set to any part between *c* and *f*. A thread *c p n* (C P N) is stretched tight from the centre *c* (C) to the slider *n* (N), and such another thread is stretched from the centre *d* (D) to the slider *s* (O); the ends of the threads being fastened to those centres and sliders.

Now it is plain, that by moving these sliders on their respective arches, the intersection *p* (P) of the threads may be brought to any point of the open space within the arches. In the groove *b* (K) is a straight sliding bar *t* (I) which may be drawn farther out, or pushed farther in at pleasure.

To the outer end of this bar I *figs.* 53.) is fixed the upright piece H Z, in which is a groove for receiving the sliding piece Q. In this slider is a small hole *r* for the eye to look through, in using the machine: and there is a long slit in H Z, to let the hole *r* be seen through when the eye is placed behind it, at any height of the hole above the level of the bar I.

In delineating a *perspective* representation, e. g. of the house, *g r s*, a great way off, place the machine on a steady table, with the end EF of the horizontal board A B E F toward the house, so that, when the Gothic-like arch D I. C is set upright, the middle part of the open space (about P) within it may be even with the house when you place your eye at Z, and look at the house through the small hole *r*. Then fix the corners of a square piece of paper with four wafers on the surface of that half of the horizontal board which is nearest the house; and all is ready for drawing.

Set the arch upright, as in the figure; which it will be when it comes to the perpendicular fide *t* of the upright piece *t t* fixed to the horizontal board behind D. Then place your eye at Z, and look through the hole *r* at any point of the house, as *g*, and move the sliders N and O till you bring the intersection of the threads at P directly between your eye and the point *g*: then put down the arch flat upon the paper on the board, as at S T, and the intersection of the threads will be at W. Mark the point W on the paper with the dot of a black lead pencil, and set the arch upright again, as before: then look through the hole *r*, and move the sliders N and O till the intersection of the threads comes between your eye and any other point of the house, as *p*: then put down the arch again to the paper, and make a pencil-mark thereon at the intersection of the threads, and draw a line from that mark to the former one at W; which line will be a true *perspective* representation of the corner *p g* of the house.

Proceed in the same manner, by bringing the intersection of the threads successively between your eye and other points of the outlines of the house, as *r*, *s*, &c. and put down the arch to mark the like points on the paper, at the intersection of the threads: then connect these points by straight lines, which will be the *perspective* outlines of the house. In like manner find points for the corners of the door and windows, top of the house, chimnies, &c. and draw the finishing lines from point to point: then shade the whole, making the lights and shades at you see them on the house itself, and you will have a true perspective figure of it. Great care must be taken, during the whole time, that the position of the machine be not thifted on the table; and to prevent such an inconvenience, the table should be very strong and steady; and the machine fixed to it, either by screws or clamps.

In the same way, a landscape, or any number of objects within the field of view through the arch, may be delineated, by finding a sufficient number of *perspective* points on the paper, and connecting them by straight or curved lines as they appear to the eye.

The arch ought to be at least a foot wide at bottom, that the eye at Z may have a large field of view through it; and the eye should then be, at least, 10½ inches from the intersection of the threads at P when the arch is set upright. For if it be nearer, the boundaries of view at the sides near the foot of the arch will subtend an angle at Z of more than sixty degrees, which will not only strain the eye, but will also cause the outermost parts of the drawing to have a disagreeable appearance. To avoid this, it will be proper to draw back the sliding bar I, till Z be 144 inches distant from P; and then the whole field of view, through the foot-wide arch, will not subtend an angle to the eye at Z of more than forty-five degrees; which will give a more easy and pleasant view, not only of all the objects themselves, but also of their representations on the paper whereon they are delineated. So that, whatever the width of the arch be, the distance of the eye from it should be in this proportion: as 12 is to the width of the arch, so is 144 to the distance of the eye (at Z) from it.

If a pane of glass, laid over with gum water, be fixed into the arch, and set upright when dry, a person who looks through the hole *r* may delineate the objects upon the glass which he sees at a distance through and beyond it, and then transfer the delineation to a paper put upon the glass. Ferguson's Perspective, chap. 3.

Mr. Kirby has also contrived and described an instrument, that will be useful in taking extensive views, &c. The ruler A B (*fig.* 54.) is nineteen inches long, and is graduated into nineteen equal parts; it has a dove-tail groove on its upper edge to receive the perpendicular ruler C, which has one end fitted to it, so as to slide very easily: this ruler is fourteen inches long, and is divided into fourteen equal parts, and upon the back side of it F is a fine drawn exactly in the middle, to which is fixed a silken line with a small plummet at the end. The ruler A B is fixed by two screws *a*, *c* to two pieces of thin brass; and these pieces of brass are fixed at the other ends by two screws *d*, *e*, to a stronger piece of brass *d e*, which goes close to the ruler A B, and has a joint at X turning upon a screw: below this joint is a piece of round brass about six inches long, which goes into a hole made in the top of the staff, and may be raised higher or lower, by means of a screw S: C D E represents part of this staff, the whole length of which is about three feet, and at the bottom is a rank screw made of iron and fixed to the staff. H I is a wire twenty-two inches long, with a screw at *b* to go into the hole *b*; the piece of brass wire, bent into the form *i k*, is fixed to the wire H I by the screw *i*; and the part *i* goes into the hole *f* in the brass-piece *b e*. The small wire K L is about twelve inches long, and fitted at K, at which place is a little hole above one-eighth of an inch in diameter; this wire K L is fitted to the holes *l*, *m*, *n*, *o*, which are made in the larger wire H I, and it may be placed higher or lower by means of a small screw. This instrument is used in the following manner: fix a paper upon a drawing board, as in *fig.* 55, and divide the paper lengthways into nineteen equal parts, and perpendicularly into fourteen equal parts; making these divisions greater or smaller according to your design. Then take the staff, and fix it strongly in the ground, by means of the screw at bottom, and at a convenient distance from the prospect which you intend to take. After this, put the instrument together as in *fig.* 56. and fix the ruler A B exactly horizontal by means of the plummet on the perpendicular ruler and the brass joint X; then fix the wire K L, so as to have the eye-hole exactly level with the horizon or equal to the height of the eye, and take care to have the greatest distance of the eye-hole from the ruler equal to the whole length of the longest ruler A B, and never less than the distance *b l*. Having thus fixed the instrument, proceed to make the drawing; look through the eye-hole, and then

then move the perpendicular ruler in the groove, till you get one edge exactly against some principal object; then will the parts upon the ruler shew how high the object is from the bottom of the ruler, i. e. from the bottom of the picture, and you will also know its apparent height; therefore transfer this to the paper in those squares which correspond with the divisions upon the rulers. For the breadth of objects, move the perpendicular ruler so as to be even with the sides of an object, and the divisions upon the lower ruler will shew their apparent breadths. After the same manner, get the places and apparent sizes of as many principal objects as are necessary for assisting you in completing the whole drawing, which may be done by this method with great exactness. When the drawing is finished, the instrument may be taken to pieces and put into a box, which may serve as a drawing board; the top M may be screwed into the staff, which will serve as a walking stick, and the stool to fit on may be made very portable; so that every part of this apparatus may be carried by one person without any inconvenience. Kirby, ubi supra, b. ii. p. 65, &c.

PERSPECTIVE, *military*, is that wherein the eye is supposed to be very remote from the table or plane. See *Bird's Eye View*, in PERSPECTIVE.

PERSPECTIVE, *plain, plane*, is a glass, or other transparent surface supposed to be placed between the eye and the object, perpendicular to the horizon, unless the contrary be expressly mentioned.

Such is the plane HI *fig.* 3., between the eye O, and the object, as B C, cutting the optic rays in *a*, *b*, *c*.

This, some call the *section*, some the *table*, others the *picture*, and others the *ghost*.

PERSPECTIVE, *scenographies*. See SCENOGRAPHY.

PERSPECTIVE *of shadows*. See SHADOW.

PERSPECTIVE, *specular*, is that which represents the objects in conical, spherical, or other mirrors, erect and clear, whereas on other planes they appear confused and irregular. See MIRROR and ANAMORPHOSIS.

PERSPICUITY, *perspicuitas*, in *Rhetoric*, is a principal excellence of style, to which all the ornaments and beauties of speech ought to give way; as it is necessary to render a discourse intelligible, and forms one of the constituent parts of ELEGANCE. *Prima est eloquentiæ virtus perspicuitas*, says Quintilian, lib. viii. cap. 2. There are three different ways in which *perspicuity* in a composition may be violated; viz. by obscurity, ambiguity, and unintelligible expression. The common sources of obscurity are some defect in the expression, arising from ellipses in language, the affectation of conciseness, or rapidity of thought in writers, or a bad choice of words; a bad arrangement of the words, so that the construction is not sufficiently clear; the use of the same word in different senses in the same sentence; an uncertain reference in pronouns and relatives; too complicated or artificial a structure of the sentence, so that the sense is too long suspended by parentheses; the injudicious introduction of technical words and phrases; and, lastly, very long sentences. Ambiguity may be occasioned either by using some expression which is equivocal, or by ranging the words in such an order that the construction is rendered equivocal. The last fault proceeds either from great confusion of thought, which is commonly accompanied with intricacy of expression, or from affectation of excellence in the diction, evidenced by the injudicious use of figures, or from a total want of meaning. In these several ways, a speaker may express himself obscurely, and so convey his meaning imperfectly to the mind of the hearer; or express himself ambiguously, and so along with his own, convey a meaning entirely different; or express himself unintelligibly, and so convey no meaning at all. Dr. Campbell in his Philosophy of Rhetoric, vol. ii. book 2. chap. 6. has well exemplified and exposed these offences against *perspicuity*. It is justly observed by Quintilian, ubi supra, that by *perspicuity*, care is taken, not that the hearer *may* understand, if he will; but that he *must* understand, whether he will or not.

PERSPIRATION, *perspiratio*, in *Medicine*, the action of evacuating the superfluous juices of the body through the pores of the skin.

When this evacuation is copious enough to be perceived by the senses, as in sweat, the *perspiration* is said to be *sensible*; where it escapes the notice of the senses, as is the case in the ordinary state of the body, the *perspiration* is said to be *insensible*.

The word *perspiration*, used simply, and without any adjective, is to be understood of insensible *perspiration*.

This evacuation was indeed known to the ancients, Hippocrates, Galen, &c. but it was Sanctorius, the famous Paduan physician, who first brought it under any stated rules. To him we owe both the invention and perfection of the doctrine of *insensible perspiration*.

The vessels through which the *perspiration* is performed, lie obliquely open under the squamæ or scales of the cuticle or scarf-skin. They are inconceivably small: from a calculation of Leewenhoeck it appears, that the mouths of one hundred and twenty-five thousand of them may be covered with a common grain of sand.

The most considerable of these pores are the orifices of the ducts arising from the miliary glands.

Through these vessels there is continually transfusing a subtle humour, from every point of the body, and throughout the whole expanse of the cuticle.

The matter evacuated this way is found by certain experience to be more than equal to that evacuated all the other ways, i. e. by stool, urine, &c. Sanctorius found in Italy, under the circumstances of a moderate diet, middle age, and easy life, that the matter insensibly perspired was $\frac{5}{8}$ of that taken in for food: so that there only remained $\frac{3}{8}$ for nutrition, and for the excrements of the nose, ears, intestines, bladder, &c.

The same author shews, that as much is evacuated by insensible *perspiration* in one day, as by stool in fourteen days; particularly, that in the space of a night's time, about fifteen ounces are ordinarily discharged by urine, four ounces by stool; and above forty ounces by *insensible perspiration*.

He also observes, that if a man eat and drink eight pounds in a day, five pounds of it are spent in *insensible perspiration*; and adds, as to the times, that within five hours after eating, there is perspired about one pound; from the fifth to the twelfth hour about three pounds; and from the twelfth to the fifteenth scarce half a pound.

M. Dodart, from a number of experiments made for thirty-three years successively, assures us, that we perspire much more in youth than in age. In some persons the *perspiration* is so copious, that they void very little of the coarser excrements, though they eat very heartily.

The benefits of *insensible perspiration* are so great, that without it, Borelli says, animal life could not be preserved. The general cause of *perspiration* is the circulation and heat of the blood.

The great subtilty, equability, and plenty of the matter, thus perspired, its increase after sleep, &c. constitute the grand symptoms of a perfect state of health; and the chief means of preserving the same. On the contrary, the departing from these is the first sure sign, and, perhaps, the original cause, of diseases.

Perspiration is performed, preserved, and increased, by the viscera, vessels, and fibres; by motion or exercise as far as the first appearance of sweat; by moderate use of venery; by sleep of seven or eight hours, the body well covered, yet not loaded with bed-clothes; cheerfulness; light, fermented, yet solid food, not fat; pure, not heavy air, &c. The contraries of all these, as also the increase of the other excretions, diminish, prevent, and deprave it.

Hence we see the cause, effect, &c. of this perspirable matter, its use in preserving the parts soft and flexible, and in supplying what is lost, but chiefly in preserving the nervous papillæ moist, fresh, lively, and fit to be affected by objects, and to transmit their impressions.

Perspiration is also absolutely necessary, in the animal œconomy, for purifying the mass of blood, and discharging it of a number of useless heterogeneous particles, which might corrupt it. Hence it is, that upon a stoppage of the usual *perspiration* there arise so many indispositions, particularly fevers, agues, rheums, &c.

Too much *perspiration* occasions weakness, swoonings, sudden death; too little, or none at all, occasions the capillary vessels to dry, wither, and perish. Hence also the larger emunctories come to be obstructed; hence the circulation is disturbed, sharp humours retained; and hence putridity, crudity, fevers, inflammations, and imposthumes.

Cold prevents *perspiration*, by constringing the pores of the skin and thickening the liquors circulating in the cutaneous glands; heat, on the contrary, augments it, both by opening the excretory ducts of the glands, and by increasing the fluidity and velocity of the humours.

To determine the state and conditions of the *perspiration*, so necessary for judging of those of the body, Sanctorius invented a weighing chair, whereby he examined the quantity, degree, &c. of *perspiration* in several circumstances of the body, under several temperatures of the air, and in the several intervals of eating, drinking, sleeping, &c.

Some of the more extraordinary phenomena observed herewith, are, that for some time after eating the *perspiration* is least of all: that between the fifth and twelfth hour after meals *perspiration* is greatest: that riding either on horseback, in a coach or ship, &c. brisk motion on the ice, &c. but, above all, a brisk friction of the skin, promote *perspiration* surprisingly: and that *perspiration* is naturally always much less in women than in men.

Perſpiration is influenced by the paſſions of the mind. Thus anger and joy increaſe, and fear and ſadneſs leſſen, both *perſpiration* and urine. Anger cauſes a ſtrong motion in the membranes of the heart, and quickens its contraction and dilatation, and thereby quickens the contraction and dilatation of the blood-veſſels and ſecerning ducts, and of conſequence increaſes the diſcharges of *perſpiration* and urine; and that more or leſs, in proportion to the ſtrength and continuance of the paſſion.

Joy affects theſe diſcharges in like manner as anger. In the paſſions of fear and ſorrow, *perſpiration* and urine are leſſened, by the depreſſion of the activity of the ſoul under theſe paſſions. Dr. Bryan Robinſon of the Food and Diſcharges of Hum. Bodies, p. 77, ſeq.

The proportion of *perſpiration* to urine is increaſed by all thoſe exerciſes which increaſe the motion of the blood, and warm the ſkin.

We have an account of a perſon, who by paſſing many nights in aſtronomical ſpeculations, had his *perſpiration* ſo obſtructed by the cold and damp of the air in Holland, that a ſhirt he had worn for five or ſix weeks was as clean as if it had been worn but one day. The conſequence of this was, that he gathered ſubcutaneous waters, but was cured in time. Phil. Tranſ. N° 8. p. 138.

We have ſeveral obſervations, experiments, and tables, relating to the quantity of *perſpiration*, urine, and ſtool, in South Caroſina, by Dr. John Laning. See Philoſ. Tranſ. N° 470 and 475.

Some have ſuppoſed that the *perſpiration* of animal bodies, in a healthy ſtate, has the ſame effect upon air that breathing itſelf, viz. phlogiſticating and making it noxious; this is an opinion which Dr. Ingenhouſz has deduced from ſome experiments; and Dr. Macbride, Eſſays, p. 257, informs us, that having collected about two drams of ſweat, and mixed it with ſix drams of lime-water, he found that the mixture immediately became turbid, and in a ſhort time depoſited a light ſediment, like that afforded in ſimilar circumſtances by urine, and which effervesced as violently when ſpirit of vitriol was added. Whence he concludes, that air is thrown off from the fluids by *perſpiration* as well as by urine. But Dr. Prieſtley obſerving, that there is nothing we know of in the human frame which would lead any perſon to ſuſpect that air ever iſſues from the ſkin, from various experiments maintains, that perſpirable matter has no ſuch effect upon the air, leaving it as wholeſome or as fit for reſpiration as ever, as he concludes from the teſt of nitrous air. Hence he infers that it is only RESPIRATION, and not the *perſpiration* of the body, that injures common air. Exper. and Obſ. vol. v. ſect. 10.

PERSPIRATION *of plants*. See PLANTS.

PERTICA, a ſort of cornet, being the ſame with VERU.

PERTICA, among the Romans, a long rod for beating the fruit from trees. It was likewiſe uſed for a long meaſure. See PERCH.

PERTICATA, or PARTICATA *terræ*, in our *Old Law-Books*, is the fourth part of an acre, or a piece of ground containing one perch in breadth, and forty in length. See ROOD, and PERCH.

Continet in integra ſuperficie 40 *perticas*.

PERTICULAS, poor ſcholars of the iſle of Man. The king granted to *L. Macguin de inſula de Man, ſcholari, quandam elemoſinam vocatam* Perticulas, *ad ſuſtentationem cujuſdam pauperis ſcholaris, de inſula prædicta ad exercend. ſcholas, per progenitores noſtros quondam reges Angliæ datum & conceſſam*. Pat. Hen. 4.

PERU, *baſſam of*. See BALSAM.

PERVIGILIA, in *Antiquity*, an appellation given to nocturnal feſtivals, celebrated in honour of ſeveral deities, as Ceres, Venus, Fortune, &c. They were ſo called becauſe the nights were ſpent in waking.

PERVIGILIUM, in *Medicine*, exceſſive waking, or WATCHING.

PERVINCA, in *Botany*. See PERIWINKLE.

PERVISE, or PARVISE, a term in our *Old Law-Books*, ſignifying, according to Selden in his notes on Forteſcue, an afternoon's exerciſe, or moot, which the pleaders held for the inſtruction of the younger ſtudents; bearing originally the ſame name with the parriſæ in Oxford. See MOOT.

Mr. Sommer ſays, that PERVISE ſignifies *palatii atrium, vel area illa a fronte aulæ Weſtmonaſterienſis, hodie*, the *Palace-yard*: and Spelman thinks that the lawyers turned thither to meet their clients, not to hold moots.

PERUVIAN *bark*. See CORTEX *Peruvianus*.

PERUVIAN *emerald*. See EMERALD.

PERYGUA, in *Botany*, a name given by ſome authors to a plant of the caſſine kind, called the *caſſaberry* buſh, and by ſome the *Paraguay tea*.

PERYSIAS, a word uſed by authors to expreſs wine of the laſt year's vintage.

PERYSTAPHYLO *pharyngei*, in *Anatomy*, are two ſmall muſcles inſerted between the uvula and lower extremity of the internal ala of the apophyſis pterygoides; and running obliquely backwards on the ſides of the pharynx.

PES, a long meaſure, in Engliſh called FOOT.

PES *forceſtæ*. See FOOT *of the Foreſt*.

PES *leonis*, in *Botany*, a name by which ſome authors expreſs the *alchymilla*, or ladies-mantle.

PES *monetæ*, in *Ancient Records*, ſignifies a true and reaſonable adjuſtment of the real value of all current coin.

PESA, an old law-term for a WEIGH, or certain weight of cheeſe, wool, &c.

PESADE, or PESATE, in the *Manage*, that action taught a horſe, wherein he riſes with his fore feet, and bends them up to his body, without ſtirring the hind feet.

The *peſade* takes its name from the motion of the horſe, which, in this action, leans and lays all the weight of his body upon his haunches. To be perfect, the hinder feet, which ſupport the whole, ought to be fixed and immoveable, and the fore-part of the horſe more or leſs raiſed according as the creature will allow; but the fore-legs, from the knee to the feet, muſt always be extremely bent and brought under him.

The *peſade* is the firſt leſſon taught a horſe, in order to bring him to curvets, &c. unleſs he performs this well, he will never go well in any air: yet he is not to be taught it at the firſt riding.

This is the foundation of all the AIRS, and is neceſſary to diſpoſe and prepare the horſe for all ſorts of manages: however, great caution ſhould be uſed not to teach a horſe to riſe up, or ſtand upon his haunches, unleſs he is quite exact and obedient to the hand and heel: for in this caſe he would be thrown into diſorder, his mouth would be ſpoiled, the appuy falſified, and he would become reſtive. When he is fit for this exerciſe, work him upon the walk, the trot, and the gallop; ſtop him in the hand, keep him firm and moderately together; aid with the tongue, the ſwitch, and your legs; and when he begins to comprehend what you would have him do, encourage and careſs him; working him gently and by degrees. Sluggiſh and heavy horſes require, in the beginning, ſtronger and ſharper aids. There are other horſes, which are apt to riſe of themſelves; this ſhould be prevented by driving them forward. Berenger's Art of Horſemanſhip, vol. ii. chap. 16.

PESAGE, *peſagium*, a cuſtom or duty paid in certain markets, &c. for weighing of merchandizes, or wares.

PESATE. See PESADE.

PESCE *vacca*, the *cow-fiſh*, a name given by Auguſtino Scilla to a kind of dog-fiſh, not deſcribed by any author before his time, but accurately drawn by him in his book on petrifactions, on occaſion of its teeth: many ſpecies of the *glaſſopetræ* of the iſland of Malta, and other places, being plainly the ſame with the teeth in the jaws of this fiſh.

PESSARY, or PESSUS, formed from *πεσσος*, or *πεσσω*, which ſignifies the ſame, in *Medicine*, a ſolid medicament of the length and thickneſs of the finger, but of a pyramidal form; conveyed into the natural parts of a woman, to provoke, or to put a ſtop to the menſes, to prevent a deſcent of the matrix, or on other occaſions in diſorders of theſe parts.

The *peſſary* conſiſts of a piece of cork, or light wood, or of a little linen-bag full of powders, incorporated with wax, oil, and cotton, crammed cloſe together, to make it ſolid enough for intromiſſion.

At one end it is faſtened to a little ribband, by which it may be drawn out at pleaſure.

PESSOMANTIA, *Πεσσομαντια*, in *Antiquity*, the ſame with CLEROMANCY.

PESTERABLE, in our *Old Writers*, an epithet for ſuch wares as *peſter*, or take up much room in a ſhip. Stat. 32 Hen. VIII. cap. 14.

PESTILENCE, formed from *peſtis*, which ſignifies the ſame, in *Medicine*, an epidemical, malignant, and contagious diſeaſe, uſually mortal; popularly known under the name of PLAGUE.

PEST-*houſe*, a lazaretto, or infirmary, where goods, perſons, &c. infected, or ſuſpected to be infected, with ſome contagious diſeaſe, are diſpoſed, and provided for.

PESTILENCE-*wort*, in *Botany*. See BUTTER-*bur*.

PESTILENTIAL *carbuncle*. See CARBUNCLE.

PESTILENTIAL *diſeaſes*. See DISEASE.

PESTILENTIAL *fevers*, among *Phyſicians*, are ſuch as do not only afflict the patient with a vehement heat, but alſo with ſome malignant and venomous quality, and in ſome approach to the nature of the plague.

PESTIS. See PLAGUE.

PETALA, *petali*, in *Botany*, the leaves of a flower; ſo called to diſtinguiſh them from the folia, or leaves of the plant.

The word is formed from the Greek *πεταλον*, a *leaf*; which, in

in that language ſerves indifferently for the leaves of the plant, and thoſe of the flower.

By flower is properly meant, that aſſemblage of parts, called *petala*, *ſtamina*, *apices*, and *piſtil*, which ſerve for the propagation of the kind.

The coloured leaves, called *petala*, which encompaſs the other parts, are in reality no more than caſes or covers, to ſecure and ſereen the generative organs; unleſs, as Mr. Bradley conjectures, they may alſo ſerve to ſecrete ſome fine juice for the nouriſhment of the ſeed.

The *petal* is that part of the flower which conſtitutes the corolla; it generally diſtinguiſhes itſelf by its ſingular colour.

The *petal* is defined by Linnæus to be a corollaceous covering to the flower, meaning that it incloſes and defends it in the manner of a corolla, or wreath.

When the COROLLA conſiſts only of one *petal*, its lower tubular part is called the *tube*; its upper expanded part, the *limb*: when ſeveral *petals* go to make up the flower, the narrow part where they are inſerted is called *unguis*; their broader part towards the end, *bractea* or *lamina*.

The moſt eaſy diviſion of flowers, in regard to the matter of generation, is into ſimple ones; i. e. thoſe formed of ſtamina and piſtil only; and compound flowers, whoſe ſtamina and piſtil are encompaſſed with *petals*, called by Dr. Grew the *foliation*, and by Mr. Ray *folia*.

Compound flowers again, are either encompaſſed with a ſingle *petalum*, or piece; or with ſeveral pieces; the firſt of which are called *monopetalous*, the ſecond *polypetalous* flowers.

Again, from the regular or irregular configuration of the *petals*, Mr. Juſſieu makes another diviſion of flowers into claſſes; as regular and irregular *monopetalous*; regular and irregular *polypetalous*, &c.

That great botaniſt, the late Mr. Pitton Tournefort, fixed upon the moſt ſtriking and ſhewy parts of vegetables, as the foundation of his method and general diviſion of the vegetable world; which he has accordingly ranged into twenty-two claſſes.

The firſt is of the plants with a *monopetalous* or one-leaved flower, formed like a bell; and the flowers of this claſs he afterwards ſubdivides into four kinds; firſt, the *bell-faſhioned* flowers properly ſo called, as being very nearly of the regular ſhape of a bell; ſecondly, the *tubulate bell-faſhioned* flowers which are narrow and oblong; thirdly, the *expanded*, which open in form of a wide baſon; and, fourthly, the *globoſe*, the mouth of which is narrower than the body. In this claſs he comprehends the *mandrake*, *lily of the valley*, &c.

The ſecond claſs is of the plants with *monopetalous funnel-faſhioned*, and *rotated*, or wheel-like flowers. The flowers of this claſs he divides into two kinds only; the one repreſenting at its mouth, the bottom of an inverted cone, the other a ſalver or faucer; and theſe he diſtinguiſhes by the names of *funnel-faſhioned* and *ſalver-like* flowers: of this claſs are the *tobacco*, *henbane*, &c.

The third claſs is of what he calls the plants with *anomalous*, *monopetalous* flowers; of theſe he makes the variouſly-ſhaped *monopetalous* flowers of *birth-wort*, *fox-glove*, *fig-wort*, and ſome others; ſome of which repreſent a face, and others the ſnout of an animal: to diſtinguiſh the plants of this claſs the author however is obliged fairly to confeſs the imperfection of the method of claſſing by the *petals* alone, and call in the aſſiſtance of the different ſtructure of the ſeed-veſſels. In this claſs he comprehends the *toad-flax*, *butter-wort*, &c.

The fourth claſs is of the plants, which have a *monopetalous*, *labiated*, or lipped flower; which he defines to be ſuch a one as is narrow, like a pipe within, and expanded; and in form of lips at the mouth. In this claſs are comprehended the *ſage*, *clary*, *deadnettle*, *mint*, *balm*, &c.

The fifth claſs is of the plants with a *polypetalous*, *cruciform* flower; that is, ſuch a one as is compoſed of a number of leaves, diſpoſed in form of a croſs; and theſe he afterwards more nicely defines to be ſuch as are always compoſed of four *petals*, or leaves only, and thoſe ever diſpoſed in form of a croſs. Of this claſs are the *creſſes*, *muſtard*, *ſauce-alone*, &c.

The ſixth claſs is of the plants which have a *roſaceous*, or roſe-like flower. This he defines to be ſuch a one as is compoſed of many leaves or *petals*, diſpoſed like thoſe of the roſe into a round figure: the number of *petals*, he adds, is uncertain and indeterminate in this claſs; and that they are frequently five, and more rarely four than two. Of this claſs are the *chickweed*, *orpine*, *ſaxifrage*, *yew*, &c.

The ſeventh claſs is of the plants with *umbelliferous* flowers. Theſe he defines to be *polypetalous*, *roſaceous* flowers, whoſe cup goes off into a fruit compoſed of two ſeeds, cohering firmly together while green, but naturally ſeparating when ripe; and obſerves, that in this claſs the flowers are generally diſpoſed in great numbers together, and in the form of what the ladies call an *umbrella*, uſed to be carried over them to keep off the ſun; but he does not make this a neceſſary character of the claſs. The plants comprehended under this are *carrot*, *paſtnip*, *earth-nuts*, *elder-vel*, *fennel*, &c.

The eighth claſs is of the plants with a *caryophyllous*, or pink-like flower, which he defines to be ſuch a one as is compoſed of many *petals*, diſpoſed in an orbicular form, and ariſing each from the bottom of the cup, as from a tube, in the ſame manner as they do in the common pink. Of this claſs are the *catchfly*, *ſea-lavender*, *flax*, &c.

The ninth claſs is of the plants which have a *liliaceous*, or lily-like flower, which he defines to be ſuch a one as is compoſed of ſix *petals*, ſometimes indeed but three, but always divided however into ſix at the end. Here the author alſo again acknowledges the imperfection of claſſing by the *petals*, ſince here he takes in the aſſiſtance of the figure and diviſion of the ſeed-veſſel, which he ſays muſt always in this claſs be tricapſular, or divided into three cells; and plants which have this ſeed-veſſel, though their flowers are not ſtrictly of the lily-ſhape, are allowed to be truly of the claſs. Of this are the *aſphodel*, *ſaffron*, *flower-de-luce*, *tulip*, *crown-imperial*, &c.

The tenth claſs is of the plants with a *papilionaceous*, *papilionaceous* flower, or one that is compoſed of many *petals*, and in form reſembling a butterfly. Theſe flowers the author defines to be compoſed of four diſſimilar *petals*, which iſſue from a one-leaved cup, which is hollow, and like the conic paper-caſes people twiſt up to put ſpices, &c. in; and divided into many ſegments at the rim; and from this cup ariſes alſo the *piſtil* of the flower. The upper leaf in theſe flowers, which in ſome ſort repreſents the colours carried by ſoldiers in battle, he calls the *vexillum* or *enſign*; the lower, which is hollowed, and in form of a boat, the *keel*; and the two ſide ones the *wings*. The plants comprehended under this claſs are the *liquorice*, *pea*, *fenugreek*, &c.

The eleventh claſs is of plants with an *anomalous* or irregular *polypetalous* flower. Among theſe he comprehends ſuch of the *polypetalous* flowers as are of various ſhape, and compoſed of diſſimilar or irregular *petals*, and could not well be comprehended under any one expreſſive or determinate character. Of this claſs are the *violet*, *fumitory*, *dyer's-weed*, *wolfsbane*, &c.

The twelfth claſs is of the plants with a *floſculous* flower. This he defines to be one compoſed of a number of ſmall flowers, crowded cloſe together, and comprehended in the ſame general *calyx*, or cup; theſe flowers, which together compoſe this complex one, he obſerves are generally compoſed of only one *petal*, which is wider at the mouth than at the other end, and generally notched or divided there into many ſegments. He alſo has recourſe to the other parts of the flower for further deſcriptions; and comprehends under it the *thiſtles*, *knapweed*, *bluebottle*, &c. The thirteenth claſs is of the plants with a *ſemifloſculous* flower. Theſe he defines to be compoſed of a multitude of half flowers, each compoſed of one *petal*, hollow in its lower part, but in its middle and upper part flat and plain; and diſpoſed into a ſingle or manifold circle. He here alſo deſcribes the fructification of the plants of this claſs, and comprehends in it the *lettuce*, *dandelion*, *hawkweed*, &c.

The fourteenth claſs is of the plants with a *radiated* flower. Theſe flowers the author deſcribes to have two parts, a middle or *diſk*, compoſed of ſmall *ſtellate* flowers, and a *rim*, or *edge*, called the corona, which is made up of half flowers; and ſometimes, though ſeldom, of plain flat *petals*. Under this claſs are comprehended the *ſtar-wort*, *ragwort*, *golden-rod*, *ſunflower*, &c.

The fifteenth claſs is of the plants which have flowers compoſed of *ſtamina* or *threads*, ſuſtaining the *apices* or *capſules* of the fecundating farina. The author diſtinguiſhes theſe alſo by their *piſtil* changing into a ſingle ſeed enveloped in a huſk, and of this claſs makes the *ſorrel*, *orſmart*, *orrach*, the *graſſes*, *horſetails*, &c.

The ſixteenth claſs is of thoſe plants which the author ſuppoſes to have no flower at all; and yet to produce ſeeds. Of this claſs he determines the *fern*, *liver-wort*, and *adder's-tongue*, to be.

The ſeventeenth claſs is of thoſe plants whoſe flowers and fruit he ſays are both ordinarily wanting. Theſe he afterwards divides into the earth and water plants; among the firſt he reckons the *moſſes*, *muſhrooms*, &c. And among the others the *fucuſes*, *algæ*, *coralines*, &c. the flowers and ſeeds of which he obſerves we are as yet at leaſt ignorant of.

The eighteenth claſs is of the trees and ſhrubs, which have *apetalous* flowers, or flowers without *petals* or leaves at all. Of this claſs are the *aſh*, *box*, &c.

The nineteenth claſs is of the trees and ſhrubs which have *catkins* or *juli* for their flowers. Theſe the author ſays conſiſt either of *ſtamina* and *apices* alone, that is, of

the threads or capsules of the farina; or they are composed of these with some little leaves affixed to a long slender axis: these *catkins* he observes are always in a different place from the fruit; and that, sometimes on the same, sometimes on different trees. Of this class are the *walnut, oak, beech*, &c.

The twentieth class is of trees and shrubs, which have a *rosaceous* flower; and of this are the *elm, lotus, storax, olive*, &c.

The twenty-first class is of the trees and shrubs which have a *papilionaceous* flower; among which are reckoned the *broom, bean, trefoil, judas-tree*, &c. See BOTANY, and FLOWER; and *Tables* VIII. IX. and X. *of Botany*.

It is very easily seen, that this is far from a strictly accurate method; the author has indeed assisted it with figures, which are very useful and instructive; and, as the judicious Linnæus observes, more is in reality to be learned from them, than from all the author has said. Linnæus has well observed, that this method is neither perfect nor sufficiently distinctive; the glory of instructing the botanist with truth and certainty was indeed reserved for that author alone, who, when he had shewn the imperfection and uncertainty of all the before established methods, planned out an absolutely new one, founded on the unalterable parts of plants, their organs of FRUCTIFICATION.

Nature exhibits peculiar art in the folding up of the *petala* in the perianthium, before they begin to blow or expand: of these foldings Dr. Grew notes the following varieties; viz. the close couch, as in roses; the concave couch, as in blattaria flore albo; the single plait, as in peas-blossoms; the double plait, as in blue-bottles; the couch and plait together, as in marigolds, &c. the rowl, as in ladies-bower; the spire, as in mallows; and lastly, the plait and spire together, as in convolvulus doronici folio.

The calyx, or perianthium, sometimes serves plants in lieu of *petala*.

PETALISM, *petalismus*, πεταλισμος, in *Antiquity*, a kind of EXILE or BANISHMENT, for the term of five years.

The *petalism* at Syracuse was nearly the same thing as the *ostracism* at Athens, except that the latter was for ten years, and the former only for five.

The *petalism* was performed by the people's writing the name of the person condemned, on a leaf; whence the term from πεταλον, *leaf*.

PETALODES, πεταλωδης, a name given to urine, when it seems to have little leaves, flakes, or scales, in it.

PETAMINARIUS, in *Antiquity*, a name given to certain persons who performed extraordinary feats of activity; took perilous leaps, vaults, &c.

The word is formed from the Greek, πεταννυμι, πεταω, *I fly*. Some authors write it *petisminarius*; and derive it from *petimen*, which, according to Festus, signifies the hunch of a camel; alluding to the manner wherein these operators bend the body in exhibiting postures, &c.

PETARD, in *War*, a kind of engine of metal, somewhat in shape of a high-crowned hat, or truncated cone; serving to break down gates, barricades, draw-bridges, or the like works which are intended to be surprised.

The *petard* may be considered as a piece of ordnance, very short, narrow at the breech, and wide at the muzzle; made of copper mixed with a little brass; or of lead with tin; usually about 8.5 inches within at the bottom; the diameter at the beginning of the round part is six, and distant from the lower base nine inches: the circular part is described from the point where the perpendicular to the sides meets the middle line or axis; the thickness of metal is 1.6 inches: there is a brim at the bottom that projects the metal by two inches, and is one inch thick, in which are six holes of half an inch diameter, which serve for screws to fasten the *petard* on a board in a firm manner; there is a cavity within at the bottom, half an inch deep, and as much in height to fix a board, in order to keep the charge in the *petard* before it is fixed to the beard or plank. There are likewise two handles of about three inches from the flat ring, five inches long, ¾ thick, and 3.8 from the outside to the metal. Lastly, a hole of an inch diameter is made either at the top, or on the side, to screw in an iron fuse by which the powder is fired, which fuse is filled with a slow composition, in order that when it is lighted, the petardier may have time to retire out of danger. See the section of a *petard* in *Tab.* II. *Gunnery, fig.* 13.

Petards are made of various dimensions; but the biggest should not weigh above seventy pounds when loaded and fixed to its plank, and the least not less than forty-five or fifty. The common and best way of loading the *petard* is to fill it gradually with powder, and between every layer of two or three inches thick, to put a wooden mould into the *petard*, which should be beat upon with a mallet, so as to press the powder as close together as possible, without bruising the grains; and when it is quite full, the board is put upon the powder, and over this a cloth with rosin, and bound round the brim with packthread, to keep the charge and board together till the *petard* is screwed on the plank or board; then the part that exceeds the brim is cut off, and the other being pressed by the brim prevents any air from coming to the powder. The board to which the *petard* is fixed has two iron bands on the back, placed cross-ways, and a hook to hang it up against the gate or door, by means of a screw, when it is to be used. Some moisten the powder with spirits of wine, and dry it in the sun, in order to make it stronger, and then sprinkle every layer of powder of two inches thickness with mercury, upon which they lay powder again, and press it down, sprinkling it with mercury, till the petard is filled.

Its use is in a clandestine attack, to break down gates, bridges, barriers, &c. to which it is hung, which it does by means of the wooden plank. It has been also used in countermines, to break through the enemies galleries, and give vent to their mines: but in later years the use of *petards* has been discontinued.

Petards are sometimes also made of wood, bound round with iron hoops.

The invention of *petards* is ascribed to the French Huguenots in the year 1579. Their most signal exploit was the taking the city Cahors by means hereof, as we are told by d'Aubigne.

PETARDIER, in the *Military Art*, is he who loads, fixes, and fires the *petard*.

PETASITES, *butter-burr*, in *Botany*. See BUTTER *Bur*.

PETASUS among the *Romans*, a covering for the head, not unlike our hats; it had a broad brim, and was used in journeys to save the face from being sun-burnt.

The PILEUS differed from the *petasus*, as having no brim. The *petasus* is observed upon the head of ancient figures of Mercury; who wore it in the quality of the god of travellers and merchants.

PETECHIÆ, spots in the skin, like flea-bites, which come out in some fevers, which are hence called *petechial* or *spotted fevers*. See FEVER.

PETECHIAL, an appellation given to a malignant, epidemical kind of fever; wherein the skin breaks out in *petechiæ*, or purple spots.

The *petechial* FEVER is also called *febris lenticularis*, and *pulicosis*.

PETELMA, in the *Turkish Military Orders*, is the procurator general of the effects of the Janizaries. When any one dies under the protection of this body, he seals up their houses, to secure the tenth part of their effects; which are due to the Janizaries.

PETERERO. See PETRERO.

PETER-*penny*, an ancient levy, or tax, of a penny on each house throughout England, paid to the pope.

It was called *Peter-penny*, because collected on the day of St. *Peter ad Vincula*; by the Saxons it was called *Rome fesh*, i. e. the fee of Rome, and also *Romescot*, and *Romepenny*, because collected and sent to Rome; and lastly, it was called *hearth-penny*, because every dwelling-house was liable to it, provided there were thirty pence over *peculiar* belonging to it; nay, and every religious house; the abbey of St. Albans alone excepted.

This *Peter-penny* was at first given as a pension or alms, by Ina, king of the West Saxons, in the year 727, being then in pilgrimage at Rome: and the like was done by Offa, king of the Mercians, throughout his dominions, in 794: and afterwards by Ethelwulph, through the whole kingdom, in the year 855.

It was not intended as a tribute to the pope, but chiefly for the support of the English school or college at Rome: the popes, however, shared it with the college: and at length found means to appropriate it to themselves.

At first it was only an occasional contribution; but it became at last a standing tax; being established by the laws of king Canute, Edward the Confessor, the Conqueror, &c.

The bishops who are charged with the collecting it, employed the rural deans and archdeacons therein.

Edward the Third first forbad the payment, but it soon after returned, and continued till the time of king Henry VIII. when Polydore Virgil resided here as the pope's receiver-general.

It was abolished under that prince, and restored again under Philip and Mary; but it was finally prohibited under queen Elizabeth.

St. PETER'S *wort*, *ascyrum*, in *Botany*, a genus of the *polyadelphia polyandria* class. Its characters are these: the empalement of the flower is four-leaved; and the flower has four oval petals, the two outer are large, and placed opposite, the two inner small; in the centre is situated

an oblong germen, attended by a great number of briſtly ſtamina, which are reduced at their baſe to four bodies; the germen becomes an oblong pointed-ſeed veſſel, filled with ſmall round ſeeds. Miller enumerates four, and Linnæus three ſpecies.

PETESIA, in *Botany*, a genus of the *tetrandria monogynia* claſs: its characters are, that the corolla has a ſingle petal, and is funnel-ſhaped; the ſtigma is bifid, and the fruit a polyſpermous berry. There are two ſpecies.

PETIA, a word uſed by medical writers in different ſenſes. It is commonly underſtood to mean a piece of rag, uſed to the medicinal ingredients in, to be uſed by infuſion in liquors; but *petia oculi* ſignifies an hæmorrhage of the eye.

PETICULÆ, the ſame as *petechiæ*, purple ſpots appearing on the ſkin in malignant fevers.

PETIGO, a word uſed by ſome authors for IMPETIGO.

PETILUS *flos*, a name uſed by ſome botanical authors for the African marygold.

PETIMBUABA, in *Ichthyography*, the name of a fiſh caught in the American ſeas, and called by ſome, in Engliſh, *the tobacco-pipe fiſh*; a name more commonly uſed for the AGUS *ſiringatus*.

It grows to the length of three or four feet; its body is like that of an eel, long and ſlender; and its mouth without teeth; the length of the noſe is conſiderable, and the upper jaw is ſhorter than the lower; its eyes are remarkably large, not ſmaller than a hazel nut, and ſomething of the ſame figure; its ſkin is ſmooth, like that of the eel, and of a liver-colour on the back and ſides, with ſeveral rows of blue ſpots diſpoſed in three rows on the back, two on the head, and one on each ſide; there are alſo ſome green ſpots every where interſperſed among the blue ones. The belly is white, but has ſomething of a brownith red caſt, and is flat. It is a well-taſted fiſh.

PETIOLATE *leaf*, among *Botaniſts*. See LEAF.

PETIOLE *petiolum*, among *Botaniſts*, expreſſes that ſtalk which ſupports the leaves of a plant, as the peduncle does the fructification.

Some uſe the word *petiolum* to denote the whole middle rib of a leaf of any plant, which is the ſtrongeſt part of it, and runs from the ſtalk, by which the leaf adheres to the tree or plant, to its extremity, and from which the lateral fibres or nerves, as they are uſually called, commonly ariſe.

The authors, who have written on the ſubject of the anatomy of leaves, have had occaſion to be accurate about the diſtinctions of the ſeveral parts; and they have called this main or middle rib, the *petiolus*. The ſide branches going off from this, they call *rami*; and the ſubdiviſions of theſe into more minute fibres *furculi*: theſe generally are interwoven into a reticular plexus one with another, and make up the ſubſtance of the leaf, with the bladders of a liquid matter, which are contained in their interſtices. All theſe ſolid parts of leaves, the *furculi* and *rami*, as well as the *petiolus*, are congeries of oblong fibres extended evenly together, and collected into one body; and the fibres in all parts of plants are divided into two kinds; the one containing juices, and called *ſucciferæ*; the other giving paſſage only to air, and therefore called *tracheæ*.

Leewenhoek has diſtinguiſhed the ſucciferous veſſels into two kinds, which he calls veins and arteries: the latter, he obſerves, receive the ſap from the root, where it is firſt collected, and carry it up to the reſt of the plant, and the others bring it back again from thence, in the manner of veins.

Perrault has joined a great number of experiments to Leewenhoek's, in order to prove this ſyſtem of the juice-veſſels, but Fontenelle, and ſome others, have doubted either the exiſtence, or at leaſt the uſe, of the TRACHEÆ or air-veſſels, ſuppoſing them either imaginary veſſels, or deſtined for other purpoſes. The vine branches, however, examined either by a microſcope, or by a good eye in a good light, will ſhew evidently that ſuch veſſels exiſt, and that in very great numbers; and the veſſels in the *petiole* and *furculi* of leaves, when ſtrictly examined, are found to be of both theſe kinds. Act. Eruditi. 1722.

PETIOLUS, a word uſed by botanical writers to expreſs the ſtalk of a fruit.

PETIT *ſage, jury, larceny, ſerjeanty, ſeſſion, treaſon.* See the ſubſtantives.

PETIT *guet*, Fr. in *Military Language*, is carried on by a ſlight party, commanded by an expert partiſan, conſiſting of between one and two thouſand men, ſeparated from the main army, in order to ſecure the camp on a march, to reconnoitre the enemy or the country, to ſeize their poſts, convoys, or eſcorts, to plant ambuſcades, and to practiſe every ſtratagem for ſurpriſing or diſturbing the enemy.

PETITA *terra*. See SUMMONS.

PETITIO *principii*, in *Logic*, a begging the queſtion, or precarious ſuppoſing a thing to be true, or taking it for granted, when it really remains either dubious, or elſe I expreſly denied.

PETITION, *petitio*, a ſupplication in form, made by an inferior to his ſuperior; eſpecially to one having ſome juriſdiction.

To ſubſcribe a *petition* to the king to frighten him into change of his meaſures, inſinuating, that if he denied, many thouſands of his ſubjects will be diſcontented, &c. is included among the contempts againſt the king's perſon and government, tending to weaken the ſame, and is puniſhable by fine and impriſonment. 1 Hawk. P. C. 80. The right of *petitioning* is, however, unqueſtionable; proviſion can be taken, that under the pretence of petitioning, the ſubject be not guilty of any riot or tumult: for preventing which, it is provided by the ſtat. 13 Car. II. ſtat. 1. cap. 5. that no *petition* to the king, or either houſe of parliament, for any alterations in church or ſtate, ſhall be ſigned by above twenty perſons, unleſs the matter thereof be approved by three juſtices of the peace, or the major part of the grand jury, in the county; and in London by the lord mayor, aldermen, and common council: nor ſhall any *petition* be preſented by more than ten perſons at a time, on pain in either caſe, of incurring a penalty not exceeding 100*l.* and three months impriſonment. But, under theſe regulations, it is declared by the ſtatute 1 W. and M. ſtat. 2. cap. 2. that the ſubject hath a right to *petition*; and that all commitments and proſecutions for ſuch petitioning are illegal.

PETITION *of appeal* to the houſe of lords is the dernier reſort of any ſubject who thinks himſelf aggrieved by any interlocutory order or final determination in the court of chancery. This juriſdiction of the houſe of peers is ſaid to have begun in 18 Jac. I. and the firſt *petition*, which appears in the records of parliament, was preferred in that year; and the firſt that was heard and determined was preferred in a few months after; both levelled againſt the lord keeper Bacon, for corruption and other miſbehaviour. It was afterwards warmly controverted by the houſe of commons, in the reign of Charles II. But the diſpute has long ſince terminated. We may obſerve that no new evidence is admitted in the houſe of lords, upon any account, for this is a diſtinct juriſdiction.

PETITION *of bankruptcy*, is a *petition* preſented to the lord chancellor by one creditor, to the amount of 150*l.* or by three or more to the amount of 200*l.* upon which he grants a COMMISSION to certain perſons, who are then ſtyled commiſſioners of bankrupts. The petitioners muſt be bound in a ſecurity of 200*l.* to make the party amends, in caſe they do not prove him a BANKRUPT. And if they receive any money or effects from the bankrupt, as a recompence for ſuing out the commiſſion, ſo as to receive more than their rateable dividends of his eſtate, they forfeit not only what they have ſo received, but their whole debt.

In conſequence of this *petition*, and when the commiſſion is awarded and iſſued, the commiſſioners are to meet, at their own expence, and to take an oath for the due execution of their commiſſion, and to be allowed a ſum not exceeding 20*s.* per diem each, at every ſitting. When the commiſſioners have received proof of a perſon's being a trader, and of his having committed an act of bankruptcy, they declare him a bankrupt, giving notice thereof in the Gazette, and appointing three meetings. At one of theſe meetings ASSIGNEES ſhall be choſen; and at the third meeting, at fartheſt, which muſt be on the forty-ſecond day after the adverſement in the Gazette, the bankrupt, upon notice ſerved upon him or left at his uſual place of abode, muſt ſurrender himſelf perſonally to the commiſſioners, and conform to the ſtatutes of bankruptcy; or, in default thereof, be guilty of felony, and ſhall ſuffer death, and his goods and eſtate ſhall be diſtributed among his creditors. The bankrupt is to be examined by the commiſſioners, who may alſo ſummon and examine his wife or any other perſon; and if he refuſe to anſwer fully to any lawful queſtion, or to ſubſcribe his examination, they may commit him to priſon without bail, till he makes and ſigns a full anſwer. The bankrupt is alſo to make a full diſcovery of all his eſtate and effects, and in caſe he conceals or embezzles any to the amount of 20*l.* or with-holds any books or writings, with intent to defraud his creditors, he ſhall be guilty of felony without benefit of clergy. After the time allowed to the bankrupt for ſuch diſcovery is expired, any other perſon voluntarily diſcovering any part of his eſtate, before unknown to the aſſignees, ſhall be intitled to five per cent. out of the effects ſo diſcovered, and ſuch reward as the commiſſioners and aſſignees ſhall think proper: but any truſtee wilfully concealing the eſtate of any bankrupt, after the expiration of the forty-two days, ſhall forfeit 100*l.* and double the value of the eſtate concealed, to the

creditors. For the farther proceſs in a caſe of BANKRUPTCY, ſee CERTIFICATE.

We ſhall only here obſerve farther, that by ſtatute 19 Geo. II. cap. 32. no money paid by a bankrupt to a *bona fide* or real creditor, in a courſe of trade, even after an act of bankruptcy done, is liable to be refunded: nor by 1 Jac. I. c. 15. ſhall any debtor of a bankrupt, that pays him his debt, without knowing of his bankruptcy, be liable to account for it again.

PETITION *of right*, was a parliamentary declaration of the liberties of the people, aſſented to by king Charles I. in the beginning of his reign: in which it is enacted, that none ſhould be compelled to make or yield any gift, loan, benevolence, tax, and ſuch like charge, without conſent by act of parliament; nor, upon refuſal ſo to do, be called to make anſwer, take any oath not warranted by law, give attendance, or be confined, or otherwiſe moleſted concerning the ſame, &c. And that the ſubject ſhould not be burthened by the quartering of ſoldiers or mariners; and all commiſſions for proceeding by martial law to be annulled, and none of like nature iſſued thereafter, leſt the ſubject (by colour thereof) be deſtroyed or put to death, contrary to the laws of the land, &c. See ſtat. 3. Car. I. cap. 1.

PETIVERIA, *in Botany*. See *Guinea* HENWEED.

PETOLA, in *Zoology*, a ſpecies of coluber, the ſcuta of whoſe abdomen are two hundred and nine; and the ſquamæ of the tail ninety. See COLUBER.

PETOLIN, in *Natural Hiſtory*, the French name for a ſhrub of the piſtachia kind, famous for affording bladders or tubercles on its leaves and tender branches, in the manner of the common turpentine-tree; which are found full of inſects. Theſe inſects are always found to be of the puceron kind, and ſome of them are winged, others not, as is known to be the caſe in that genus of animals. Theſe bladders, and thoſe of the turpentine-tree, called its *horns*, have been by ſome ſuppoſed to be the natural production of the trees, but they are in reality only a peculiar ſpecies of bladder-galls, formed by theſe animals, one female of which making her way into the leaf, while the young raiſes its covering membrane into a bladder, in which ſhe produces her young ones; which by ſucking its ſides, derive the juices to it, and occaſion its increaſe. See PUCERON.

PETRARIA, *in Ancient Writers*, is ſometimes taken for a quarry of ſtone.

In other places *petraria* is uſed for a ſort of engine of war, wherewith ſtones were caſt on the enemy; chiefly uſed in ſieges, &c.

PETRE *oil*, ſtone, the ſame as petroleum. *See* PETROL.

PETREA, in *Botany*, a genus of the *didynamia angioſpermia* claſs. Its characters are theſe: the flower hath an empalement of one leaf, cut into five acute ſegments; it has one petal, with a ſhort tube, cut above into five almoſt equal ſegments, which are expanded; it has four ſhort ſtamina ſituated in the tube, two of which are a little longer than the other, terminated by ſingle ſummits; and four germina ſupporting a ſhort ſtyle, crowned by an obtuſe ſtigma; the germina become four ſeeds, wrapped in a fringed cover. There is but one ſpecies, a native of La Vera Cruz, in New Spain.

PETREL, the name of a very remarkable bird, called *procellaria*, by authors. See FULMAR, SHEAR-*water*, and STORM-*finch*.

PETRIDIA, in *Natural Hiſtory*, the name of a genus of foſſils of the SCRUPI kind, of a plain uniform ſtructure, of no great variety of colours, and emulating the external form of pebbles.

Of this genus there are twelve known ſpecies. Hill.

PETRIFACTION, or PETRIFICATION, formed from πετρα, *ſtone*, and *fio* or *facio*, *to become*, or *to make*, in *Phyſiology*, the act of converting fluids, woods, and other matters, into ſtone.

The faculty of *petrifying* wood is aſcribed to ſeveral ſprings, lakes, &c. and the ancient naturaliſts mention a river whoſe waters turned bodies into marble, by mere contact; nay, which, being drunk, *petrified* the viſcera of the drinker.

Flumen habent Cirenes, quod potum ſanos reddit
Viſcera, quod tactis inducit marmora rebus.

Seneca relates, that the mud of this river was of ſuch a nature as to harden and glue together the parts of bodies. At, ſays he, the duſt of Puzzuoli, by barely touching water, becomes ſtone; ſo this water, by touching any ſolid, penetrates and grows to it; whence things caſt into it are immediately taken out ſtones. Pliny obſerves very well, that wood caſt into this river is preſently found covered with a ſtony bark or rind; and ſubjoins the names of ſeveral other rivers which do the ſame: particularly the river Silarus, near Tarentum, whoſe waters are nevertheleſs found very wholeſome. To Pliny's liſt we might add many more among ourſelves; particularly the Loch Lohmond, in Scotland, Loch Neagh, in Ireland, &c. But, in effect, there does not ſeem any real tranſmutation of the woody nature into the nature of ſtone, in any of theſe caſes: all that is done is this; the ſtony particles, which before floated in the liquor, are now lodged on the ſurface, or depoſited in the pores of theſe ſubſtances, in ſuch manner, and in ſuch plenty, as to leave little elſe but the appearance of a ſtone.

Petrifactions are moſt frequently nothing elſe but incruſtations of ſtony particles, which ſurround the bodies immerged, and, as falts, ſhoot upon and adhere to them.

Varenius has a conjecture, that waters only petrify woods by means of certain minute, ſharp, and pointed particles lodged therein, which cut the longitudinal fibres of the wood in an infinite number of points, and thus deſtroy the form by which they were diſtinguiſhed from ſtone.

The knowledge of this part of natural hiſtory is but of very late years arrived at any degree of perfection. Dr. Hooke, Steno, Boerhaave, and Auguſtino Scilla, have been among the firſt who treated judiciouſly of theſe things; but great honour is to be done to Fabius Columna, who, before the time of any of them, publiſhed two admirable diſcoveries upon the parts of aquatic and terreſtrial animals, and of plants buried in the earth, and which he had himſelf ſeen dug up in the mountains of Andria, Apulia, and other places. He boldly declares, that theſe could be depoſited there by no other means but by the general deluge in the days of Noah; and enters into the reaſons why, in ſome places, theſe remains of animal and vegetable bodies are found perfect and entire, and in others corrupted or altered; and obſerves, that they anſwer ſo exactly in every lineament to the recent bodies of the ſame kind, that there can be no doubt of their having once been alſo ſuch.

It is a very remarkable obſervation, in regard to the really and certainly determining the origin of *petrified* ſhells, that they are not all alike altered by lying in the earth, but that they differ according to the matter among which they have lain to *petrify*. Thus the ſame ſpecies of ſhell *petrified* in a looſe ſand-ſtone is never nearly ſo hard as when *petrified* in a ſolid quarry, or in a hard lime-ſtone; ſo that it is evident they were brought into the places where they now lie, in the ſtate of ſhells, and that the ſtone in which they are depoſited, having imparted to them its own nature, they are harder or ſofter, in proportion to its hardneſs. We find in pits where the ſhells are depoſited in looſe earth, that they are often not *petrified* at all, but rendered more ſoft and friable than before.

In places where the incruſtations of moſſes and other vegetables happen, ivy is one which very frequently undergoes the ſame fate. The beauty and elegance of the *petrified ivy* of Derbyſhire with us has been long famous. In the mountains near Matlock-baths, in that county, there are many grottos which afford great quantities of this *petrified ivy*, as it is called, and of other incruſtations of the ſame kind. The beauty of theſe caverns is ſcarce to be conceived; their roofs are hung with ſtalactitæ and ſtalagmitæ, in form of cluſters of grapes, and the incruſted plants are many of them ſo delicate and tender that they fall to pieces under the touch. It is very common in theſe places to ſee ivy creeping along the rock; in ſome parts the ſame branch will be found only incruſted in the common way; in other parts the ſtony matter will ſo penetrate its pores, that the wood and leaves ſhall appear wholly petrified, and in others the ſame branch ſhall be yet freſh and vegetating.

Hazel trees often make a part of theſe incruſtated matters, and appear in this ſtate very beautiful, their roots and branches being in ſome parts only thinly incruſted, in others more thickly and firmly petrified. Among theſe alſo, as in the ivy, there are continually ſhooting up a number of young branches, which after a time will all ſhare the ſame fate. Philoſ. Tranſ. N° 436. p. 353.

Nothing can give a more lively and beautiful idea of the whole buſineſs of *petrifaction*, than this appearance of the ſeveral ſtates or ſtages of it in the ivy, and other vegetables in theſe places. It is evident, that in theſe places not only the water diſtilling out of the rocks is able to depoſit ſtony matter on the vegetables, &c. in form of incruſtations, but even the ſteams and exhalations, being highly ſated with theſe ſtony particles, are capable of working the ſame effect. This is evidently the caſe in regard to ſeveral pieces of the incruſtated ivy, which have never been in the way of water, and yet are as completely covered with ſtone as the reſt; and this is the only method in which the ſtony matter is conveyed into the internal parts of the plants that are really petrified in theſe places. For experience ſhews in regard to theſe, that they are not petrified firſt, and afterwards incruſted, but

but it is plain, that the incruſtation is made firſt, and that afterwards, when in a long ſpace of time the vegetable matter within is petrified and waſted away, the cavity that it leaves by this means is filled up afterwards with the ſame ſtony matter. It is evident that this inner part of the *petrifaction* was not formed while the vegetable yet exiſted by the inſinuation of ſtony matter into its pores, but that it is a mere maſs of ſtone added afterwards, ſince it has never any the leaſt trace of the inner ſtructure of the vegetable: and this ſtony matter, though uſually much more firm and ſolid than the outer cruſt, muſt in many caſes have been formed merely by vapours, as it is in places where water is never found to come on any occaſion.

The water of ſome ſprings may be ſo loaded with ſtony matter, as perhaps by penetrating the pores of wood, and other lax bodies, to increaſe greatly their ſpecific gravities, yet ſurely it is contrary to the laws of matter to ſay, that there are any hidden properties in that water capable of changing the bodies put into it, into other bodies ſpecifically different. A piece of wood put into one of theſe ſprings may in time loſe its texture and coherency, by the admittance of heterogeneous particles of different attractions; but the cauſe of coherency in the parts of the original body muſt ceaſe and be diſſolved, before it can be ſaid to become a part of any other body whatever. Afterwards, indeed, the ſpace that was poſſeſſed by the parts of the original body may be ſupplied by thoſe of the new one, ſo as to make in time an uniform ſtone in the ſhape of the original plant; but if this petrified plant be ſtill kept in the place, where the ſame petrifying quality continues to act upon it, it will loſe even that ſhape, and become a part of that body which is contiguous to it, and ſo a great number of theſe plants thus petrified, arranged near to one another, will compoſe large maſſes, and perhaps whole ſtrata of ſtone. This is clearly the caſe in regard to many of the lime-ſtone rocks about the places where the *petrified ivy* is found; and perhaps it might be carried ſo far as to ſtrengthen our conception about the general formation of the ſtrata of lime-ſtone and marble; that appearing to be every where (notwithſtanding that Dr. Woodward diſputes them much more expeditiously) but eſpecially in the Peak of Derbyſhire, ſuch a *petrifaction* as has been deſcribed, only perfectly finiſhed. Philoſ. Tranſ. N° 456. p. 356.

The echini marini, and other ſuch hollow and open-mouthed ſhells, are very often found filled up with earth or ſtone, the ſame with that in which they lie; and refuſe matter is ſometimes found among this, ſuch as the fragments of other ſhells, and the ſpines of ſome other echini. All theſe ſerve to prove that the ſhell, in its recent ſtate, was ſuſpended in water among ſuch ſubſtances as theſe. And it is not to be ſuppoſed, with ſome authors, that they are found originally as foſſils within the ſhell; ſince, in this caſe, they would be ſometimes doubtleſs found of ſuch a ſize as could not have got in at the mouth of the living animal; but this is never the caſe. And upon the whole it appears very plain, that after the membranes, which covered the mouths of theſe ſhells in their recent ſtate, were decayed or waſhed away, theſe extraneous bodies found entrance at them along with the marle, chalk, ſtone, or whatever other ſubſtance they were among, which was evidently all ſoft and fluid at that time.

The *petrified* vertebræ of fiſhes cannot be ſuppoſed real foſſile productions, but are plainly remains of animals; and when examined ever ſo accurately, they are found to agree with the ſame bones in the recent animal in every lineament.

Seilla mentions a foſſile lobſter's claw preſerved in his muſeum, and found in the hills near Meſſina, in which a piece of a ſcallop-ſhell was found clenched juſt in the manner in which that animal ſeizes its prey. Thoſe who ſuppoſe theſe foſſils to be really produced in the earth ſurely cannot ſuppoſe that there could be any ſeminal principle only for the claw of an animal. In Poland there is a kind of ſtone called *nice kamni*, which they bring from a place called by the ſame name. This ſtone has very much the appearance of the grain of wood, and is probably wood *petrified*. Rzaczinſki, in his hiſtory of Poland, mentions the place, and tells us, that there are many roots and parts of the trunks of trees *petrified* there. He tells us alſo of an old beech-tree in Podolia, whoſe lower part is not only *petrified*, but that into the hardeſt and pureſt of the common ſtones; it being converted wholly into flint, and ſerving the country people thereabout for their common uſes as ſuch.

The author tells us, indeed, that the lower parts of trees become *petrified* there as they ſtand, and while the upper parts continue growing; but this ſeems ſcarce credible.

We have indeed ſome other accounts of the ſame nature, but not from authors of ſufficient authority to build our faith on, in ſo ſeemingly unnatural a caſe. This author in particular, ſeems too credulous in many inſtances; among other things, giving us an account of ſome earthen veſſels found at conſiderable depths in the earth, which he ſuppoſes to have been formed there by nature. We have other accounts beſide this of foſſile urns, but the authors of them all have either miſtaken the cruſtated ferruginous bodies for urns, or elſe they have ſuppoſed things natural which are certainly artificial. Rzaczinſki's Hiſt. Polon.

Mr. Boyle mentions a kind of ſandy earth found in England, which turns wood into ſtone, though there be no *petrifying* ſpring near the place: and this, he ſays, is done in a better manner than by any water he ever ſaw. See Works Abr. vol. i. p. 161.

PETREFACTIONS, *animal*, a term uſed to expreſs ſuch *petrifactions* as are found in the ſeveral parts of the bodies of living creatures.

Of theſe the human body affords many, which are the occaſions of very terrible and generally incurable diſeaſes. The Philoſophical Tranſactions afford us two very ſingular inſtances of this ſort of *petrifactions*; the one in a woman, whoſe whole left kidney was entirely *petrified*, not being filled up in its cavity with a ſtony concretion, as frequently happens in nephritic caſes, but its whole ſubſtance converted into abſolute ſtone, only covered with a thin ſkin.

The other inſtance is in the caſe of a conſumptive perſon, whoſe lungs were found, on diſſection, full of ulcers, and thoſe having almoſt all of them, more or leſs gravel in them; but this was not all, for ſeveral large pieces of the lungs were found, as the kidney in the other inſtance, wholly concreted into ſtone, only covered with a thin ſkin. Phil. Tranſ. N° 71. See *Foſſil* BONES, *Foſſil* SHELLS, MARINE *remains*, and *Foſſil* IVORY. See alſo FOSSILS.

PETRIFYING *waters*. Alonſo Barba gives an account of ſome *petrifying waters* of Peru, which greatly exceed all thoſe we have in Europe in the quantity of ſtony matter they contain. He tells us, that they ſoon choak up their own paſſage by the ſtony matter they depoſit there; and that all the cattle that drink of them die. He adds another ſtory, which he probably took a little too haſtily upon credit, which is, that they have moulds of the ſhape of our bricks, which they fill with this water, and that on being expoſed to the ſun a few days, the water is wholly converted into a ſtone of the ſame ſhape; and that they build their houſes and other buildings with theſe ſtones.

PETROBRUSSIANS, a religious ſect, which aroſe in France, and the Netherlands, about the year 1110; ſo called from their leader, *Peter Bruys*, a Provencal, who made the moſt laudable attempt to reform the abuſes and remove the ſuperſtitions that diſgraced the beautiful ſimplicity of the goſpel: and after having engaged in his cauſe a great number of followers, during a laborious miniſtry of twenty years continuance, was burnt in the year 1130, by an enraged populace, ſet on by the clergy.

The chief of Bruys's adherents was a monk, one Henry; from whom the *Petrobruſſians* were alſo called HENRICIANS.

Peter the Venerable, abbot of Clugny, has an expreſs treatiſe againſt the *Petrobruſſians*; in the preface to which, he reduces their opinions to five heads.

1. They denied that children before the age of reaſon can be juſtified by baptiſm; in regard it is our own faith that ſaves by baptiſm. 2. They held, that no churches ſhould be built, but that thoſe that already are ſhould be pulled down; an inn being as proper for prayers as a temple, and a ſtable as an altar. 3. That the croſs ought to be pulled down, and burned, becauſe we ought to abhor the inſtruments of our Saviour's paſſion. 4. That the real body and blood of Chriſt are not exhibited in the euchariſt, but merely repreſented by their figures and ſymbols. 5. That ſacrifices, alms, prayers, &c. do not avail the dead.

P. Langlois objects Manicheiſm to the *Petrobruſſians*; and ſays, they maintained two gods, the one good, the other evil: but this we rather eſteem an effect of his zeal for the catholic cauſe, which determined him to blacken the adverſaries thereof, than any real ſentiment of the *Petrobruſſians*.

PETROCOSSYPIUS, in *Ornithology*, a name given by ſome authors to the bird more uſually called from its colour the CÆRULEUS.

It lives among the rocks, in woody mountains, and ſings very ſweetly.

PETROJOANNITES, the followers of Peter John, or Peter Joannis, i. e. Peter the ſon of John, who lived in the twelfth century; whoſe doctrine was not known till after his death; when his body was taken out of his grave, and burnt. His opinions were, that he alone had the knowleſge of the true ſenſe wherein the apoſtles preached the goſpel; that the conſecrated bread was not the form of man; that there is no grace inſuſed by baptiſm; and that Jeſus Chriſt was pierced with a lance on the croſs before he expired

PETROL, *petroleum*, q. d. *petræ oleum*, oil of petre, or rock oil, an oleaginous juice, issuing out of the clefts of rocks; and found floating on the waters of certain springs. Beside artificial and vegetable oils, i. e. those drawn from plants, &c. by expression, there are also natural and mineral oils issuing of themselves from the entrails of the earth, called by a common name *petrols*, or *petrolea*.

The more fluid *petrolea*, says Dr. Lewis, have been distinguished by the name of NAPHTHA; and the thicker by those of PISSASPHALTHUM and PISSELEUM.

These, according to all appearance, must be the work of subterraneous fires, which raise or sublime the more subtile parts of certain bituminous matters that lie in their way.

These parts, being condensed into a liquor by the cold of the vaults of rocks, are there collected, and ooze thence through clefts and apertures, with which the disposition of the ground furnishes them.

Petrol then, is a liquid bitumen, only differing by its fluidity from other bitumens, as asphaltum, jet, amber, and the like subfiances.

The naphtha, which is either a liquid, or at least a very soft bitumen, is nearly allied to *petrol*.

Hitherto there has been little *petrol* found, except in hot countries. Olearius says, he saw above thirty springs of it near Scamachia, in Persia: there are also *petrols* in the southern provinces of France; but the best are those in the duchy of Modena, first discovered by Ariosto, a physician, in 1640, in a very barren valley, twelve leagues from the city of Modena.

Three canals are there dug with great expence in the rock; by which three different kinds of *petrol* are discharged into little basons or reservoirs: the first, as white, clear, and fluid as water, of a brisk penetrating smell, and not disagreeable; the second of a bright yellow, less fluid, and of a less brisk smell than the white; the third of a blackish red, of thicker consistence, and a smell more approaching that of bitumen.

There are many varieties of these oils in regard to colour, fluidity, subtility, and the pungency of their smell and taste; the most fluid are, in general, the most subtile and pungent. With us they are commonly sophisticated.

Mr. Boulduc made several experiments with the *petroleum* of Modena, an account of which he gave to the Paris Academy.

It easily took fire on being brought near a candle, and that without immediately touching the flame; and when heated in any vessel, it will attract the flame of a candle, though placed at a great height above the vessel, and the vapour it sends up taking fire, the flame will be communicated to the vessel of heated liquor, and the whole will be consumed. It burns in the water, and when mixed with any liquor swims on the surface of it, even of the highest rectified spirit of wine, which is $\frac{1}{3}$ heavier than pure *petroleum*. It readily mixes with all the essential oils of vegetables, as oil of lavender, turpentine, and the rest, and seems very much of their nature: nor is this very strange, since the alliance between these bodies is probably nearer than is imagined, as the essential oils of vegetables may have been originally mineral ones, and drawn up out of the earth into the vessels of the plant. Mem. Acad. Par. 1715.

Petroleum, when shaken, yields a few bubbles; but they sooner subside than in almost any other liquor, and the liquor resumes its clear state again almost immediately. This seems owing to the air in this fluid being very equally distributed to all its parts, and the liquor being composed of particles very evenly and nicely arranged.

The extensibility of this oil is also amazing. A drop of it will spread over several feet of water, and in this condition it gives a great variety of colours, that is, the several parts of which this thin film is composed act as so many prisms.

The most severe frost never congeals *petroleum* into ice, and paper wetted with it becomes transparent, as when wetted with oil; but it does not continue so, the paper becoming opake again in a few minutes, as the oil dries away.

Spirit of wine, which is the great dissolvent of sulphur, has no effect upon *petroleum*, not even with ever so long a digestion. It will not take fire with the dephlegmated acid spirits, as oil of cloves, and other of the vegetable essential oils do; and in distillation, either by balneum Mariæ, or in sand, it will neither yield phlegm nor acid spirit; but the whole rises in its own form, leaving in the retort only a little matter, thick as honey, and of a brownish colour. Whoever, therefore, would use this oil in medicine, must take it as nature has prepared it, as having no power to make any alteration in it. Mem. Acad. Paris, 1725.

Alonso Barba, in his Book of Metals, gives a very melancholy instance of the power of *petroleum* of taking fire at a distance: he tells us, that a certain well, yielding *petroleum* on the surface of its water, being to be repaired, the workman took down into the well with him a lantern and a candle in it; there were some holes in the lantern, through which the *petroleum*, at a considerable distance, drew out the flame of the candle, and, taking fire, burst up with the noise of a cannon, and tore the man to pieces.

The people of Mount Claro, in Italy, have some years since found out a much easier way of finding *petroleum*, than they formerly had been used to.

This mountain abounds with a sort of greyish slate, which lies in large horizontal beds, mingled with strata of clay, and large quantities of a spar of that kind called by the Germans *selenites*; which is the common sort, that ferments with acids, and readily dissolves in them, and calcines in a small fire. They pierce these slates in a perpendicular direction till they find water, and the *petroleum*, which had been dispersed among the cracks of those slates, is then washed out by the water, and brought from all the neighbouring places to the hole or well which they have dug, on the surface of the water on which it swims after eight or ten days. When there is enough of it got together, they bale it from the top of the water with brass basons, and it is then easily separated from what little water is taken up with it. It is remarkable, that all the *petroleum* got by this means is white, whereas that of Modena is yellow, and that of Parma brown. These wells or holes continue to furnish the oil in different quantities for a considerable time, and, when they will yield no more, they pierce the slates in some other place. Mem. Acad. Scien. Par. 1736. See NAPHTHA.

Petroleum is never used among us; but the French give it internally in hysteric complaints, and to their children for worms: some also give it from ten to fifteen drops in wine, for suppressions of the menses. This, however, is rather the practice of the common people than of the faculty.

It has also been sometimes recommended to be taken internally in nervous complaints, and as a diuretic; but it is chiefly used as an external stimulant, against rheumatic pains, palsies, chilblains, &c. See *British* OIL.

PETROLEUM *Barbadense*. See BARBADOES *tar*.

PETROMARULA, in *Botany*, a name given by several authors to the pyramidal RAPUNCULUS of the island of Crete, called, by Mr. Tournefort, *rapunculus Creticus seu pyramidalis alter*.

PETROMYZON, the *stone-sucker*, in the Linnæan system of *Zoology*, the name of a genus of AMPHIBIA *nantes*, comprehending the LAMPREY, &c.

The name is originally Greek, and is derived from the words πετρος, *a stone*, and μυζω, *to suck*; this fish being usually found in rivers, adhering to the stones by sucking, and so keeping its place.

The characters of this genus, according to Artedi, are these: the foramina, or apertures of the branchiæ, or lungs, are seven on each side; they are placed longitudinally, and beside these, there is one single aperture in the head, placed immediately between the eyes; the body is long, and nearly of a cylindric figure; it is smooth, and has only two fins, and those are both placed on the back. The species of this genus, enumerated by Artedi and Linnæus, are three.

PETRONEL, a sort of HAND-GUN or hand-gun.

PETRONELLUS, in *Ornithology*, a name under which some have described the BUNTING.

PETRONIA *marina*, in *Ornithology*, the name of a small bird of the ortanline kind, or nearly allied to that genus. Its beak is strong and sharp, like that of the chaffinch; its head is a brownish grey, but has usually a long whitish streak running along it; its neck is ash-coloured, and at the bottom is variegated with black; the rump is of a brownish green; the long wing-feathers are blackish, with edges and tips of green, and are white underneath; the breast is of a dusky white, and the tail brownish, variegated with yellow. It is however, distinguished from all other birds by a fine large yellow spot, which is has on the middle of its throat.

PETRO-*pharyngei*, in *Anatomy*, are muscles of the PHARYNX, inserted in the lower part of the extremity of the apophysis petrosa. These serve, with the cerato-pharyngei and pterygo-pharyngei to draw the middle portion or great cavity of the pharynx upward.

PETROSA *ossa*, in *Anatomy*, a denomination given to the fifth and sixth bones of the head, called also *ossa temporum*, because they shew the age of man; the hairs hereon turning grey before any of the rest.

The upper part of each is squamous, or scaly; the lower is *petrosa*, i. e. hard or stony: and hence they come here to be more particularly denominated *petrosa*.

The *ossa petrosa* are the smallest proper bones of the cranium: their upper part is semicircular, and their lower

is of a firm ſtructure. They are ſituated in the lateral and lower parts of the head; bounded at top by the ſquamous future, which joins them to the parietalia; and behind by the lambdoides, which joins them to the occipital, and connects them to the os ſphenoides. Each has two ſinuſes, before and behind the ſphenoides: the exterior lined with a cartilage, receiving the proceſs of the lower jaw; the interior receives the lower part of the ſinus lateralis of the dura mater.

Each, again, has four proceſſes; three external, and one internal: of the external, the firſt is called *zygomaticus*, or *os jugale*; the ſecond *maſtoides* or *mammillaris*; the third *ſtyloides*: each whereof ſee under its proper article. The internal proceſs is properly called the *os petroſum*: this is pretty long and large, containing the whole meatus auditorius, and cavity of the tympanum.

The chief uſes of theſe bones are to complete the globe of the ſkull, to ſerve for the articulation of the lower jaw, and for the inſertion of many muſcles, and laſtly, to contain the organ of hearing.

PETROSELINI *radix, parſley-root*. See PARSLEY.

PETROSELINUM *Macedonicum*, in the *Materia Medica*, the name of a ſeed uſed in medicine. The plant which produces it is a native of the warm countries; and the ſeed ſhould be choſen for uſe, clean, well fed, longiſh, and of a brownith green colour, and well taſted, and aromatic; in quality it reſembles the common PARSLEY, but is weaker and leſs grateful; it is aperitive, provokes urine and the menſes, and expels wind; and, in form of a cataplaſm, is ſaid extremely to help the gout: it is an ingredient alſo in the Venice treacle. See BUGLOS.

PETROSUM *ſal*, in *Natural Hiſtory*, a name given by ſome of the old writers to the nitre of Egypt, uſed in the ancient times; and by others to the common nitre, which we uſe at preſent, and call by a ſimilar name, *ſal petræ*.

PETTIA, *Πεττεια*, in the *Ancient Muſic*, a Greek term to which we have no correſponding one in our language.

The melopœia, i. e. the art of arranging ſounds in melodious, ſo as to make melody, is divided into three parts, which the Greeks call *legis, mixis*, and *chreſis*; the Latins *ſumptio, mixtio*, and *uſus*; and the Italians *preſa, meſcolamento*, and *uſo*. The laſt of theſe is called by the Greeks, *ſtaſeis, pettiæ*, and by the Italians *pettia*.

Pettia, or *petteia*, then, is the art of making a juſt diſcernment of all the manners of ranging or combining ſounds among themſelves, ſo as they may produce their effect, i. e. may expreſs the ſeveral paſſions intended to be raiſed, thus: e. gr. it ſhews what ſounds are to be uſed, and what not; how often any of them are to be repeated; with which to begin, and with which to end; whether with a grave ſound to riſe, or an acute one to fall, &c.

It is the *petteia* that conſtitutes the manners of the muſic; it being this that chooſes out this or that paſſion, this or that motion of the ſoul, to be awakened; and whether it be proper to excite it on this or that occaſion. The *petteia* therefore is in muſic much what the manners are in poetry.

We do not ſee whence the denomination ſhould have been taken by the Greeks, unleſs from *πεττεια*, their game of chels; the muſical *petteia* being a ſort of combination and arrangement of ſounds, as chels is of pieces called *πεττοι*, calculi, or chels-men.

PETTY *bag*, an office in chancery; the three clerks whereof record the return of all inquiſitions out of every ſhire, and make all patents of cuſtomers, gaugers, comptrollers, &c. See CLERK.

PETTY-*chaps*, in *Ornithology*, the MOTACILLA *hippolais*, in the Linnæan ſyſtem; the inſide of the mouth is red; the head, neck, back, and wings, are of an olivaceous aſh-colour; the quill-feathers darker, edged with olive; the inner coverts of the wings yellow; the breaſt white, tinged with yellow; the belly of a ſilvery white; the tail duſky; and the legs bluiſh. This bird is called in Yorkſhire the *beam-bird*, from its neſting under beams in out-buildings, &c. Pennant.

PETTY *conſtable*. See CONSTABLE.

PETTY-*fogger*, formed from the French, *petit*, little, and the Saxon, *fogere, fotier*, or *cuvier*, a little ſhifting ſolicitor or jobber in law-diſputes, without either ſkill or conſcience.

PETTY, or PETIT *larceny*, in *Law*. See LARCENY.

PETTY *warrs*. See ORDERS.

PETTY *pokes*, among *Confectioners*, a ſort of ſmall pies, made of a rich cruſt, and filled with ſweet-meats.

PETTY-*ſingles*, among *Falconers*, are the toes of a hawk.

PETTY *ſuits*, in the *Sea Language*, a competent allowance of victuals, according to the number of the ſhip's company.

PETTY, or PETIT *treaſon*, in *Law*. See TREASON.

PETTY-*whin*. See FURZE, and REST-*harrow*.

PETULANTIUM *feſtum*, in *Antiquity*, a feſtival celebrated by the Athenians and Lacedæmonians in honour of the moon, under the name of Venus: at which the men aſſiſted, dreſſed in women's cloaths; and the women in the habits of men.

PETUNTSE, or, as it is uſually called *petunſe*, one of the two earths or foſſile ſubſtances of which the porcelain ware of China is made. The other is named KAOLIN.

The *petunſe* is ſprinkled all over with bright glittering particles; it is beaten to powder, and afterwards made up into a ſort of bricks, and in that form it is ſent to the places where it is to be wrought; it is of a hard texture, and of a ſomewhat greeniſh colour. Mr. Reaumur, of the Academy of Sciences of Paris, who was extremely induſtrious in ſearching into the nature of porcelain, obtained ſome ſpecimens of the *petunſe*, both in its native ſtate, and in form of the brick, which is given it after it is powdered and reduced to a paſte.

Mr. Reaumur found that the *petunſe* was ſo far from being an earth, as uſually ſuppoſed, that it was truly of the nature of the European flint or pebble, as he eſtabliſhes the character of that body: but to underſtand this rightly, it is to be obſerved, that this author makes the flints and pebbles a very large claſs of bodies, ſome of which are more, ſome leſs tranſparent; and that this *petunſe* is of the nature of the coarſer, or leſs tranſparent kind, the ſurface of which, when broken, is not ſo ſmooth and poliſhed as that of the ordinary flint. This ſubſtance is probably a ſpecies of GYPSUM rather than of flint or talc. By ſome experiments of Mr. Scheffer, in the Sweediſh Tranſactions, for the year 1753, it appears to be a glittering, flaky, ſemi-tranſparent maſs, like the *lapis ſpecularis*, of a light greeniſh-grey colour, and remarkably heavy. It was not acted upon by acids, and in the fire it burſt and fell in pieces, and calcined into a white powder, interſperſed with a red ferruginous matter. Calcined in contact with the fuel, it emitted ſtrong ſulphureous vapours, like the other gypſa, and became quite white, conſiderably firm, and coherent, and ſemi-tranſparent.

The great character of theſe ſtones for the porcelain manufactures is, however, that they are very eaſily vitrified, without the aſſiſtance of any ſalt, and without the immediate contact of the fire, the operation ſucceeding in a crucible, which is not at all the caſe in regard to the European flints, they very differently melting alone in a crucible, and then only into a whitiſh opake glaſs.

It being certain from hence, that one of the two ingredients of the china-ware is eaſily vitrifiable, it follows, from the experiment of the whole mixture, or china-ware not being reducible into a glaſs in large fire, that it is a compoſition of a vitrifiable, and a not vitrifiable (or at leaſt not eaſily vitrifiable) ſubſtance; and conſequently, that the kaolin is a ſcarce vitrifiable body, and that the reſult of the action of fire on a mixture of theſe two is a ſemivitrification; which is what we call the China-ware.

If we, therefore, could, in Europe, provide the materials of China, or ſuch as were like them, we might reaſonably hope to ſucceed; and this appears far from improbable. The *petunſe* is eaſily ſupplied by many of our own earths, ſtones, and ſands, as nothing is required in it more than a property of running eaſily into a white glaſs. The kaolin ſeems moſt to be reſembled by our European rales. Mem. Acad. Par. 1727.

PEUCEDANUM, *hog-fennel*, in *Botany*. See *Hog's* FENNEL.

PEVET. See PIVOT.

PEVETS, in a *Watch*, the ends of the ſpindle of a wheel in a WATCH. The holes into which they run, are called *pevet-holes*.

PEWIT, in *Ornithology*, the Engliſh name of a common bird of the *larus*, or ſea-gull kind, called by ſome authors *larus cinereus*, and by other *cepphus*, and in ſome of the counties of England the *black-cap*, and *ſea-crow*. This is the *larus ridibundus* of Linnæus.

It is about the ſize of a pigeon; its beak and legs are red; its head and throat of a greyiſh black, and its neck, tail, breaſt, and belly white; the middle of its back grey; it has its Engliſh name from its note, which ſeems to expreſs the word *pewit*, and is a kind of hoarſe laugh. It is affirmed by many, that the head of this bird is only black at a certain ſeaſon of the year.

Pewits are birds of paſſage, reſorting to pools and ſens in ſome of the inland counties, particularly Staffordſhire, in the ſpring, and after the breeding-ſeaſon diſperſing to the ſea-coaſts. The young were formerly much eſteemed and fattened for the table. Plot relates, that at the death of the lord of the ſoil, they ſhift their quarters for a certain time. There was a piece of ground near Portſmouth, which formerly produced 40*l.* a year to the owner, by the ſale of *pewits*. Ray and Pennant.

PEWIT is alſo a name given to the baſtard plover or LAPWING.

PEWTER, a factitious metal, uſed in domeſtic utenſils: its baſis is tin, and it conſiſts of three different ſtandards: viz. that which is called plate-metal, of which plates and diſhes are made, which is formed of tin and regulus of antimony, in the proportion of one hundred and twelve pounds of the former to ſix or ſeven pounds of the latter: the next metal inferior to this is called trifling metal, and is lowered one half-penny per pound in worth, by alloying it with lead; of this metal ale-houſe pots are made: the lower ſort of metal is ſtill farther alloyed by lead, ſo as to reduce the value two pence in a pound lower than plate-metal; of this, which is called lay-metal, wine-pots are made.

Pewter has occaſionally ſerved for money. In the Philoſophical Tranſactions, M. Patland informs us that king James II. turned all the *pewter* veſſels, &c. of the proteſtants in Ireland he could *ſeize*, into money; half-crowns were ſomewhat bigger than half-pence, and other pieces in proportion.

He ordered it to be current in all payments: whence, our author obſerves, people abſconded for fear of being paid their debts: he alſo mentions crown-pieces of this metal, with this legend on the rim, *melioris ſubſtra fati*.

PEZIZA, *cup-muſhroom*, in *Botany*, a genus of the claſs of *cryptogamia*, and order of *fungi*. This *muſhroom* is bell-ſhaped and ſeſſile. Linnæus enumerates eight ſpecies.

PHACA, in *Botany*. See *Baſtard Milk* VETCH.

PHACOIDES, a word uſed by the ancient phyſicians to expreſs any thing that in ſize and ſhape approached to a lentil. Thus the cryſtalline humour of the eye was ſo called.

PHACOPTISANA, a medicine often mentioned by the ancient writers as a nouriſhing and ſtrengthening thing: it was a peliſan with lentils.

PHACOSIS, a word uſed by the ancients to expreſs a diſorder of the eye, appearing in form of a black ſpot, of the ſize and round figure of the lentil.

PHÆCASIA, in *Antiquity*, a kind of ſhoes.

PHÆNICOPTERUS. See FLAMINGO.

PHÆNOMENON, or PHENOMENON, φαινομενον, formed from φαινω, *I appear*, ſtrictly an appearance in phyſics, an extraordinary appearance in the heavens, or on earth; either diſcovered by obſervation of the celeſtial bodies, or by phyſical experiments; and whoſe cauſe is not obvious. Such are meteors, comets, uncommon appearance of ſtars and planets, earthquakes, &c. Such alſo are the effects of the magnet, phoſphorus, &c.

The *phænomena* of comets are inconſiſtent not only with the ſolidity of the heavens, ſuppoſed in the Ptolemaic hypotheſis, but equally with the plenitude of the heavens, aſſerted by the Carteſians.

That hypotheſis is beſt which ſolves moſt *phænomena*. Sir Iſaac Newton ſhews, that all the *phænomena* of the heavenly bodies follow from the attraction of gravity, which intercedes thoſe bodies; and almoſt all the *phænomena* of the leſſer bodies from the attraction and repulſion between their particles; ſo ſimple is nature.

PHENOMENOS, *parallax of a*. See PARALLAX.

PHAETON, in *Ornithology*, a genus of the *anſeres*, in the Linnæan ſyſtem. Its characters are, that the bill is ſharp, ſtrait, and pointed; the noſtrils oblong; and the hinder toe turned forward. There are two ſpecies, viz. the FLAMINGO, and TROPIC *bird*.

PHAGEDÆNA, φαγεδαινα, formed of φαω, *to eat*, in *Surgery*, &c. a deep, bloated ulcer, which eats and corrodes the neighbouring parts.

PHAGEDÆNIC *medicines*, ſuch as are uſed to eat off fungous or proud fleſh.

PHAGEDÆNIC *ulcer*. See PHAGEDÆNA, and ULCER.

The Ephemerides of the academy of the Curioſi Naturæ relate, that *phagedænic* ulcers have been frequently cured only with ſheeps dung.

PHAGEDÆNIC *water*, in *Chemiſtry*, denotes a water made from quick-lime and ſublimate; ſo called from its efficacy in the cure of *phagedænic* ulcers.

To prepare this water, they put two pounds of freſh quick-lime in a large earthen pan, and pour upon it about ten pounds of rain-water; theſe they let ſtand together two days, ſtirring them frequently: at laſt leaving the lime to ſettle well, they pour off the water by inclination, filtrate it, and put it up in a glaſs bottle, adding to it an ounce of corroſive ſublimate in powder; which, of white, becomes yellow, and ſinks to the bottom of the veſſel. The water, being ſettled, is fit for uſe, in the cleanſing of wounds and ulcers, and to eat off ſuperfluous fleſh, and eſpecially in gangrenes; in which caſe may be added to it a third or fourth part of ſpirit of wine.

PHAGESIA, φαγησια, in *Antiquity*, a feſtival in honour of Bacchus, celebrated during the DIONYSIA.

It was otherwiſe called *phagiſpoſio*, φαγισποσια; which names come from φαγω, *to eat*, and πωω, *to drink*; becauſe it was a time of good cheer.

PHAGON, φαγων, in *Antiquity*, a feſtival of the ſame nature with that called PHAGESIA.

PHAGRUS, the *ſea-bream*. The Arteſian ſyſtem of ichthyology does not allow this fiſh a peculiar generical name, but makes it a ſpecies of the large genus of the *ſpari*: the author diſtinguiſhes this from the others by the name of the *reddiſh* SPARUS, with the ſkin hollowed into a ſinus at the roots of the back-fins.

PHAGUS, in *Botany*, a name given by many authors to the eſculus, or ſweet and eſculent oak, found in Greece and Dalmatia.

PHALACRA, a word uſed by Hippocrates to expreſs all the blunt inſtruments uſed in ſurgery; ſuch as probes and others, with buttons at the ends.

PHALACROCEPHALUS *indicus*, in *Ichthyology*, the name of an anadromous fiſh of the Eaſt Indies. Its neck and head appear naked and bald, as it were; it is all over of a greyiſh white in colour, and is variegated with red ſpots about the mouth; the eyes are large and very prominent, and their irides yellow; its uſual ſize is about a foot and a half in length, and it lives part of its time in the ſea, and part in rivers; it is an extremely delicate taſted fiſh, and eſteemed one of the fineſt of that part of the world. It is called by the Dutch *kuckop*.

PHALÆNA, in *Zoology*, a genus of the *lepidoptera* order of inſects; the characters of which are, that the antennæ are ſetaceous, ſenſibly attenuated from the baſe to the apex; the wings are moſt commonly declined. Linnæus enumerates four hundred and ſixty ſpecies, under the ſeveral titles of *phalæna*, *atlacus*, *bombyx*, *noctua*, *geometra*, *tortrix*, *pyralis*, *tinea*, and *alucita*. See PAPILIO.

PHALAIA, a word invented by Baſil Valentine, and uſed as the name of a *panacæa*, or univerſal medicine; but Roſlink has ſince uſed it to expreſs a tincture of ſalap.

PHALANGER. See OPOSSUM.

PHALANGIUM, in the *Hiſtory of Inſects*, the name of a peculiar genus of *ſpiders*, the characters of which are theſe: they do not move regularly and evenly as other *ſpiders*, but hop in the manner of fleas. This was a character recorded of them by Pliny and the ancients, and is found at this time in all ſpecies. They have a ſquare forehead; and in this are placed eight eyes of different ſizes, and diſpoſed in form of a part of a circle; they have alſo the fore-legs greatly longer and ſtronger than any of the others. Of theſe there are four principal kinds. See OPILIO.

PHALANGIUM *Apulum*, the *Apulian phalangium*, a name given by authors to that large and poiſonous ſpecies of ſpider, called by the vulgar the TARANTULA, from the name of a city of Calabria, Tarantum; near which it is very common.

PHALANGIUM, in *Botany*. See SPIDER-*wort*.

PHALANGOSIS, in *Surgery*, the name of a tumor and relaxation of the eye-lids, which is often ſo great as to deform the eye, and very much impede viſion. Sometimes the relaxed eye-lid ſubſides or ſinks down, occaſioned either by a palſy of the muſcle which ſuſtains and elevates the eye-lid, or elſe from a relaxation of the cutis above, from various cauſes. Sometimes alſo an œdematous or aqueous tumor is formed on the eye-lids, ſo as almoſt entirely to exclude viſion; but this laſt caſe ſhould be well diſtinguiſhed from the other, and may be remedied without much difficulty, by the uſe of internal and topical medicines; ſuch as purges and diuretics given inwardly, and a compreſs dipped in warm ſpirit of wine and lime-water.

But in the paralytic or relaxed caſe, the uſe of cordial and nervous medicines muſt be propoſed internally, and outwardly, baſtam of Peru and Hungary water are to be employed. If all theſe fail, the remaining method is to extirpate a ſufficient quantity of the relaxed cutis; and then, after healing up the wound, the remainder will be ſufficiently ſhortened. Heiſter.

PHALANX, φαλαγξ, in *Antiquity*, a huge, ſquare compact battalion, formed of infantry, ſet cloſe to one another, with their ſhields joined, and pikes turned croſs-ways; inſomuch that it was almoſt impoſſible to break them.

It conſiſted of eight thouſand men: Livy ſays, that this ſort of battalion was invented by the Macedonians, and that it was peculiar to them; whence, among writers, it is ſometimes called the *Macedonian phalanx*.

St. Evremont obſerves, that the Macedonian *phalanx* had the advantage in valour and ſtrength over the Roman legion.

PHALANX, *phalanges*, is alſo applied, by anatomiſts, to the three rows of ſmall bones which form the FINGERS.

PHALANX, in *Natural Hiſtory*, a term uſed by Dr. Woodward, and ſome other writers of foſſils, to expreſs an arrangement of the columns of that ſort of foſſile coralloide body found frequently in Wales, and called *lithoxylon*.

In the great variety of ſpecimens which are found of this, ſome

some have the whole *phalanx* of columns cracked through, and others only a few of the external ones; but these cracks never remain empty, but are found filled up with a white spar, as the smaller cracks of stone usually are. This is not wonderful, as there is much spar in the composition of this fossil; and it is easily washed out of the general mass to fill up these cracks, and is then always found pure, and therefore of its natural colour, white.

The *lithostrotion*, or general congeries of these phalanges of columns, is commonly found immersed in a grey stone, and found on the tops of the rocky cliffs about Milford in Wales. It is usually erect, though somewhat inclining in some specimens, but never lies horizontal. It seems to have been all white at first, but to have been since gradually tinctured with the matter of the stone in which it lies. The single columns, which form each *phalanx*, are usually round or cylindric, though sometimes flatted and bent; some of them are also naturally of an angular figure; these, however, are not regular in the number of their angles, some consisting of three sides, some of five, and some of seven; some are hexangular also, but these are scarce. They are from five or six to fifteen inches in length; and the largest are near half an inch over, the least about a quarter of an inch; the greater number are very equal to one another in size; but the sides of the columns being unequal, the same column measures of a different thickness when measured different ways; the phalanges or congeries of these are sometimes of a foot or more in diameter.

The columns are often burst, as if they had been affected by external injuries; and it is evident, that they were not formed before several other of the extraneous fossils; for there are found sometimes shells of sea-shells and entrochi immersed and bedded in the bodies of the columns. It appears plainly from hence, that when these bodies were washed out of the sea, and tossed about in the waters which then covered the tops of these cliffs, this elegant fossil, together with the stony bed in which it is contained, were so soft, that these other bodies found entrance into their very substance, and they were formed, as it were, upon them. This fossil takes an elegant polish, and makes in that state a very beautiful appearance, being of the hardness of the common white marble, and carrying the elegant structure visible in the smallest lineaments. Woodward's Coll. of Foss. p. 13.

PHALARIS, *Canary grass*, in the Linnæan *System of Botany*, the name of a peculiar kind of grass called *phalaroides* by Scheuhzer and others; and with this author making a distinct genus of plants of the *triandria digynia* class; the characters of which are, that the cup is a glume, containing only one flower; this glume is large, bivalve, obtuse, and compressed, each of the valves being of a boat-like shape, flatted, obtuse above, with strait edges meeting one another in parallel lines; the flower is also bivalve, and is smaller than the cup, the exterior valve of it being oblong, pointed, and folded, the interior much smaller; the stamina are three capillary filaments, shorter than the cup; the antheræ are oblong; the germen of the pistil is roundish; the styli are two in number, and are capillary ones; the stigmata are hairy; the flower serves for a close covering to the seed, not at all gaping from it; the seed is single, smooth, and roundish, but pointed at both ends. There are nine species.

PHALARIS's *Bull*, in *Ancient History*, was a brazen bull for tormenting criminals, constructed by Perillus the Athenian, in order to flatter the cruelty of *Phalaris*, tyrant of Agrigentum. The artist, demanding too great a reward for his contrivance, was the first who suffered in it. Some have treated this fragment of ancient history as a fable; but we learn from Diodorus Siculus, lib. xiii. cap. 13. that Scipio Africanus, when he razed Carthage, about two hundred and sixty years after the destruction of Agrigentum, found among other things this bull, and restored it to the inhabitants of Agrigentum, where it was to be seen when Diodorus wrote his history, viz. in the reign of Augustus.

PHALAROPE, in *Ornithology*, is a species of the TRINGA in the Linnæan system. Mr. Pennant gives the following general characters of this species: the bill is strait and tender; the nostrils minute; the body and legs like those of the sand-piper, and the toes furnished with scalloped membranes. He also more particularly describes the grey *phalarope*, or *tringa lobata* of Linnæus, and the red or *tringa hyperborea* of the same author.

PHALERA, the name of a bandage for the nose, described by Galen in his Treatise on Bandages.

PHALERÆ, among the *Ancients*, *horse-trappings*.

PHALUCUS, or PHALAECUS, in *Poetry*, a kind of verse, in use among the Greeks and Latins; consisting, like the Sapphic, of five feet; the first a spondee, the second a dactyl, and the three last trochees.

The *phalæcian* is very proper for epigrams. Catullus excelled in it. Its original author is not known; though some have said it derives its name from its inventor.

PHALLICA, φαλλικα, in *Antiquity*, feasts or sacrifices celebrated at Athens, in honour of Bacchus.

The *Phallica* were instituted on the following occasion: one Pegasus, a citizen of Eleutheris, having carried some statues of Bacchus to Athens, drew on himself the laughter and contempt of the Athenians. Soon after this, the people were seized with an epidemic disease; and, upon consulting the oracle how to get free of it, were answered, that there was no way but to receive Bacchus in pomp: they did it, and thus instituted the *Phallica*; wherein, besides the statues and trophies of the god, they bore figures of the parts affected, tied to thyrsi.

PHALLOPHORI, φαλλοφοροι, in *Antiquity*, a name given at Sicyon to certain mimes, who ran about the streets smutted with black, and clothed in sheep skins, bearing baskets full of various herbs, as chervil, branca ursina, violet, ivy, &c.

The word is formed from φαλλος, a *pole*, at the end of which was fastened the figure of a human penis made of leather; and φερω, *I bear*.

They danced in cadence, and were crowned with ivy, in honour of Bacchus; carrying the *phallus* before them as the ensign of their office.

PHALLUS, *stink-horns*, in *Botany*, a genus of the *cryptogamia* class, and *fungi* order; the fungus of which is reticulated on the upper side, and smooth on the lower. There are two species.

PHALLUS *marinus*, a name given by some authors to a species of *cancelli* or *tubuli marini*, found about Amboyna, and called by the French writers *priape* and *arrosoir*. It is an oblong shell, with a large head, which is pierced full of holes; so that it at once resembles the *glans penis*, and the nose of a watering-pot used by gardeners.

PHANATIC, *phanaticus*, commonly written *fanatic*, a visionary; one who fancies or thinks he sees spectres, spirits, apparitions, or other imaginary objects, even when awake; and takes them to be real.

Such are phrenetics, necromancers, hypochondriac persons, lycanthropi, &c. See PHRENSY, HYPOCHONDRIAC, LYCANTHROPY, &c.

Hence the word is also applied to enthusiasts, pretenders to revelation, new lights, prophecies, &c. See FANATIC.

PHANTASM, φαντασμα, *phantasm*, a species of an object perceived by an external sense, and thence retained in the phantasy.

PHANTASTIC, in *Music*. *Phantastic style* is a free, easy manner of composition; proper for instruments. See STYLE.

PHANTASTICAL *colours*, is a denomination given by the Peripatetics to those colours exhibited by the rainbow, or a prism; they erroneously supposing them not to be real colours, but only phantoms, or deceptions of the sight. But many experiments of the moderns, and particularly those of Sir Isaac Newton, demonstrate the contrary, and prove them as real as any other colours in nature. See EMPHATICAL.

PHANTASY, or FANCY, the *imagination*; the second of the powers or faculties of the sensitive or rational soul; by which the species of objects received by the common sense, are retained, recalled, farther examined, and either compounded, or divided.

Others define the *phantasy* to be that internal sense or power, whereby the ideas of absent things are formed, and presented to the mind, as if they were present.

The seat or organ of this sense is vulgarly supposed to be the middle part of the brain; and its objects, all the species communicated to it by the common sense, by the comparing of which it frames infinite others to itself.

In melancholic and mad men this faculty is very strong, representing many extravagant and monstrous things, and framing its images as lively as those of sensation; whence naturally arise the visions and fables with more strength, consistency, and beauty.

In men it is supposed to be subject to reason, but in brutes it has no superior; this being the *ratio brutorum*, or what we call reason in brutes.

The *phantasy* is free from the ligature, or suspension of sleep; witness our dreams, &c.

Some philosophers use the word *phantasy* in a more general signification, viz. for what we usually call *sensus communis*, the *common* SENSE. See IMAGINATION.

PHARAON, the denomination of a game of chance. The

principal rules of this game are, that the banker holds a pack of fifty-two cards; that he draws all the cards one after the other, and lays them down at his right and left hand alternately; that the ponte may at his choice set one or more ſtakes upon one or more cards, either before the banker has begun to draw the cards, or after he has drawn any number of couples; that the banker wins the ſtake of the ponte, when the card of the ponte comes out in an odd place on his right hand, but loſes as much to the ponte when it comes out in an even place on his left hand; that the banker wins half the ponte's ſtake, when it happens to be twice in one couple; that when the card of the ponte being but once in the ſtock, happens to be the laſt, the ponte neither wins nor loſes; and that the card of the ponte being but twice in the ſtock, and the laſt couple containing his card twice, he then loſes his whole ſtake. Mr. De Moivre has ſhewn how to find the gain of the banker in any circumſtance of cards remaining in the ſtock, and of the number of times that the ponte's cards is contained in it. Of this problem he enumerates four caſes; i. e. when the ponte's card is once, twice, three, or four times, in the ſtock.

In the firſt caſe, the gain of the banker is $\frac{1}{n}$, n being the number of cards in the ſtock. In the ſecond caſe, his gain is $\frac{n-2\times y}{n\times n-1}+\frac{2}{n\times n-1}$, or $\frac{y\,n+1}{n\times n-1}$, ſuppoſing $y=\frac{1}{2}$. In the third caſe, his gain is $\frac{3y}{2\times n-1}$, or $\frac{3}{4\times n-1}$, ſuppoſing $y=\frac{1}{2}$. In the fourth caſe, the gain of the banker, or the loſs of the ponte, is $\frac{2n-5}{n-1\times n-3}$, or $\frac{2n-5}{2\times n-1\times n-3}$, ſuppoſing $y=\frac{1}{2}$. Mr. De Moivre has calculated a table, exhibiting this gain or loſs, for any particular circumſtance of the play; and he obſerves, that at this play, the leaſt diſadvantage of the ponte, under the ſame circumſtances of cards remaining in the ſtock, is when the card of the ponte is but twice in it, the next greater when three times, the next when once, and the greateſt when four times. He has alſo demonſtrated, that the whole gain *per cent.* of the banker, upon all the money that is adventured at this game, is 2*l.* 19*s.* 10*d.* De Moivre's Doctrine of Chances, p. 77, &c. p. 105, &c. See BASSETTE.

PHARI, among the *Ancients*, a kind of candleſtick. See BRANCH.

PHARICUM, the name of a famous poiſon among the ancients: it was ſaid to be compoſed of many ingredients, but we know nothing of it at this time.

PHARISEES, a celebrated ſect among the ancient Jews; ſo called, ſay ſome, becauſe ſeparated from the reſt by the auſterity of their life, and by their profeſſing a greater degree of holineſs, and a more religious obſervation of the law.

This is the import of the word פרושים, in the Hebrew, or rather Chaldee tongue; whence is formed the Greek Φαρισαιος, and the Latin *Phariſæus*. St. Jerom, and ſeveral of the rabbins, maintain this etymology; which is very agreeable to the ſtate and character of the *Phariſees*; who were not only diſtinguiſhed from the reſt by their manner of life, but by their habit. However, others, with leſs probability, have derived the name from פרש, *expoſuit*, becauſe the *Phariſees* were in the higheſt reputation for expounding the law.

It is very difficult to fix the preciſe origin of the *Phariſees*. The Jeſuit Serrarius places their firſt riſe about the time of *Eſdras*; becauſe it was then that the Jews firſt began to have interpreters of their traditions. Maldonat, on the other hand, will not have this ſect to have ariſen among the Jews, till a little before the time of Chriſt. Others, perhaps with more probability, refer the origin of the *Phariſees* to the time of the Maccabees.

Dr. Lightfoot thinks, that *Phariſaiſm* roſe up gradually, from a period which he does not aſſign, to the maturity of a ſect. It is certain, from the account given by Joſephus, that in the time of John Hyrcanus, the high prieſt and prince of the Aſmonean line, about a hundred and eight years before Chriſt, the ſect was not only formed, but made a conſiderable figure; and that it had advanced to a high degree of popularity and power about eighty years before Chriſt. Joſ. Ant. lib. xiii. cap. 10 § 5, 6. cap. 15. § 5. & cap. 16. § 1. According to Baſnage, Hiſt. of the Jews, book ii. cap. 9. § 2. one Ariſtobulus, an Alexandrian Jew, and a Peripatetic philoſopher, who flouriſhed about a hundred and twenty-five years before Chriſt, and wrote ſome allegorical commentaries on the Scripture, was the author of thoſe traditions, by an adherence to which the *Phariſees* were principally diſtinguiſhed from other ſects.

Be this as it will, *Phariſaiſm* is ſtill the prevailing doctrine in the Jewiſh religion; that vaſt number of traditions in the Talmud, which bear ſo great a ſway among the Jews, coming all from the *Phariſees*, which they aſcribed to God, and received as of equal authority with the ſacred writings. See MISCHNA.

Joſephus, who deſcribes their dogmata, ſays, that they attributed all to deſtiny, and to God; ſo, however, as not to deprive man of his free agency; which Sixtus of Sienna thus explains: the *Phariſees* believed, that all things were done by deſtiny, i. e. with God's foreknowledge, and in conſequence of his immutable decree; the will of man ſtill remaining free and unaffected: *Fatis, hoc eſt, Dei præſcientiæ, & immobili decreto, omnia geri; manente tamen libero humanæ libertatis aſſenſu.*

They owned the immortality of the ſoul, a reſurrection, and a future ſtate; but they admitted, at the ſame time, as ſome have ſuppoſed, a kind of metempſychoſis, or tranſmigration of ſouls. They alſo held the doctrine of angels, and ſeparate human ſpirits.

The *Phariſees* were great ſticklers for the allegorical or myſtical ſenſe of the Scriptures; whence moſt of the converts made to Chriſtianity among the Jews were of the number of the *Phariſees*.

In effect, the *Phariſees* were in every thing directly oppoſite to the Sadducees.

PHARMACEUTICA, Φαρμακευτικη, that part of phyſic which directs the preparation and application of medicines. See PHARMACY.

PHARMACI, Φαρμακοι, among the Greeks, an appellation uſed for two perſons who were employed in the LUSTRATION or purification of cities.

Theſe were two men, according to ſome; but others ſuppoſe them to have been a man and woman, to repreſent the male and female ſex; for each of which they offered a ſacrifice. It was uſual for the man to carry about his mock figs, called συκαζες, of a blackiſh colour; and the woman ſuch as were white. Pott. Archæol. Græc. tom. i. p. 400, ſeq.

PHARMACIA, Φαρμακια, in *Antiquity*, denotes the art of effecting ſtrange and wonderful things, by means of medicated and enchanted compoſitions of herbs, minerals, &c. Theſe things themſelves were called *pharmaca*, ſome of which, being taken inwardly, were ſaid to cauſe blindneſs, madneſs, love, &c. Such were the medicaments by which Circe transformed Ulyſſes' ſoldiers; others infected by touch; ſuch was the garment Medea ſent to Creuſa; others ſpread their venom afar off, and operated upon perſons at a great diſtance.

There were alſo *pharmaca ſalutaria*, Φαρμακα σωτηρια, which were amulets againſt the former; ſuch was the herb moly, which preſerved Ulyſſes from Circe's enchantments; the laurel, the ſallow-tree, the rhamnus or Chriſt-thorn, ſlea-bane, the jaſper-ſtone, and many others mentioned by Albertus Magnus, and Orpheus, in his book De Lapillis. Pott. Archæol. Græc. lib. ii. cap. 18. tom. i. p. 353. See AMULET.

PHARMACITIS *terra*, in the *Materia Medica*, a name which ſome authors have given to the common ANTHELITES, or canal-coal.

PHARMACOCHEMIA, a term uſed to expreſs that part of the chemical art which treats of the preparation of medicines.

It is thus called by way of diſtinction from that chemiſtry, which is wholly employed about the tranſmutation of metals by means of the philoſopher's ſtone; this being called *ſpagirica-chemia*.

PHARMACOLOGY, a treatiſe of medicines, or the art of preparing them, judging of them, &c.

PHARMACOPŒIA, formed from φαρμακον, *remedy*, and ποιεω, *to make*, a diſpenſatory, or a treatiſe deſcribing the preparations of the ſeveral kinds of medicines, with their uſes, manner of application, &c.

We have various *pharmacopœiæ*; as thoſe of Bauderon, Quercetan, Zwelfer, Charas, Bates, Salmon, Lemery, &c. The laſteſt, and moſt in eſteem, are the Edinburgh and London diſpenſatories; but the moſt univerſal is Quincy's *Pharmacopœia*.

PHARMACOPOLA, or PHARMACOPOLIST, an *apothecary*; or a perſon who prepares and ſells medicines. See APOTHECARY.

The word is ſeldom uſed but by way of ridicule. It is formed from φαρμακον, and πωλεω, *to ſell*. See Horace, Satire 2. lib. i. verſ. 1.

PHARMACUM, Φαρμακον, a medicament, or medicine; whether of a ſalutary, or poiſonous quality.

PHARMACY, Φαρμακια, derived from φαρμακον, *remedy*, that branch of medicine, which teaches the choice, preparation, and mixture of medicines.

Moſt of the natural bodies being ſome way or other employed as ſubjects of *pharmacy*, the materia medica is extremely large, and its operations various. Its materials in the earlieſt ages, indeed, were very few, and the

ways of managing them very simple: subjects afterwards multiplied, operations increased, and at present we seem abundantly stocked with both simple and compound medicines.

Diseases must have been very early, if the first inhabitants of the earth experienced the same changes of seasons, breathed the same kind of air, and used a like kind of diet and regimen of life with ourselves; but soon after the disease attacks, the patient seeks a remedy; and this appears to have been the foundation of *pharmacy* in different parts of the world.

Experiments being thus multiplied, and the preparations of simples better made, *pharmacy* became at length an art. Hippocrates, however, when he came to compile a kind of system of physic from the observations of antiquity, described but few, and those generally simple.

Succeeding physicians then enlarged the MATERIA *medica*; Galen considerable swelled the catalogue, and the Arabians much more; and when learning began to revive in Europe, the materia medica was again enlarged, and great changes wrought upon it by chemistry.

The art of *pharmacy* must be considered under the management of physicians, apothecaries, trading chemists, and druggists. To the physician it belongs to direct the medicines, and to give the rules of extracting and managing the simples. To the apothecary belongs the reduction of the materia medica into certain forms of medicines, according to the direction of the physician. And the design of trading chemists, and druggists, is to furnish medicinal matters to the apothecary, who cannot always detect an artificial counterfeit, or a dexterous sophistication; and perhaps many remedies, well designed by the physician, have failed, or had mischievous effects on this account. Shaw's Lecture, p. 105

Pharmacy is divided into Galenical and chemical.

PHARMACY, *Galenical*, called also simply *pharmacy*, is that derived to us from the ancients; consisting in the knowledge and management of the several parts of the materia medica, now in the hands of the apothecaries. See GALENIC.

PHARMACY, *chemical*, called also *spagirical* and *hermetical*, is that introduced by Paracelsus, who calls it *ars dissolutoria*, consisting in the resolving of mixed bodies into their component parts, in order to separate the useless and ill, and collect and exalt the good. See CHYMISTRY.

One of the chief obstacles in the way of the improvement of physic, is the physicians neglecting of *pharmacy*; simples, vulgar, familiar, easily prepared, and readily procured, Pliny well observes, were the only remedies intended by nature: when fraud was got into the world, and men began to live by their wits, shops were soon set up, and life offered every man to sale. Soon after this, innumerable compositions, and endless, inexplicable mixtures, were cried up; the products of Arabia and India were crouded into a draught; and a plaster for a little ulcer fetched from the Red Sea; whereas the proper remedies are those the poor every day meet with. Hist. Nat. lib. xxix. cap. 1.

PHARMACY, *counsellors in*. See CHARACTER.

PHARMUTHI, in the *Egyptian Chronology*, one of the months of their year, which answered to the month of April among the Romans.

PHARNACEUM, in *Botany*, a genus of the *pentandria trigynia* class. Its characters are, that the empalement is compofed of five leaves; it has no corolla; and the fruit is a three-celled, polyfpermous capfule. There are four fpecies.

PHAROS, *pharus*, a *light-house*, a pile raised near a port, where a fire is kept burning in the night, to guide and direct veffels near at hand.

The *pharos* of Alexandria, built in a fmall iſland at the mouth of the Nile, was anciently very famous, inſomuch as to communicate its name to all the reſt. It was fo magnificent a ſtructure, being built by the famed architect Soſtratus, a native of Cnidos, or, as ſome ſay, by Deiphanes, the father of Soſtratus, that it coſt Ptolemy Philadelphus eight hundred talents. It had ſeveral ſtories raiſed one over another, adorned with columns, balluſtrades, galleries of the fineſt marble and workmanſhip, to which, ſome add, that the architect had contrived to faſten ſome looking-glaſſes, ſo artificially againſt the higheſt galleries, that one could ſee in them all the ſhips that ſailed on the ſea for a great way; inſtead of which noble ſtructure, one ſees now only a kind of irregular caſtle, without ditches or outworks of any ſtrength, the whole being accommodated to the inequality of the ground on which it ſtands, and which it ſeems is no higher than that which it ſhould command. Out of the midſt of this clumſey building riſes a tower, which ſerves for a light-houſe, but which hath nothing of the beauty and grandeur of the old one. The COLOSSUS of Rhodes alſo ſerved as a *pharos*.

Ozanam ſays, *pharos* anciently ſignified a ſtreight; as the *pharos* or *pharo* of Meſſina. See LIGHT-*houſe*.

PHARSANG, or PARASANG. See PARASANG.

PHARUS, in *Botany*, a genus of the *monoecia hexandria* claſs. Its characters are, that it has male and female flowers; the empalement of the male is a glume, with two valves, and a ſingle flower, and the corolla is a bivalve glume; the empalement of the female flower is the ſame with that of the other; the corolla is a ſingle valved, long glume; it has one ſeed. There is only one ſpecies.

PHARYNGÆUM *ſal*, a name given by authors to an artificial ſalt, of uſe in the quinſey, and caſes of the like kind, when the *pharynx*, or fauces, are incommoded by a diſcharge of ſerous or other humours.

It is prepared of cream of tartar and nitre, each an ounce, with half an ounce of burnt alum; all theſe are to be diſſolved in vinegar, and coagulated according to art. This ſalt mixed with honey, and diſſolved in plantain water, makes an excellent gargle.

PHARYNX, Φαρυγξ, in *Anatomy*, the upper opening of the œſophagus or gullet, ſituate at the bottom of the mouth; and called alſo the *fauces*.

The *pharynx* is that part more particularly called the *gula*, or gullet; in which the action of deglutition commences, and where it is chiefly performed.

The *pharynx* is a muſcular and glandular bag, the outer ſurface of which is cloſely joined to the inner ſurface of all that ſpace which is at the bottom of the mouth, behind the poſterior nares, uvula, and larynx, and which reaches from the anterior apophyſis of the os occipitis to the œſophagus, which is the continuation of the *pharynx*. It may be divided into three parts; one ſuperior, which is the arch of the *pharynx*; one middle, which is the body or great cavity; and one inferior, which is the bottom, narrow portion, or ſphincter. There are in it likewiſe three openings, that of the arch, towards the nares, that of the body, towards the mouth, and that of the bottom towards the œſophagus.

It is aſſiſted by three pair of muſcles, which principally compoſe the *pharynx*. The firſt, called the *ſtylopharyngæus*, ſerves to draw up and dilate the *pharynx*; the ſecond, the *pterygopharyngæus*, ſerves to conſtringe it; the third, which is called the *œſophagæus*, ſerves to cloſe it. See each under its proper article.

The muſcles of the *pharynx* are reduced by Mr. Whiſlow to three general claſſes, with regard to their inſertions: the firſt claſs comprehends thoſe which are inſerted in the baſe of the cranium; and they are the CEPHALO-*pharyngæi*, the PETRO-*pharyngæi*, the SPHENO-*pharyngæi*, the PTERYGO-*pharyngæi*, and STYLO-*pharyngæi*. The ſecond claſs includes thoſe which are inſerted towards the mouth; viz. the PERYSTAPHILO-*pharyngæi*, the GLOSSO-*pharyngæi*, the HYPERO-*pharyngæi*, which is a general denomination for thoſe on each ſide that are inſerted in the os hyoides, and may be reckoned three pairs, the *baſio-pharyngæi*, *kerato-pharyngæi minores*, and the *majores*; and the GENIO-*pharyngæi*. The third claſs comprehends thoſe inſerted in the lateral parts of the larynx, viz. the SYNDESMO-*pharyngæi*, the THYRO-*pharyngæi*, the CRICO-*pharyngæi*, the OESOPHAGÆUS, and the ADENO-*pharyngæus*.

The particular uſes of all theſe muſcles are very difficultly determined. It is certain, that thoſe of the middle and lower portions of the *pharynx* ſerve chiefly for deglutition; thoſe of the upper portion, and ſome of thoſe of the middle portion, may, among other functions, be uſeful in modifying the voice, according to the opinion of M. Sauvorini. Whiſlow.

PHASCUM, in *Botany*, a genus of the claſs of *cryptogamia*, and order of *muſci*, or moſſes. Its characters are, that the anthera is covered, and guarded at the margin by parallel briſtles, and that the calyptra, or veil, is ſmall. There are four ſpecies.

PHASEOLUS, in *Botany*. See *Kidney*-BEAN.

PHASES, Φασεις, formed from Φαινω, *I appear*, in *Aſtronomy*, the ſeveral appearances, or quantities of illumination of the moon, Venus, Mercury, and the other planets; or the ſeveral manners wherein they appear illuminated by the ſun.

The variety of *phaſes* in the moon is very remarkable: ſometimes ſhe increaſes, ſometimes wanes, ſometimes is bent into horns, and again appears like a ſemicircle; at other times ſhe is gibbous, and preſently again reſumes a full circular face. For the theory of the *ſame phaſes*, ſee MOON.

As to the *phaſes* of Venus, the naked eye does not diſcover any diverſity in them; but the teleſcope does: Copernicus anciently propheſied, that after-ages would find, that Venus underwent all the changes of the moon; which prophecy was firſt fulfilled by Galileo, who, di-

feeling his telescope to Venus, observed her *phases* to emulate those of the moon; being sometimes full, sometimes horned, and sometimes gibbous.

Mercury also does the same; all the difference between these and those of the moon, is, that when these are full, the sun is between them and us; whereas, when the moon is full, we are between her and the sun.

Saturn puzzled the astronomers a long time with his strange variety of *phases*; Hevelius and others found him, 1. Monospherical. 2. Trispherical. 3. Spherico-ansated. 4. Elliptico-ansated. 5. Spherico-cuspidated. But Huygens shews, that these monstrous *phases* were principally owing to the imperfection of their telescopes. That great author, assisted by the best telescopes, noted three principal *phases*; viz. Jan. 16, 1656, he was round; Octob. 13, brachiated; and Decem. 17, 1657, ansated. See SATURN.

PHASES *of comets*. See COMET.

To determine the PHASES *of an eclipse for any given time.*—Find the moon's place in her visible way for that moment; and thence, as a centre, with the interval of the moon's semidiameter, describe a circle. Find in like manner the sun's place in the ecliptic, and thence, with the semidiameter of the sun, describe another circle; the intersection of the two circles shews the *phases* of the eclipse, the quantity of obscuration, and the position of the cusps or horns.

PHASIANUS, in *Ornithology*. See PHEASANT.

PHASMATA, in *Physiology*, certain appearances arising from the various tinctures of the clouds by the rays of the heavenly luminaries, especially the sun and moon.

These are infinitely diversified by the different figures and situations of the clouds, and the appulses of the rays of light; and, together with the occasional flashings and shootings of different meteors, they have, no doubt, occasioned those prodigies of armies fighting in the air, &c. of which we have such frequent accounts in most sorts of writers. Vide 2 Maccab. xi. 8. Melancth. Meteor. 2 Shel. de Comet. ann. 1618.

Kircher, and his imitator Schottus, have erroneously endeavoured to explain the phenomenon from the reflection of terrestrial objects made on opake and congealed clouds in the middle region of the air, which, according to them, have the effect of a mirror. So that, according to these authors, the armies pretended by several historians to have been seen in the skies were no other than the reflection of the like armies placed on some part of the earth. Vide Hist. Acad. Roy. Scienc. ann. 1726. p. 405, & seq.

PHASSACHATES, in the *Natural History of the Ancients*, the name of a species of *agate*, which, in its different appearances, they sometimes called also LEUCACHATES and PERILEUCOS. It is found in the East Indies, and in Bohemia, and some other parts of Europe.

PHAUSINGES, a name given by the ancients to red circles on the legs, occasioned by fire: it is by some also extended to several other spots and blemishes on the skin.

PHEANITIDES, in *Natural History*, a name given by some to the stone called *empnumites*; it was of the nature of our spurry incrustations on the roofs of subterraneous caverns. It was supposed to have great virtues in promoting delivery, and was given to women when they fell in labour.

PHEASANT, *phasianus*, in *Ornithology*, a genus of birds of the gallinæ order.

The distinguishing characteristic of this genus of birds, is, that the area or space about the eyes is naked, and that they have no wattles.

The species are these: 1. The common *pheasant*, with a blackish purple-coloured breast. 2. The red, or scarlet-breasted *pheasant*: this is nearly of the size of the common *pheasant*, and its breast is of a high scarlet, and the belly red, but not so bright. 3. The East India *pheasant*: this is an extremely beautiful bird, the whole body of which is variegated with a profusion of the brightest colours, yellow, red, bluish green, and almost every other tinge.

Linnæus enumerates three other species; viz. the motmot, or brown *pheasant* of Guinea; the nythemerus, or white *pheasant* of China; and the argus, or yellow *pheasant*, spotted with black, of Chinese Tartary, besides several varieties of the common sort. *Pheasants* were first brought into Europe from the banks of the Phasis, a river of Colchis. Martial, lib. xiii. ep. 72.

The *pheasant* is so nearly allied to our common poultry, that it would naturally appear a very easy thing to breed them up from young; but the proper food of them is not sufficiently enquired into. Though they eat corn when full grown and in health, yet they have recourse, in their young state, and when sick, to another sort of food, preying on several insects, and that in a very voracious manner.

The young *pheasants* and partridges prey upon ants; and they will never succeed with us, if they have not a proper quantity of ants to have recourse to, as soon as they leave their roost in a morning. When musty corn, or want of due care in cleaning their houses, has made them sick, a repast of ants will often recover them. When that fails, they may be offered millepedes or earwigs, or both together, which will always do much better than either singly. To this medicine must be added a proper care that their common food of corn be very sweet, their habitation be kept nicely clean, and their water shifted twice a day. They must not be let out of the house in a morning till the dew is off the ground; and after sunset they must be immediately taken in again: in the heat of the day they must be allowed to bask in the sun in a dry sandy place. With these regulations, the birds of this kind will succeed much better than they usually do. The *pheasant* is a bird of a sullen disposition; and when the coupling time is over, these are seldom found more than one in a place. Phil. Transf. N° 23.

The way of taking *pheasants* is, first, to be acquainted with their haunts and breeding-places; which are usually young, thick, and well-grown coppices, free from the disturbances of cattle, and having no path-way through them; for the *pheasant* is an extremely timorous bird. When the haunts are discovered, the next thing to be attempted is, to find where the eye or brood is. In order to this, it is to be considered, that the *pheasants* comes out of the wood three times a day to feed in green corn, fresh pastures, or the like places. The times of coming out are in the morning soon after sun-rise, at noon, and at sun-set. The sides of the wood where they are supposed to come out are to be carefully watched on this occasion, and the young ones will be seen following the female just as a flock of chickens follow the hen. The wood may be also well watched in the evenings, and the noise of the cock and hen calling the young ones together will soon be heard; and the sportsman is on this occasion to get as near as he can to the place, and being very still and silent be may observe their numbers and disposition, and learn how to spread his nets so as to take the whole brood with great ease; but if his least motion when near them discover him, they will all take to their legs, and run to a great distance; they seldom rise on the wing, except very close frighted indeed. Practice will make some people so expert at imitating the voice of the old *pheasant*, that he will be able to call the young ones together to any place that he pleases, when the haunts are once found out, and by this means they are easily led into the nets.

The best time for using the call is in the morning or evening; and the note imitated should be that by which the old ones call them out to feed; but by learning to imitate the other notes they will be brought together at any time of the day. The sportsman who can make this call must shelter himself in some close place, and begin by very softly making the note; then, if none are near enough to be within hearing, he is to raise it to more and more loudness, and at length he will be answered as loud, if any are within hearing, though at a considerable distance; whereas, if he should set up the call too loud at first, and any of the birds should happen to be very near, they would be frighted away.

As soon as a *pheasant* answers, the sportsman is to creep nearer and nearer, still calling, though not so loud; he will still be answered, till at length he will be led by the bird's voice within sight of it. As soon as this is the case, he is to spread his net, and then begin to call again, keeping in some close and well sheltered place behind the net; in this place he is to call till the bird approaches; and when he has drawn it under the net, he is to appear suddenly, and the bird, rising up, will be caught in the net.

Another method of taking *pheasants* much quicker than by this means is, the having a live cock *pheasant* to use as a stale: this bird is to be fixed under the net, and by his crowing he will soon entice others in. The sportsman must be concealed; and as soon as another *pheasant* comes in, he is to draw the net over him. Many people have a method of taking *pheasants* in springes or horse-hair snares: the succeeding in this depends on the carefully searching out their haunts, and the places by which they go out of the woods into the fields. When these are found, a peg is to be fixed in the ground at each, and at each peg two springes are to be laid open; the one to take in the legs, the other the head. As soon as the springes are set, the sportsman is to go into the woods, and getting behind the birds, he is to fright them with some little noise, such as shall not be enough to raise them to the wing, but only to set them a-running. They will naturally make their way out of the wood, through their accustomed passes, and be then caught in the springes.

There is another method of taking these birds in the winter, provided that there is no snow. This is to be done

done with a net made like a casting net, but with the meshes much wider; they may be five inches wide. Some peas or wheat are to be taken out; and the path of the *pheasants* being discovered, which may easily be done by their dung, a part or thereabout of corn is to be thrown down in the path in a place marked, so that the sportsman can come to it again. This is to be done for several days, till at length the *pheasants* are expecting it every day regularly; and all the birds of this kind that frequent the place are brought together to feed there, and then the net is to be fixed over the place; its top being tied up to some bough of a tree, and its bottom fixed down all around, except in one place, where the walk of the *pheasants* lies. In this place it is to be raised in form of an arch, and the entrance is to be lined with several rods of hazel; the thick ends of which are to be tied to the net, and the thin ones let into the space covered by it; and thus the *pheasants* will easily get in by parting the small ends of the sticks, as fish into a wheel, but they will not easily get out again. The nets are to be dyed of a russet colour, by laying them in a tan-pit; and they must, when planted for this purpose, be covered with boughs, so that the birds do not discover them, and then they will easily run into them, and be all taken at once.

PHEASANT'S *eye, flos Adonis*, in *Botany*, a genus of the *polyandria polygynia* class. Its characters are these: the flower has a five-leaved empalement, and five, twelve, or fourteen petals, without any nectaria, which expand in form of a rose; in the centre there are many germina collected in a head, attended by a great number of short stamina, crowned by oblong, inflexed summits; after the flower is past, the germina become so many naked seeds, closely adhering to the pedicle, and forming an obtuse spike. Miller enumerates three, and Linnæus four species.

The common Adonis grows naturally on the sides of the river Medway in Kent; and for some years past great quantities have been sold in London under the name of red Morocco.

PHEASANT'S *eye pink*. See PINK.

PHEASANT, *sea*. See *Pintail* DUCK.

PHECOS, in *Botany*, a name used by some authors for the *stapitaria*, or *water-arrow-head*.

PHELLANDRIUM, in *Botany*, a genus of the *pentandria digynia* class. Its characters are, that the flosculi of the disc are small, and that the fruit is ovated, smooth, and crowned with a perianthium and pistil. There are two species.

PHELLOS, in *Botany*, a name used by some authors for the cork-tree.

PHELLOS, Φελλος, in *Antiquity*, a festival in honour of Bacchus, being a preparative to the DIONYSIA.

PHENGITES, in the *Natural History of the Ancients*, the name of a very beautiful species of alabaster. It is a very rude and irregular mass, very shattery and friable, yet of a brightness superior to that of most of the other marbles, and excelling them all in transparence; it is in colour of an agreeable pale, yellowish, white, or honey colour; the yellowish is more intense in some places than in others, and sometimes makes an obscure resemblance of veins. It is very weak and brittle in the mass, and when reduced to small pieces, is easily crumbled between the fingers into loose, but considerably large angular pieces, some perfect, others complex, irregular, or mutilated, and all approaching to a flat shape.

The ancients were very fond of this species in their public buildings; and the Temple of Fortune, built wholly of it, has long been famous. Its great beauty is its transparence, from which alone this temple was perfectly light when the doors were shut, though it was built without a window, and had no other light but what was transmitted through the stone its walls were built with. It was anciently found in Cappadocia, and is still plentiful there: we have it also in Germany and France, and in our own kingdom in Derbyshire, and some other counties. It takes an excellent polish, and is very fit for ornamental works, where there is no great strength required. Hill's Hist. of Foss. p. 490. See GLASS.

PHEONS, in *Heraldry*, the barbed heads of darts, arrows, or other weapons.

Pheons are represented as in *Tab.* II. *Herald. fig.* 79.—Sable, a fesse ermine between three *pheons*, by the name of Egerton.

PHEOS, in *Botany*, a name given by Theophrastus, Dioscorides, and others, to a plant used by the fullers in dressing their cloths, and of which there were two kinds, a smaller, called simply *pheos*, and a larger, called *hippopheos*.

The name of this plant is sometimes written *phleos*; and it is by that confounded with a kind of marsh cudweed, or *gnaphalium*, called also by that name; but it may be always found which of the two plants an author means, by observing the sense in which the word is used, and the use to which the plant was put. The *phleos*, properly so called, that is, the cudweed, was used to stuff beds and other such things, and to pack up with earthen vessels to prevent their breaking; but the *pheos*, improperly called *phleos*, only about cloths; this was, however, also called *flæbe* and *exophon*.

PHEREPHATTIA, Φερεφαττια, in *Antiquity*, a festival at Cyzicum, wherein a black heifer was sacrificed to Pherephatta or Proserpine.

PHIAL, *phiala*, formed of φιαλη, which signifies the same, a small thin glass bottle, popularly called a *vial*.

PHIAL, *Leyden*. See LEYDEN.

PHIDITIA, or PHILITIA, in *Antiquity*, feasts instituted by Lycurgus, and celebrated with great frugality at Lacedæmon.

The *Phiditia* were held in the public places, and in the open air: rich and poor assisted at them alike, and on the same footing; their design being to keep up peace, friendship, and a good understanding and equality among all the citizens, great and small. Bernegger says, they who attended at this feast brought each a bushel of flour, eight measures of wine, called chorus, and five minæ of cheese, and as much figs.

The *Phiditia* of the Greeks were much the same with the CHARITIA at Rome.

PHILA, in *Mythology*, one of the attributes of Venus, which distinguishes her as the mother of love, from φιλεω, *to love*.

PHILADELPHIA, in *Antiquity*, were games instituted at Sardis, to celebrate the union of Caracalla and Geta, the sons of Septimius Severus.

PHILADELPHIA *stones*, a name given by some authors to what are called by others *Christian's bones*, found in the walls of that city. It is a common error, that these walls are built of bones, and the tradition of the country is, that when the Turks took the place they fortified it for themselves, and built their walls of the bones of the Christians whom they killed there. Dr. Smyth, in one of his epistles, mentions this wall as an instance of the Turkish barbarity; but this is an idle opinion, what passes for bone being only a loose and porous stone of the spurry kind, found in an old aqueduct, which is filled in the wall. Sir Paul Rycaut brought home pieces of these stones, which he also supposed to have been bones, but on examination they proved to be no other than various bodies, chiefly vegetable, incrusted over and preserved in a spar of the nature of that which forms incrustations in Knaresborough spring, and other places with us. These bodies are often cemented together in great numbers by this matter, and their true shape lost in the congeries, till a diligent and judicious eye traces them regularly.

PHILADELPHIAN *Society*, in *Ecclesiastical History*, an obscure and inconsiderable society of mystics, formed towards the close of the last century by an English female fanatic, named Jane Leadley, who seduced by her visions, predictions, and doctrines, several disciples, among whom were some persons of learning. This woman apprehended, that all dissensions among Christians would cease, and the kingdom of the Redeemer become a scene of charity and felicity, if Christians, without regarding the forms of doctrine or discipline that distinguish particular communions, would all join in committing their souls to the care of the internal guide, to be instructed, governed, and formed, by his divine impulse and suggestions. Nay, the pretended a divine commission to proclaim the approach of this glorious communion of saints; and imagined that the society established by herself was the true kingdom of Christ. One of her leading doctrines was, that of the final restoration of all intelligent beings to perfection and happiness.

PHILADELPHUS, φιλαδελφος, in *Antiquity*, a title or surname, borne by several ancient kings; formed from the Greek φιλος, *friend, lover*, and αδελφος, *brother*; q. d. one who loves his brother, or brethren.

Ptolemy *Philadelphus* erected a library at Alexandria, and furnished it with four hundred thousand, others say with seven hundred thousand volumes, by the advice, and with the assistance, of Demetrius Phalereus. See ALEXANDRIAN *Library*.

It was the same *Philadelphus* that procured the Greek version of the books of Moses, called the SEPTUAGINT.

Father Chamillart has a medal of the queen of Comagene, which bears the title of *Philadelpho*, without any other name. M. Vaillant tells us, that Philip king of Syria had also the title *Philadelphus*.

PHILADELPHUS, *mock orange*, or *pipe-tree*, in *Botany*, a genus of the *icosandria monogynia* class. Its characters are, that it hath a permanent empalement of one leaf, cut into five acute parts; it hath four or five roundish petals, which spread open; the germen is situated under the flower, supporting a slender style, divided into four parts, each being crowned by a single stigma; the ger-

ten afterwards becomes an oval, scale-pointed capsule, having four or five cells, which are filled with small oblong seeds. Linnæus reckons two, and Miller three species.

PHILANDER, in *Zoology*. See DIDELPHIS and OPOSSUM.

PHILANTHROPOS, in *Botany*, a name used by some authors for the common *sparrow, clivers*, or *goose-grass*.

PHILANTHROPY, Φιλανθρωπια, *love of mankind*, a general benevolence towards the species.

PHILARMONICI, is the denomination of a literary society established at Verona in 1543. See ACADEMY.

PHILAUTIA, Φιλαυτια, formed from φιλος, *amicus*, and αυτος, *ipse*, in the *Schools*, SELF-LOVE, a vicious fondness and complaisance for a man's self.

PHILELIA, the name of a song among the ancient Greeks, in honour of Apollo. Athenæus, lib. xiv. cap. 3.

PHILETERIUM, in *Botany*, a name used by some authors for the *hoben album*, the common white-flowered bladder-campion, called *white bin*.

PHILIPPICS, *Philippicæ, Φιλιππικοι λογοι*, in *Literature*, a name given to the orations of Demosthenes against Philip king of Macedon.

The *Philippics* are esteemed the master-pieces of that great orator: Longinus quotes abundance of instances of the sublime from them; and points out a thousand latent beauties therein. In effect, that pathetic wherein Demosthenes excelled, the frequent interrogations and apostrophes wherewith he attacked the indolence of the Athenians, where could they be better employed? How much delicacy soever there be in the oration against Leptines, the *Philippics* have yet the advantage over it, were it only on account of the subject, which gives Demosthenes so fair a field to display his chief talent, we mean, with Longinus, that of moving and astonishing.

Dionysius Halicarnassæus ranks the oration on the Halonese among the *Philippics*, and places it the eighth in order; but though the authority of that great critic be of no small weight, yet that force and majesty, wherein Cicero characterizes the *Philippics* of Demosthenes, seem to exclude the oration on the Halonese out of the number; and authorize the almost universal opinion of the learned, who reject it as spurious.

Libanius, Photius, and others, but above all the languidness of the style, and the lowness of the expressions, which reign throughout the whole, father it on Hegesippus.

PHILIPPIC is also applied to the fourteen orations of Cicero against Marc Antony. It was Cicero himself that gave them this title in his epistles to Brutus; and posterity have found it so just, that it has been perpetuated to our times.

Juvenal, Sat. x. calls the second the *divine Philippic*, and witnesses it to be of great fame, *conspicua divina Philippica fama*. That orator's intiding his last and most valued orations after the *Philippics* of Demosthenes shews the high opinion he had of them.

Cicero's *Philippics* cost him his life; Marc Antony having been so irritated with them, that when he arrived at the triumvirate, he procured Cicero's murder, cut off his head, and stuck it up in the very place whence the orator had delivered the *Philippics*.

PHILIPPISTS, a sect or party among the Lutherans; the followers of Philip Melancthon.

That reformer having strenuously opposed the the UBIQUISTS, who arose in his time; and the dispute growing still hotter after his death; the university of Watemberg, who espoused Melancthon's opinion, were called, by the Flacians, who attacked it, *Philippists*.

PHILTRA. See PHILTRUM.

PHILTRERS, or PHILTRERES. See PHLEGM.

PHILYREA. See *Mock* PRIVET.

PHILO, a term originally Greek, formed of φιλος, *amicus, friend, or lover*; now used in composition in several words in our language: as,

PHILELEUTHERUS, Φιλελευθερος, formed of φιλος, and ελευθερος, *free*, a lover of liberty.

PHILOLAUS, formed of Φιλος, and λαος, *people*, in *Mythology*, a denomination under which Esculapius was honoured in a temple at Afopus, in Laconia.

PHILOLOGY, Φιλολογια, formed from φιλος and λογος, *lover of discourse*, a science, or rather assemblage of several sciences, consisting of grammar, rhetoric, poesy, antiquities, history, and criticism.

Philology is a kind of universal literature, conversant about all the sciences, &c. their rise, progress, authors who have cultivated them, &c.

Philology makes what the French call the *belles lettres*. In the universities it is also called *humanities*, or *humaniores literæ*.

Anciently, *philology* was only a part of grammar.

Eratosthenes, library-keeper at Alexandria, was the first who bore the splendid title of *Philologus*, according to Suetonius; or that of *critic*, according to Clemens Alexandrinus. He lived under Ptolemy Philadelphus, and died in the 140th Olympiad.

PHILOMATHES, Φιλομαθης, formed from φιλος, *lover*, and μανθανω, *I learn*, a lover of learning or science.

PHILONIUM, in *Pharmacy*, an opiate, or electary whereof there are two kinds, the Roman, and the Persian.

The Roman, called also the great *philonium*, took its name from the physician Philo, who invented it. It consists of the seeds of henbane, pepper, opium, and other ingredients. It is used to promote sleep, and against colds, colics, &c.

The Persian *philonium* consists of several ingredients, among which are opium, terra sigillata, lapis hæmatites, castor, and saffron. It is used to stop hæmorrhages, dysenteries, &c.

PHILONIUS *Londinensis*, the name by which the medicine commonly called *philonium Romanum*, is called in the late London Dispensatory. The composition is also much altered, as well as the name, and is now ordered to be made thus: take white pepper, ginger, caraway-seeds, of each two ounces, opium six drams, syrup of diacodium, boiled to the consistence of honey, three times the weight of all the rest. The opium is to be dissolved in a little wine, and then mixed with the syrup; after which the powders are to be stirred in, and the whole made into an electary.

PHILOPATOR, Φιλοπατωρ, formed from φιλος, *lover*, and πατηρ, *father*, in *Antiquity*, a title or surname, assumed by several of the kings of Egypt and Syria; importing, lover of one's father.

Ptolemy *Philopator* succeeded Ptolemy Euergetes; and had for his successor Ptolemy Philometor. The Syrians had their Seleucus *Philopator*, Antiochus *Philopator*, &c.

PHILOSEBASTUS, Φιλοσεβαστος, i. e. *a friend of Augustus*, was a title assumed by several princes and cities, as a public testimony of their attachment to any emperor. This title is found on the marbles of Cyzicum and in other inscriptions.

PHILOSOPHER, Φιλοσοφος, a person well versed in philosophy; or who makes profession of, or applies himself to, the study of nature and morality.

The sects of *philosophers* are very numerous: and their dogmata or tenets very contradictory.

Helmont, and some of the chemists, denominate themselves *philosophers by fire*.

The alchemists, and adepti, are frequently denominated *the philosophers*, by way of eminence.

PHILOSOPHUS *lotion*. See LOTION.

PHILOSOPHERS *stone*, the greatest object of alchemy, is a long-sought-for preparation, which, when found, is to transmute or exalt impure metals, as tin, lead, and copper, into gold and silver.

Some of the Greek writers, in the fourth and fifth centuries, speak of an art, as being then known, of transmuting the baser metals into gold; and towards the end of the thirteenth century, when the learning of the East had been brought hither by the Arabians, the same pretensions began to spread through Europe. It is supposed that this art, called ALCHEMY, was of Egyptian original; and that, when the ancient Greek philosophers travelled into Egypt, they brought back some of the allegoric language of this Egyptian art, ill understood, which afterwards passed into their mythology. Alchemy was the earliest branch of CHEMISTRY, considered as a philosophical science: in the other parts of chemical knowledge, facts preceded reasoning or speculation; but alchemy was originally speculative. See TRANSMUTATION.

The alchemists supposed the general principles of metals to be chiefly two substances, which they called mercury and sulphur; they apprehended also, that the pure mercurial, sulphureous, or other principles of which they imagined gold to be composed, were contained, separately, in other bodies: and these principles, therefore, they endeavoured to collect, and to concoct and incorporate by long digestions; and by thus conjoining the principles of gold, if they could be so procured and combined, it might be expected that gold would be produced. But the alchemists pretend to a product of a higher order, called the ELIXIR, the medicine for metals, the tincture, the *philosopher's stone*; which, by being projected on a large quantity of any of the inferior metals in fusion, should change them into fine gold; which being laid on a plate of silver, copper, or iron, and moderately heated, should sink into the metal, and change into gold all the parts to which it was applied; which, on being properly heated with pure gold, should change the gold into a substance of the same nature and virtue with itself, so as thus to be susceptible of perpetual multiplication; and which, by continued coction, should have its power more and more exalted, so as to be able to transmute greater

greater and greater quantities of the inferior metals, according to its different degrees of perfection.

There are three ways whereby the alchemists have attempted to arrive at the making of gold: the first, by separation; for it is affirmed, that every metal yet known contains some quantity of gold: only, in most, the quantity is so little, that it will not defray the expence of getting it out.

The second is by maturation; for the alchemists hold mercury to be the basis and matter of all metals; that quicksilver purged from all heterogeneous bodies would be much heavier, denser, and simpler, than the native quicksilver; and that by subtilizing, purifying, and digesting it with much labour, and long operations, it may be converted into pure gold.

This method of maturation is only for mercury: the other metals it is ineffectual for, on two accounts: 1. Because their matter is not pure mercury, but has other heterogeneous bodies adhering to it: and, 2. Because the digestion, whereby mercury is turned into gold, would not succeed in other metals, in regard these had not been long enough in the mines.

Weight is the individual and inimitable character of gold, &c. Now mercury, they say, has ever some impurities in it; and those impurities are lighter than mercury. Could those be purged quite out, as it does not appear to them impossible but they might, mercury would be as heavy as gold; and what is as heavy as gold is gold, or at least might very easily be made gold. See *Fixing of* MERCURY.

The third method is, that of transmuting, or of turning all metals readily into pure gold, by melting them in the fire, and calling a little quantity of a certain preparation into the fused matter; upon which the feces immediately retire, are volatilized and burnt, and so carried off; and the rest of the mass is turned into pure gold. That which works this change in the metals is called the *philosopher's stone*. See TRANSMUTATION.

Whether this third method be possible or not, is very hard to say. We have so many testimonies of it from persons, who on all other occasions speak truth, that it is somewhat hard to say they are guilty of falsehood, even when they say, that they have been masters of the secret. All required is, they say, to do that by art, which nature does in many years and ages. For that as lead and gold do but differ little in weight, therefore there is not much in lead beside mercury and gold. Now, if I had any body which would so agitate all the parts of lead, as to burn all that is not mercury therein; and had also some sulphur to fix the mercury; would not the mass remaining be converted into gold? There is nothing in nature so heavy as lead, gold and mercury alone excepted. It is evident, therefore, there is something in lead that comes very near to gold. But in lead there is also some heterogeneous matter different both from mercury and gold. If now nineteen ounces of lead be dissolved by the fire, and eight ounces be thus destroyed, they argue that we shall have the rest good gold; the ratio of lead to gold being as eleven to nineteen. If then the *philosopher's stone* can purify the mercurial matter in lead, so as that nothing shall remain but the pure mercurial body, and you can fix and coagulate this, by means of sulphur, out of nineteen ounces of lead you will have eleven of gold. Or, if you reduce the lead from eighteen to fourteen, you will then have converted it into mercury; and if you farther purify this mercury to the proper standard, you will have gold, provided you have but a sulphur with which to fix and coagulate it. Such is the foundation of the opinion of the *philosophers stone*; which the alchemists contend to be a most subtile, fixed, concentrated fire, which, as soon as it melts with any metal, does, by a magnetic virtue, immediately unite itself to the mercurial body of the metal, volatilizes and cleanses off all that is impure therein, and leaves nothing but a mass of pure gold. Many frauds and artifices have undoubtedly been practised in this operation; and there might be political reasons why princes and others should encourage those who pretended a power of furnishing this inexhaustible source of wealth: but it would be wrong to censure as impostors, all those who have declared themselves convinced, from their own experiments, of the transmutability of base metals into gold. However there are strong reasons to believe that the authors have been deceived themselves by fallacious appearances. Mr. Boyle gives an account of a process, by which he imagines part of the substance of gold to have been transmuted into silver. See MENSTRUUM *peregrinum*. He also relates a very extraordinary experiment, under the title of the degradation of gold by an anti-elixir, which was published in his own life-time, and since reprinted in 1739. Hence many have been led to conclude in favour of the alchemical doctrine of the transmutability of metals. See an account of this experiment with remarks upon it by Dr. Lewis, in his Commerce of Arts, sect. 12. p. 297, &c.

King Henry VI. granted letters patent to certain persons, who undertook to find out the *philosopher's stone*, and to change other metals into gold, &c. to be free from the penalty of the statute 5 Hen. IV. made against the attempts of chemists of this nature. Par. 34 Hen. VI. 3 Inst. 74.

PHILOSOPHERS *tree*, a chemical preparation, called also ARBOR *Dianæ*, *Diana's tree*.

PHILOSOPHICAL, something that relates to PHILOSOPHY.

PHILOSOPHICAL *æther*. See ÆTHER.

PHILOSOPHICAL *chemistry*. See CHYMISTRY.

PHILOSOPHICAL *criticism*. See CRITICISM.

PHILOSOPHICAL *egg*, among the *Chemists*, is a thin glass body, or bubble, of the shape of an egg, with a long neck or stem; used in digestions.

PHILOSOPHICAL *month*. See MENSTRUUM, and MONTH.

PHILOSOPHICAL *sin*. See SIN.

PHILOSOPHICAL *Transactions*. See TRANSACTIONS.

PHILOSOPHIZING, the act of considering some object of our knowledge, examining its properties, and the phenomena it exhibits, and enquiring into their causes or effects, and the laws thereof; the whole conducted according to the nature and reason of things, and directed to the improvement of knowledge.

PHILOSOPHIZING, *rules of*, *regulæ* PHILOSOPHANDI, 1. established by Sir Isaac Newton, are, 1. That no more causes of a natural effect be admitted than are true, and suffice to account for the phenomena thereof.

This agrees with the sentiments of most philosophers, who hold that nature does nothing in vain; and that it were vain to do that by many things, which might be done by fewer.

2. Natural effects, therefore, of the same kind, proceed from the same causes. Thus, e. gr. the cause of respiration is one and the same in man and brute; the cause of the descent of a stone, the same in Europe as in America; the cause of light the same in culinary fire, and in the sun; and the cause of reflexion the same in the planets as the earth.

3. Those qualities of bodies which are not capable of being heightened, and remitted, and which are found in all bodies where experiments can be made, must be looked on as universal qualities of all bodies.

Thus the extension of body is only perceived by our senses, nor is it perceivable in all bodies: but since it is found in all that we have perception of, it may be affirmed of all. So we find, that several bodies are hard; and argue that the hardness of the whole only arises from the hardness of the parts: whence we infer, that the particles, not only of those bodies which are sensible, but of all others, are likewise hard. Lastly, if all the bodies about the earth gravitate towards the earth, and this according to the quantity of matter in each; and if the moon gravitates towards the earth also, according to its quantity of matter; and the sea again gravitates towards the moon; and all the planets and comets gravitate towards each other; it may be affirmed universally, that all bodies in the creation gravitate towards each other. This rule is the foundation of all natural philosophy.

PHILOSOPHY, Φιλοσοφια, the knowledge or study of nature and morality, founded on reason and experience.

Philosophy owes its name to the modesty of Pythagoras, who refused the title σοφος, *wise*, given to his predecessors, Thales, Pherecydes, &c. as too assuming; and contented himself with the simple appellation of φιλοσοφος, *quasi* φιλος και σοφια, *a friend or lover of wisdom*.

Chauvin rather derives the name from φιλεω, *desire*, or *study*, and σοφια, q. d. *studium sapientiæ*; and says, that Pythagoras, conceiving that the application of the human mind ought rather to be called *study* than *science*, set aside the appellation *wise*, and in lieu thereof took that of *philosopher*. For having discoursed with great judgment and learning before Leontius, king of the Phliasii, that prince asked him, what art he professed; or in what points his wisdom chiefly lay? To which he answered, that he neither understood any art, nor was he σοφος, but φιλοσοφος. Which title, St. Augustine observes, took so well with other authors, that whoever excelled in any thing relating to wisdom or knowledge had afterwards no other appellation. Accordingly Socrates, Plato, &c. ever refrained from the swelling title of *sophos*.

By *philosophy* we mean the knowledge of the reasons of things, in opposition to history, which is the bare knowledge of facts; or to mathematics, which is the knowledge of the quantity of things or their measures.

These three kinds of knowledge ought to be joined as much as possible. History furnishes matter, principles, and practical examinations, and mathematics completes the evidence. *Philosophy* being the knowledge of the reasons of things, all arts must have their peculiar *philosophy* which constitutes their theory: not only law and physic,

but the loweſt and moſt abject arts are not deſtitute of their reaſons, which might uſefully employ the time of the ſtudious. It is true, thoſe who call themſelves *philoſophers* and learned men have as yet done little towards forwarding the intelligence of arts: but we ſpeak not of what is done, but of what ought to be done.

One great obſtacle to the progreſs of arts and ſciences has been the neglect of practice in ſpeculative men, and the ignorance or contempt of theory in mere practical men. What chimeras and abſurdities the neglect of experience and practice has produced, need not be mentioned; the miſchiefs ariſing from a neglect of theory are not ſo obvious: yet certainly it retards the progreſs of arts. All invention or improvement muſt be either caſual or rational, including analogy or inference from ſimilar caſes, under the term rational. Now, although the foundations of arts have often been owing to ſome caſual diſcovery, as gunpowder, or the loadſtone, yet is this not to be truſted to alone. Improvements in no always flow from this ſource, but rather *from* the reflexions of ſenſible; and, if theſe reflexions were rendered more diſtinct, more communicable, and eaſier to be retained, by the proper uſe of ſigns and other *philoſophical* helps, great advantages might be expected: it being certain, that *philoſophical* knowledge is more extenſive, and more ſure in the application; and, beſides, gives a pleaſure to the mind not to be expected from that which is merely hiſtorical.

It is to be obſerved, that the bare intelligence and memory of *philoſophical* propoſitions, without any ability to demonſtrate them, is not *philoſophy*, but hiſtory only. However, where ſuch propoſitions are determinate and true, they may be uſefully applied in practice, even by thoſe who are ignorant of their demonſtrations. Of this we ſee daily inſtances in the rules of arithmetic, practical geometry, and navigation; the reaſons of which are often not underſtood by thoſe who practiſe them with ſucceſs. And this ſucceſs in the application produces a conviction of mind, which is a kind of medium between *philoſophical*, or ſcientifical, and hiſtorical knowledge.

The ingenious author of the Analyſt has gone ſo far as to ſuggeſt, that mathematicians have no other conviction of the truth of the doctrine of fluxions.

We have ſaid that *philoſophy* is the knowledge of the reaſons of things. It may be aſked, what are the reaſons of things, or what is the explication of phenomena or facts? An ingenious author tells us, that the explication conſiſts only in ſhewing the conformity any particular phenomenon hath to the general laws of nature; or, which is the ſame thing, in diſcovering the uniformity there is in the production of natural effects. This he thinks evident to any one whoever ſhall attend to the ſeveral inſtances wherein philoſophers pretend to account for appearances. By a diligent obſervation of the phenomena within our view, we may diſcover the general laws of nature, and from thence deduce, though not demonſtrate, other phenomena; all deductions of this kind depending on a ſuppoſition that the Author of Nature always operates uniformly, and in a conſtant obſervation of thoſe rules we take for principles; which we cannot evidently know.

If we take a view of the ſeveral phenomena, and compare them together, we may obſerve ſome likeneſs and conformity between them. For example, in the falling of a ſtone to the ground, in the riſing of the ſea towards the moon, in coheſion and cryſtalliſation, there is ſomething alike, namely, an union or mutual approach of bodies: ſo that any one of theſe, or the like phenomena, may not ſeem ſtrange, or ſurpriſing, to a man who has nicely obſerved and compared the effects of nature; for that only is thought ſo which is uncommon, or a thing by itſelf, and out of the ordinary courſe of our obſervation. That bodies ſhould tend towards the centre of the earth, is not thought ſtrange, becauſe it is what we perceive every moment of our lives; but that they ſhould have a like gravitation towards the centre of the moon, may ſeem odd and unaccountable to moſt men, becauſe it is diſcerned only in the tides; but a philoſopher, whoſe thoughts take in a larger compaſs of nature, having obſerved a certain ſimilitude of appearances, as well in the heavens as the earth, that argue innumerable bodies to have mutual tendency towards each other, which he denotes by the general name attraction, whatever can be reduced to that, he thinks juſtly accounted for. Thus he explains the tides by the attraction of the terraqueous globe towards the moon, which, to him, doth not appear odd or anomalous, but only a particular example of a general rule or law of nature.

If, therefore, we conſider the difference there is between natural philoſophers, and other men, with regard to their knowledge of the phenomena, we ſhall find it conſiſts not in an exacter knowledge of the efficient cauſe that produces them, for that can be no other than the will of a ſpirit; but only in a greater largeneſs of comprehenſion, whereby analogies, harmonies, and agreements are deſcried in the works of nature, and the particular effects explained; that is, reduced to general rules, which rules grounded on the analogy and uniformneſs obſerved in the production of natural effects, are more agreeable, and ſought after by the mind; for that they extend our proſpect beyond what is preſent, and near to us, and enable us to make very probable conjectures, touching things that may have happened at very great diſtances of time and place, as well as to predict things to come; which ſort of endeavour towards omniſcience is much affected by the mind. Berkeley, Princ. of Hum. Knowledge, ſects. 103, 105.

PHILOSOPHY is a term uſed in various ſignifications among ancient and modern writers. In its laxeſt ſenſe, it ſignifies the love of truth: thus Plato frequently calls it *philalethia*.

In other places it ſignifies the knowledge of many things; thus Zeno calls *philoſophy*, πολυμαθίαν, *manyknowledge*, becauſe comprehending all truth. Agreeable to which is Cicero's definition of philoſophy, that he is one who ſtudies to know the natures and cauſes of all things human and divine, and to attend to every good rule and method of life.

PHILOSOPHY, in a narrower ſenſe, is frequently confined to ſome one ſcience, or branch of ſcience: v. gr. to logic, as we find it in Plato and Ariſtotle: to phyſics, or the knowledge of nature; in which ſenſe it was chiefly uſed in the Ionic ſchool: and to ethics, or the rules of morality: thus it is Clemens of Alexandria relates, that among the Greeks there are philoſophers who hold diſputes about virtue.

Agreeable to this laſt application, Pythagoras defines *philoſophy* a meditation or ſtudy by which, according to Plato and Clemens, is meant an abſtraction or retirement from the body; which Apuleius thus explains: a philoſopher is to ſtudy nothing ſo much as to let his ſoul at liberty from its correſpondence with the body: thus Cicero calls *philoſophy*, *ars vitæ*, and Seneca, *ſcientia* and thus Plutarch. Conſtancy, fidelity, and a found mind, are the real *philoſophy*; all the other parts of wiſdom, tending any other way, are pretenſions and curioſities: and in this ſenſe it was, that *philoſophy* chiefly flouriſhed in the ſchools of Socrates, afterwards called the *Academic ſchool*, and among the Stoics.

PHILOSOPHY, again, is frequently uſed by Pythagoras and Plato for metaphyſics, or the knowledge of God: which Plato calls the *true philoſophy*, others the *prima philoſophia*; and in reſpect whereof, the Platoniſts call all other *philoſophy*, κατθυρια, *outward diſcourſe*.

Gale includes the ſeveral notions hitherto delivered, under this one general definition: *philoſophy* is the knowledge of things natural, moral, ſupernatural, and notional; originally granted by God to our firſt parents, and tranſmitted to us for the honour of the Creator and the good of the univerſe.

That definition of Epictetus is alſo pretty comprehenſive: *philoſophy*, he ſays, conſiſts in three things; the practice of precepts, the reaſon of precepts, and the proof of precepts.

Some having given the following appellations to the ancient *philoſophy*, under its ſeveral ſtages: *philoſophy*, ſay they, became *impious* under Diagoras; *vicious* under Epicurus; *hypocritical* under Zeno; *impudent* under Diogenes; *covetous* under Demochares; *contentious* under Metrodorus; *fantaſtical* under Crates; *fearleſs* under Metippus; *licentious* under Pyrrho; and *quarrelſome* under Cleanthes.

The ſeveral dogmata, maintained by the ſeveral philoſophers, are infinite: Cicero makes no ſcruple to aver, that there is nothing in the world, how abſurd ſoever, but has been maintained by one *philoſopher* or other.

From the firſt broachers of new opinions, and the firſt founders of ſchools, *philoſophy* is become divided into innumerable ſects; ſome ancient, others modern: ſuch are the Platoniſts, Peripatetics, Epicureans, Stoics, Pyrrhonians, and Academics; and ſuch are the Carteſians, Newtonians, &c. See the riſe, doctrines, &c. of each ſect under PLATONISM, PERIPATETICS, EPICUREANS, STOICS, PYRRHONIANS, ACADEMICS, CARTESIAN, NEWTONIAN, &c.

Philoſophy may be divided into two branches, or it may be conſidered under two habitudes, *theoretical* and *practical*.

PHILOSOPHY, *theoretical*, or *ſpeculative*, is that employed in mere contemplation, and which terminates therein. Such is phyſics, which is a bare contemplation of nature, and natural things.

Theoretical philoſophy, again, is uſually ſubdivided into three kinds; viz. pneumatics; phyſics, or fomatics; and metaphyſics, or ontologia.

The firſt conſiders being, abſtracted from all matter; its

objects are *spirits*, their natures, properties, and effects. The second considers matter, and material things: its objects are bodies, their properties, laws, &c.

The third extends to each indifferently: its objects are either body or spirit.

In the order of our discovery, or arrival at the knowledge of them, physics is first, then metaphysics; the last arises from the two first considered together: after an acquaintance with God, ourselves, and natural bodies, we come to consider what is common to them all, or the attributes that agree to all: and thus form a sort of universal *philosophy*, or doctrine *de ente* in general.

But in teaching, or laying down, these several branches to others, we observe a contrary order; beginning with the most universal, and descending to the more particular. And hence we see why the Peripatetics call metaphysics, and the Cartesians pneumatics, the *prima philosophia*. Others prefer the distribution of *philosophy* into four parts, viz. 1. Pneumatics, which considers and treats of spirits. 2. Somatics, of bodies. The third compounded of both, anthropology, which considers man, in whom both body and spirit are found. 4. Ontosophy, which treats of what is common to all the other three.

Philosophy may be divided into three parts; intellectual, moral, and physical; the intellectual part comprises logic and metaphysics; the moral part contains the laws of nature and nations, ethics and politics; and, lastly, the physical part comprehends the doctrine of bodies, animate or inanimate: these, with their various subdivisions, will take in the whole of *philosophy*.

Wolfius makes the three parts of *philosophy* to be the doctrine of God, the human soul, and of bodies. However when he subdivides, and comes to treat the several branches separately, his divisions readily come under the three heads, intellectual, moral, and physical, before mentioned. The doctrine of God, and the human soul, may be ranged under the same head, metaphysics, the notion of the divine nature being formed from that of the human soul, excluding limitations and imperfections. Muschenbroek divides *philosophy* into six parts, viz. Pneumatics, or the doctrine of spirits; physics, whose object is the universe and the bodies contained therein; teleology, which explores the design and end of the existence of all bodies, and of all their actions and changes, as far as human sagacity can discover them; metaphysics, which comprehends the general and abstract natures and qualities of objects, containing ontology and cosmology; practical or moral *philosophy*, which lays down rules for the right conduct of life, and the attainment of true happiness; and logic, which unfolds the powers and directs the exercise of the intelligent and reasoning faculty of the human mind.

PHILOSOPHY, *practical*, is that which lays down the rules of a virtuous and happy life; and excites us to the practice thereof.

Practical philosophy is properly ethics alone, or the method of leading a virtuous and happy life. Yet most authors divide it into two kinds, answerable to the two sorts of human actions to be directed thereby; viz. 1. LOGIC, which governs the operations of the understanding.

2. ETHICS, properly so called, which direct those of the will.

PHILOSOPHY, *natural*. See NATURAL.

PHILOSOPHY, *moral*. See MORAL.

PHILOSOPHY is also frequently used for the particular doctrine or system of opinions, broached by some considerable philosopher, and espoused, and adhered to by his followers.

In this sense we say,

PHILOSOPHY, *Arabian*, *Aristotelian*, *Cartesian*, *Epicurean*, *Hermetical*, *Lutherian*, *Newtonian*, *Oriental*, *Platonic*, and *Stoical*. See PERIPATETIC, &c.

PHILOSOPHY is also used for a certain manner of philosophizing; or certain principles, upon which all the enquiries thereby made do turn.

In this sense we say,

PHILOSOPHY, *corpuscular* or *atomical*, *mechanical*, and *experimental*. See the adjectives.

PHILOSOPHY, *again*, is considered with regard to the age, or the place, wherein it was taught.

In this sense we say,

PHILOSOPHY, *new*, &c. See MECHANICAL *Philosophy*.

PHILOSOPHY, *scholastic*, or *school*. See SCHOLASTIC.

PHILTER, PHILTRE, PHILTRUM, in *Pharmacy*, &c. a strainer, or FILTER.

PHILTRE, φιλτρον, formed of φιλεω, *I love*, is also used for a drug, or preparation, or charm, which it is pretended will excite love.

Philters are distinguished into true and spurious: the spurious are spells or charms, supposed to have an effect beyond the ordinary laws of nature, by some magic virtue; such are those said to be given by old women, witches, &c.

The true *philters* are supposed to work their effect by some natural and magnetical power. There are many enthusiastic authors who believe the reality of these *philters*; and alledge matter of fact in confirmation of their opinion: among the rest is Van Helmont, who says, that, upon holding a certain herb in his hand for some time, and taking afterwards a little dog by the foot with the same hand, the dog followed him wherever he went, and quite deserted his former master.

He accounts for the phenomena of love transplanted by the touch of an herb: by asserting, that the heat communicated to the herb, not coming alone, but animated by the emanations of the natural spirits, determines the herb towards the man, and identifies it to him: having then received this ferment, it attracts the spirit of the other object magnetically, and gives it an amorous motion. But all this is mere cant; and all *philters*, whatever facts may be alledged in their favour, are mere chimeras.

Naturalists ascribe an effect, somewhat of kin to that of a *philter*, to cantharides taken inwardly: these, it is true, tend to excite love, or rather lust; but it is lust in the general, not determined to any particular object; and they do it no otherwise than by irritating the fibres of the nerves and muscles, by whose action the emissio seminis is effected. See FILTER.

PHILTRATION, or FILTRATION. See FILTRATION.

PHILYRA, in *Natural History*, a name given to the substance on which some of the most ancient books are written. It is the inner bark of the *tilia*, or common lime-tree. The emperor's library at Vienna has a book, written by Tully, never yet published, which is written on this substance.

PHIMOSIS, φιμωσις, properly signifying a ligature with packthread, (φιμος denoting packthread,) in *Medicine*, a disease of the penis, wherein the præputium is by a violent inflammation glued, or strongly constringed, upon the glans; so as not to be capable of being drawn back, to uncover the glans.

Sometimes a *phimosis* conceals chancres on or about the glans; and sometimes it is so violent, as to prevent the flowing out of the matter; whence it causes an inflammation or mortification of the part. When the prepuce is detained behind the glans, the case is called a PARAPHIMOSIS.

This disorder is usually communicated by commerce with unclean women, whereby the virulent matter lodged in the sinuses of the vagina insinuates itself betwixt the glans and præputium, where remaining, it occasions an inflammation, with the *phimosis*: however instances have occurred of a natural strictare in the præputium, so that the glans cannot at all or with great difficulty be denudated. When the *phimosis* does not proceed from infection, it will be sufficient to bathe the parts in warm water: but if it be a venereal case, proper internal medicines are to be exhibited at the same time, whilst the pain and other symptoms are mitigated, by washing out the virulent matter with warm water, and frequently repeating an injection of decoction of barley and honey. To disperse the tumor, a discutient fomentation or cataplasm may be afterwards applied to the penis.

The cure of a paraphimosis in no-wise differs from that of a *phimosis*, except in the use of injections; and in both cases, if they still prove obstinate, the prepuce must be cut, in order to reduce it to its natural state or situation. See GONORRHŒA.

PHIMOSIS is also used for a disease of the eyes, wherein the eye-lids are so bound together by the mediation of some glutinous matter, that they are not to be opened.

PHLEBOTOMY, φλεβοτομια, compounded of φλεψ, vein, and τομη, *to cut*, in *Medicine* and *Surgery*, *bleeding*; or the art or operation of letting blood. See BLEEDING.

PHLEGM, φλεγμα, in *Chemistry*, an aqueous and insipid fluid, supposed to be found in all natural bodies; coinciding with what the other philosophers call *water*.

Phlegm makes the fourth of the chemical elements, or elementary principles.

In the distillation of vinegar, as also of all minerals and inodorous vegetables, *phlegm* comes out first; in that of wine, last.

This *phlegm* is supposed to be the common vehicle and diluter of all solid bodies; and in proportion to its quantity in their mixture are the other parts more languid and disabled in their attraction: yet on the chemists system, *phlegm* should be a principle of action, as being necessary to the dissolution of the salt in bodies, and without which the salt must remain inactive.

It is much to be questioned, whether this *phlegm* can ever be procured without some mixture of other matters; that, which has the least of them, must come nearest to the nature of a principle; and, on that account, rain-water should afford it most.

Phlegm, Boerhaave observes, drawn by distillation from vegetables, always carries with it somewhat of the smell

of the vegetable, which it derives partly from the oil, and partly from the ſpirit reſiding therein. The ſame *phlegm*, by frequently reiterated diſtillations, lays aſide moſt of its ſmell, and approaches nearer to pure water; but it never becomes perfectly ſuch. Add, that the pureſt diſtilled water, if expoſed a few days to the ſun, is much changed and rendered turbid.

That *phlegm* is not an elementary body, Mr. Boyle argues from its different powers and properties: the *phlegm* of wine, and that of moſt liquors, have qualities that make them differ from mere water, and alſo from each other: the *phlegm* of vitriol, that author obſerves, is an effectual remedy againſt burns, and a valuable noſtrum for diſſolving hard tumors; and that of vinegar will extract a ſaccharine ſweetneſs out of lead, and even diſſolve corals with long digeſtion; and that of ſugar of lead is ſaid to diſſolve even pearls.

In effect, the characters which ſerve to denominate a fluid, *phlegm*, or water, among the chemiſts, are inſipidity, and volatility; yet quickſilver has both theſe, which nobody pretends to be *phlegm*. Add, that it appears, from ſeveral experiments, that water itſelf, by repeated diſtillations, may be converted into earth: yet water, the ſame author obſerves, has a much fairer preſence to be an element, than any other of the *tria prima*.

Add, that, as to the qualities which occaſion that name to be given any viſible ſubſtance; viz. its being fluid, inſipid, and inodorous, we have never yet ſeen any of theſe ſeparated ſubſtances, which the chemiſts call *phlegm*, which were perfectly deſtitute both of taſte and ſmell.

Common ſalt, and ſeveral other ſaline bodies, diſtilled ever ſo dry, will each yield a large quantity of *phlegm*; which can no other way be accounted for but from this, that among the various operations of the fire on the matter of a concrete, ſeveral particles of that matter are reduced to a ſhape and ſize, requiſite to compoſe ſuch a liquor as the chemiſts call *phlegm*, or water.

PHLEGM, in the *Animal Oeconomy*, is one of the four humours, whereof the ancients ſuppoſed the maſs of blood to conſiſt.

Phlegm is the ſame that is otherwiſe called PITUITA.

PHLEGMAGOGUE, φλεγμαγωγὸς, formed from φλέγμα, *pituita*, and ἄγω, *to drive* or *draw*, a medicine proper to purge *phlegm*, or *pituita*.

Agaric, hermodactyls, turbith, and jalap, are reputed *phlegmagogues*.

PHLEGMASIA, a word uſed by ſome of the medical writers for an inflammation. Hippocrates alſo ſometimes uſes it to expreſs the violent heat in fevers.

PHLEGMATIC, φλεγματικὸς, a temperament, wherein *phlegm*, or *pituita*, is the prevailing humour.

Phlegmatic conſtitutions are ſubject to rheums, defluxions, &c.

PHLEGMON, φλεγμονὴ, formed from φλέγω, *to burn*, or *inflame*, in *Surgery*, a general name for all hot or inflamed tumors, formed in the fleſhy or bloody parts of the body.

An INFLAMMATION, attended with a conſiderable ſwelling of the parts, conſtitutes a *phlegmon*.

If the blood be good and laudable, and only peccant in quality, it is called a *true phlegmon*.

When corrupted and adulterated with bile, or pituita, it is called a *baſtard phlegmon*; in which caſe, it particepates of the eryſipelas, œdema, or ſcirrhus.

The blood, here extravaſated, produces a heat, redneſs, tenſion, remitency, pulſation, and great pain. The bubo, carbuncle, furuncle, puſtules, and other tubercles ariſing from the blood, are all reducible to the *phlegmon*, &c. The ophthalmia, parotides, ſquinancy, and even pleuriſy and peripneumony, are ſpecies of the *phlegmon*.

If the proximate cauſe of theſe tumors be enquired into, we ſhall find it generally riſes from too thick or viſcid a ſtate of the blood, ſtagnating in the anaſtomoſes of the ſmalleſt veins and arteries; ſo that the blood being propelled in larger quantities than can paſs through thoſe veſſels, it muſt of conſequence excite the ſymptoms that are the attendants of this tumor, and occaſion great diſorder at every part where ſuch ſtagnation is made.

No part of the body, whether external or internal, is perfectly exempt from this ſort of tumor, not even the bones themſelves; but it is more common in the fat and glands than elſewhere.

The cauſes of this ſtagnation of the blood are either external or internal.

Among the external, are all wounds, fractures, luxations, contuſions, punctures, by thorns and ſplinters, with a too great compreſſion of the veſſels, whether by too ſtrict a bandage, or by other means; each of which obſtructing the paſſage of the blood through its minute veſſels, either by dividing, bruiſing, compreſſing, or diſtorting them, may give riſe to this tumor.

And to theſe may be added burns of all kinds, with too violent cold, the too great motion of the body, the external application of ſharp and ſtimulating ſubſtances to the ſkin, and others, which ſtop the pores of the ſkin, and impede the circulation of the blood.

Among the internal cauſes, are to be reckoned the too great acrimony of the blood, as in ſcorbutic habits, the blood's abounding in too great quantities, or being of too thick a conſiſtence, or, laſtly, its circulating in the body with too violent a motion; for by this laſt means, the groſſer particles of the blood are protruded, and wedged in, as it were, in the ſmaller veſſels, through which they cannot find a paſſage; and this is eſpecially the caſe, when a ſudden cold is given to the body from a ſtate of extreme heat. In ſhort, every thing will produce an obſtruction that makes either the particles of the blood too large, or the mouths of the veſſels too ſmall and narrow to receive them.

The reſolution or diſperſion of a tumor of this kind is only practicable when the tumor is of a milder kind; when it is in a ſound habit of body, and when the blood is not yet too viſcid, or too violent in its motion: but ſuppuration follows when the inflammation is more violent, the circulation more rapid; but yet the maſs of blood ſomewhat temperate and free from acrimony.

That is, when the blood becoming more inſpiſſated, and its larger particles ſticking in the more minute veſſels, can find no paſſage; but the ſmall veſſels are burſt by the preſſure and impulſe of the obſtructed blood, ſo that their contents are extravaſated in the fat, fleſh, and adjacent parts. Upon this extravaſation, the more ſubtle and fluid parts of the blood putrefy, by means of the great heat, and become fœtid and acrimonious, and corrode the adjacent parts: the fluids thus changed or corrupted, are, by the ſurgeons, called matter or pus; and this of ſeveral kinds, according to its conſiſtence and colour: it is either white, yellow, greeniſh, reddiſh, or party-coloured.

When the forementioned ſymptoms are much more violent, and the blood at the ſame time more acrimonious than it ought to be, this inflammation generally terminates in a gangrene: for, in that caſe, the ſmalleſt arteries and veins are corrupted, burſt, and broke; and hence the adjacent parts are diſſolved and corrupted by theſe extravaſated acrimonious humours, and particularly the ſkin is very ſubject to be filled with puſtules, when its cuticle has been ſeparated, as in burns.

The ſanies contained in theſe puſtules and elſewhere is uſually termed ichor, and is generally of a pale reddiſh caſt, and ſometimes brown or livid, which is much worſe; for unleſs the patient in this caſe is timely aſſiſted, the ſymptoms of inflammation all go off, the tumor, reſiſtance, heat, redneſs, pain, and pulſation, gradually diſappear, and the limb becomes flaccid and cold; it afterwards turns pale, and becomes dead and inſenſible, and the inflammation creeps to ſome other part.

If this caſe be treated with medicines too hot, too aſtringent, cooling, fat, acrimonious, or narcotic; or if the parts be bound too tight, the fleſh quite dies, its paleneſs turns to a livid lead colour; and the incloſed ſanies, finding no vent, becomes more acrimonious, and ſo greatly corrodes the adjacent parts, as to deſtroy all ſenſe and motion, and brings on an entire ſphacelation of the whole limb. But if the inflamed part be full of glands, and the blood very thick, glutinous, and tough, the ſmall veſſels are then ſtrongly ſtuffed up with it, and impacted together; and the parts loſing their ſenſation, become changed into a hard tumor, called a ſcirrhus. The cure of *phlegmons* is by diſperſing or ſuppuration: the methods for bringing on theſe, ſee under INFLAMMATION and SUPPURATION. Heiſter.

PHILEOS, in *Botany*. See PHLEOS.

PHLEUM, in the Linnean ſyſtem of *Botany*, a graſs called *cypreidia*, or *cat's-tail graſs* by Scheuchzer, which makes, with this author, a diſtinct genus of plants, of the *triandria digynia* claſs: the characters of which are, that the cup is a glume, containing one flower; it is bi-valve, oblong, ridged, and compreſſed, and opens into a double-pointed ſummit; the valves are erect, hollowed, compreſſed, equal in ſize, and bearded; the flower is compoſed of two valves, ſhorter than thoſe of the cup, the outer one, which is the larger, ſurrounding the inner or ſmaller one; the ſtamina are three capillary filaments, longer than the cup; the antherœ are oblong, and divided into two at the ends; the germen of the piſtil is roundiſh; the ſtyles are two in number, ſmall and bent; and the ſtigmata are plumoſe: the cup and flower incloſe the ſeed, which is ſingle, and of a roundiſh form. There are five ſpecies.

PHLOGIDIAUGIA, formed from φλογίζω, *I inflame*, and αὐγὴ, *tranſparence*, in *Natural Hiſtory*, the name of a claſs of inflammable foſſils, of a pure texture, and in ſome degree tranſparent.

Of

Of this class are the sulphurs, orpiments, realgars, and amber.

They are by this name distinguished from the PHLOGISCHERIA. Hill.

PHLOGINOS, the name of a stone found in Ægypt, and called by some *chrysites*, from its colour resembling gold.

PHLOGISCHERIA, derived from φλογιζω, and χειρ, *a hand*, in *Natural History*, the name of a class of fossils, the characters of which are, that the bodies contained in it are inflammable, of a coarse and impure texture, and not pellucid.

The bodies of this class are divided into two general orders, and under those, into five genera. Those of the first order are such as are found loose, and in detached masses: those of the second, such as are found constituting whole strata. The genera of the first order, are ambergrise, jet, and the asphaltæ; and those of the second, canal and common coal.

PHLOGISTON, formed of φλογιζω, *I am inflamed*, in *Chemistry*, is defined to be the most pure and simple inflammable principle. That such a principle exists, in various degrees and modes of combination, in different bodies is a fact, which has been long and generally acknowledged. Some bodies have been observed to be capable, by exposure to fire with the concurrence of air, of being kindled, of producing flame, of augmenting the fire, and of maintaining and supporting it; while other bodies, by exposure to fire, did indeed, become hot, red, and luminous, but were incapable of producing flame and of maintaining fire. Hence chemists have been always led to distinguish these two kinds of bodies, calling the former combustible, and the latter incombustible; and they supposed, that the inflammability of combustible bodies was the effect of a principle, which did not exist in those that were incombustible. However some late writers have controverted this hypothesis, and the distinction founded upon it. Dr. Priestley conjectures, that the difference between the substances which are called inflammable, and others which also contain *phlogiston* may be this, that in the former the heat, or the vibration occasioned by the emission of their own *phlogiston*, may be sufficient to occasion the emission of more till the whole be exhausted; that is, till the body be reduced to ashes. Whereas in bodies which are not inflammable, the heat occasioned by the emission of their own *phlogiston* may not be sufficient for this purpose, but an additional heat *ab extra* may be necessary.

M. Beneber, another ingenious author who has treated of this subject, does not seem willing to allow, that there is any body to be found which is incombustible, or proof against fire; and he observes, that even if such a body were found, it would not be reasonable to conclude, that it had no *phlogiston*, but only that *phlogiston* adheres most tenaciously to those bodies which resist the impression of fire; and he adds, that there is no body which remains incombustible, if *phlogiston* be added to it, to facilitate the dispersion of that which it already contains. This inflammable principle cannot be separated from the other principles of bodies and obtained pure; and, consequently, as it is impossible to discover all the properties which are peculiar to it, and which distinguish it from all other substances, its precise nature has been very imperfectly understood. Hence the ancient chemists confounded it with oil and sulphur, which are only substances into the composition of which a great quantity of this principle enters: nor did they seem to know, that only one inflammable principle exists, always the same, always similar to itself, in oils, sulphur, coals, and all other bodies, which the modern chemists since the time of Stahl have sufficiently ascertained: so that it is now generally allowed, that *phlogiston* is the same in the three great classes of natural bodies, i. e. in the animal, vegetable, and mineral kingdoms. That which is extracted from minerals is precisely the same with that of the charcoal of animal and vegetable substances; *phlogiston* may also be transmitted from bodies of one class to those of another, and it produces, in this case, the same effects as if it had been taken immediately from the bodies of the class to which it is transmitted. After all the combinations, through which it may have passed, it remains invariably the same, and always comes forth with its primitive characters. Beecher calls this principle inflammable earth, and Stahl called it the principle of inflammability or *phlogiston*.

Some philosophers dislike the term *phlogiston*, and call the inflammable principle the elementary fire of bodies: but there seems to be no just objection against giving that or any other name to a real something, the presence or absence of which makes so remarkable a difference in bodies as that of metallic calces and metals, oil of vitriol and bituminous, &c. and which may be transferred from one substance to another, according to certain known laws: or, as one and the same unknown cause of certain well known effects. Whereas the term fire, used to denote a constituent principle of natural bodies, is more ambiguous, because in common acceptation it includes *heat*, which has no more proper connection with *phlogiston* than it has with water or any other constituent part of bodies; and it will be necessary to recur perpetually to the distinction of fire in a state of action and fire inactive or quiescent.

It has been controverted among writers on this subject, whether *phlogiston* be pure elementary fire in its state of combination with the bodies in which it is found, if in this state it be susceptible of combining without any intermediate substance; or whether, in order to this combination, it be necessary that this element should be previously combined with some other substance, and consequently, that it is only a secondary principle. In favour of the former opinion it is urged, that the inflammable principle of bodies cannot be separated and procured from bodies in any other state than that of free and active fire, and that it is deprived of its activity by the union which it contracts with other substances. If this be the case, *phlogiston* has no other property than those which arise from the union of pure fire with the several substances to which it is united. But it is alledged on the contrary, that when *phlogiston* is taken from one body by means of another applied to it, it unites with this as soon as it is disengaged from the former; and, therefore, the advocates of this opinion maintain, that it is not procured pure and alone, because it only quits one combination to enter at the same time into another.

Beneber maintains, that the *phlogiston*, which falls under our observation, seems to be always united to an acid; and that which appears to be the most generally combined with it is the vitriolic acid, which, at least, abounds in all combustible bodies. But he conjectures, that it is not always the same vitriolic acid, that is united to *phlogiston*; and that the difference in the effect produced by *phlogiston* in the bodies, where it is found, proceeds from the different acids with which it is combined in them. Thus, when it is united with the vitriolic acid, it forms sulphur; when it is combined with sea-salt, it produces, as he says, phosphorus; and joined with nitre, it loses its qualities and concentrates itself in bodies by means of that union. Although *phlogiston*, says this writer, exhibits itself almost always under an oily form, and more especially in charcoal, which is its proper mine or matrix, nevertheless it is not oil, but is possessed of qualities that are peculiar to it. The flame of charcoal has not the acidity of the flame produced by oil; the former is rather of a bluish cast; the latter of a whitish colour. The flame of charcoal leaves behind it neither smoke nor soot; the flame of oil produces both, in quantities that depend upon the nature of the oil; the ether itself is more or less impregnated with a fuliginous vapour; burning charcoal exhales a portion of subtile matter, which does not appear under a burning form, such as the gas; and the result of this observation seems to be, that *phlogiston* is not enveloped with a substance of sufficient density to let the fuliginous particles escape like oils which waste away. The malignant vapour, which is formed by burning charcoal, bears several characters of *phlogiston*; like this latter, it is not coagulable; it has the same affinity with acids; it produces the same effects that result from the vapours of bodies in putrefaction, with this exception, that the vapour of charcoal appears more disengaged than that which arises from putrified bodies; but nothing seems to ascertain more fully the resemblance of these three vapours, than their affinity with the acid; and accordingly we find that the only method of removing their pernicious effects, is to make an acid evaporate in all places, where these effects are apprehended: in the use of this method, the acid, probably, envelopes the *phlogiston*, and diminishes its activity and volatility. Thus also acids diminish the effects of intoxication from drinking, because they act upon the *phlogiston* of wine, which attacks the nerves, in the same manner as they act upon that of charcoal, when it is diffused through a chamber. Although *phlogiston* is essentially volatile, it is nevertheless fixed, when it is not exposed in the air to the action of fire. Beneber is inclined to consider flame as the conductor of *phlogiston*; and this notion seems to be confirmed by an experiment of M. de Buffon.

However the question concerning the nature of *phlogiston* be determined, the power which chemists have of transferring the inflammable principle from one combination to another, by combustion and dissipation, has furnished them with the means of making many important observations on the effects which it produces in chemical operations, and of discovering the properties which it communicates to the several substances with which it unites. Some of these we shall collect together, and recite in the sequel of this article.

The union of *phlogiston* with an uninflammable substance

produces a new compound, which becomes inflammable and capable of producing heat and light more or less eaſily, according to the quantity of *phlogiſton* united with it, and the manner of its combination. This principle, united with bodies naturally ſolid, diminiſhes their hardneſs and renders them more fuſible; and it likewiſe diminiſhes the fixedneſs of the body in which it is combined. It increaſes the abſolute gravity, and frequently the ſpecific gravity of bodies into which it enters; and in ſome caſes renders them opake. Subſtances, which have neither ſmell nor colour, acquire generally one or the other, and frequently both, by their union with the inflammable principle; and hence chemiſts have been inclined to conſider it as the principle of colours and ſmells; although ſome bodies which contain *phlogiſton* in a ſmall quantity have neither any ſenſible colour nor ſmell. It is obſerved that *phlogiſton* is not equally diſpoſed to unite with all ſubſtances; that it combines very difficultly with fluid, volatile and light matters, ſuch as air and water; but it may be eaſily combined with ſolid, fixed, and heavy ſubſtances, as earths. And it ſerves as a kind of intermedium ſubſtance for uniting together bodies that are either incapable of uniting, or that unite with difficulty without it. The combination of *phlogiſton* with different kinds of air and alſo with water, has been illuſtrated and evinced by a variety of experiments by Dr. Prieſtley: all the kinds of air, he ſays, that appear to be eſſentially diſtinct from each other are fixed air, acid, and alkaline; becauſe theſe and another principle, called *phlogiſton*, which he has not been able to exhibit in the form of air, and which has never yet been exhibited by itſelf in any form, ſeem to conſtitute all the kinds of air with which he is acquainted. See on this ſubject a Treatiſe on the various kinds of Gaſes, by the ingenious author of the Chemical Dictionary, in the Appendix, chap. 17.

Dr. Prieſtley has alſo ſhewn how common air is depraved and rendered unfit for the purpoſes of reſpiration, combuſtion, &c. by uniting with the *phlogiſton* diſcharged from the lungs of animals, from burning bodies, from calcined metals, from putrifying ſubſtances, &c. and in ſome caſes being ſaturated with it, ſo as hereby to become phlogiſticated. And as a variety of cauſes contributes to the releaſe and diſcharge of *phlogiſton* from bodies in which it is combined, and from which by certain proceſſes it is diſengaged, which by uniting with the air diminiſhes it, precipitates its fixed air, and renders it noxious, he has diſcovered that vegetating plants purify the air by imbibing its *phlogiſton*, and that the agitation of water is alſo conducive to the ſame beneficial purpoſe.

A general abſtract of his diſcoveries may be found under the articles AIR and BLOOD. See alſo FIRE and HEAT.

It is obſerved, that there is no claſs nor kind of ſalts, that do not contain *phlogiſton* and that have not affinities with it. It has the greateſt affinity with acids, inſomuch that ſome writers have contended, that there is no *phlogiſton* without an acid. Of all the acids, the nitrous is that which has the greateſt affinity with the inflammable principle: its volatility, colour, and ſmell, its inferiority of ſtrength compared with vitriolic acid, its inflammability and total decompoſition by inflammation prove, that *phlogiſton* is one of the conſtituent parts of that acid; and beſides, it is known to act more ſtrongly in general than vitriolic acid upon all bodies that contain the inflammable principle, and more effectually deprives them of this principle, as is the caſe in the ſolutions of metals. In a dry ſtate it unites with *phlogiſton* in the moſt intimate manner, and forms a kind of ſulphur that may be called nitrous ſulphur, which is ſo inflammable, that it kindles as ſoon as it is formed, and can never, therefore, be obtained alone and uninflamed.

The marine acid is that which it is moſt difficult to combine with *phlogiſton*; for though it is lighter and more volatile than the vitriolic acid, it is incapable of acting upon many inflammable matters, as oils, or at leaſt, acts upon them in a very feeble manner, and takes little of the *phlogiſton* from metals. Beſides Macquer ſays, that there is no immediate combination of marine acid with *phlogiſton*, or marine ſulphur; the PHOSPHORUS of Kunckel not being, he ſays, of this kind, as Stahl and other chemiſts have apprehended. The union of *phlogiſton* with the vitriolic acid in a dry ſtate is known to produce ſulphur, the inflammability of which is cauſed by the *phlogiſton* contained in it, and which is decompoſed by the burning of its *phlogiſton*. Some have even ſuppoſed, that the different combination of *phlogiſton* with different acids may be one of the cauſes of the different affinities of bodies to each other.

Phlogiſton alſo unites itſelf with alkalis; and this union is manifeſt in putrid exhalations. Moreover, volatile alkalis produce the ſame effects that ariſe from the *phlogiſton*; they render the blood more fluid, increaſe its circulation, and excite perſpiration; and the odours of both are equally ſuffocating to thoſe who breathe the air that is impregnated with them. The fixed alkalis ſaturate themſelves with *phlogiſton*, when they are calcined in cloſe veſſels with charcoal or ſimilar ſubſtances. Nevertheleſs theſe alkalis ſeem to have leſs affinity with *phlogiſton* than the vitriolic and nitrous acids, or even than the metallic earths. *Phlogiſton* alſo unites itſelf with earthy ſubſtances under a dry form, and which are much attenuated, ſuch as clays, to which it adheres with great force: and it ſeems to be moſt diſpoſed to unite with theſe earths when it is in the ſtate of oil, of ſoot, or of vapour. The coals of vegetable and animal matters are nothing elſe than ſingular combinations of the earthy part of theſe organiſed bodies with the inflammable principle of their oils or fat: and yet this principle does not ſo much adhere to the earth of coals as not to quit it, in order to combine with other ſubſtances with which it has a ſtronger affinity, as with the vitriolic, nitrous, and phoſphoric acids, and with metallic earths.

Moreover, *phlogiſton* appears to be intimately combined with metals; without it they loſe their metallic properties, and with it they recover them. This is a truth which has been long known and demonſtrated. The difference of weight between a metal and its calx has been a phenomenon, which has much puzzled the chemiſts and philoſophers. Some, in order to account for this difference, have aſcribed abſolute levity to *phlogiſton*, which, by being combined with the calx under the form of metal, diminiſhes its weight. The true cauſe of this difference was firſt ſuggeſted by Jean Rey, in the beginning of the laſt century (ſee *Eſſential* HEAT), but for many years it was little known or regarded: however, it has been ſufficiently aſcertained by the late experiments of Hales, Prieſtley, Lavoiſier, &c. on *fixed* AIR. See CALCINATION.

The diſtinguiſhing characters of *phlogiſton* are moſt clearly diſcerned by comparing the properties of metals with thoſe of their calces. The latter are generally harder, more ſolid, more fixed, leſs denſe, leſs fuſible, and leſs opake than the former. Thus lead and tin are very ſoft metals; nevertheleſs, when lead is calcined and afterwards melted, a glaſs is formed much harder than the lead from which it was produced. Tin, which calcines ſtill more completely than lead, is eaſily changeable into white earth, the parts of which, though very fine, are ſo hard, that they are employed to poliſh very hard bodies, as ſteel, glaſs, &c. See PUTTY.

The moſt volatile ſemi-metals, as regulus of antimony and zinc, are changed by burning their *phlogiſton* into perfectly fixed earths. Regulus of antimony and tin are fuſible with a gentle heat; yet the calces of theſe metals are juſtly conſidered among the moſt refractory bodies. The denſity, opacity, and ductility which metals receive from their *phlogiſton*, evidently proceed from the particular manner in which the parts of the *phlogiſton* are applied to thoſe of the metallic earths.

Many facts have been lately urged to evince the identity of *phlogiſton* and the electric matter: they reſemble one another in the light and ſmell they afford, and in the effects they produce on animals and vegetables; they both accelerate the circulation of the blood, and of the ſap; they augment the fluidity of both; they alike occaſion cutaneous eruptions, remove obſtructions in the veſſels, irritate the muſcles, and act upon them when all other ſtimulants are ineffectual. They concur in deveſoping the parts of animals and vegetables in promoting their growth: animals, that are killed by lightning or by the electrical ſpark, ſeem to be affected in the ſame manner with thoſe that are ſuffocated by mephitic or phlogiſtic vapours. The ſame cauſes, which diſſipate the electric fluid, ſeem alſo to diſſipate the *phlogiſton*, and to occaſion a ſtate of bodily inquietude in perſons who are valetudinary, by depriving them of too large a quantity of *phlogiſton*: thus, a moiſt and humid air affects both the one and the other in the ſame manner. The moments preceding thunder-ſtorms are burthenſome and oppreſſive, becauſe they accumulate on the nerves too great a quantity of *phlogiſton*, or electrical fluid. Thus, like *phlogiſton*, melts and calcines metals, and revivifies their calces.

Phlogiſton and the electrical fluid are known to promote evaporation; the electrical ſpark infects the air, juſt as *phlogiſton* does where it abounds; they both depoſit fixed air, diminiſh common air, and form a precipitate in lime-water.

From theſe and other ſimilar effects, it is concluded, and not without reaſon, that the electric matter either is or contains *phlogiſton*. See *Theory of* ELECTRICITY.

Light is alſo ſuppoſed to be a modification of *phlogiſton*; and this ſuppoſition is rendered probable, not only by many electrical phenomena, if the identity of the electric matter and *phlogiſton* be admitted, but by the known fact, that no other ſubſtances beſides thoſe which contain

phlogiston are capable of ignition, and of becoming luminous. For an account of several curious observations and experiments relating to *phlogiston*, in its connection with heat. See HEAT.

Modern chemists and philosophers have ascribed a very extensive operation and use to *phlogiston*, in the whole oeconomy of nature. See AIR, BLOOD, COMBUSTION, CONDUCTORS, METALS, MUSCULAR *Motion*, NUTRITION, PLANTS, PUTREFACTION, VEGETATION, &c.

A late author, however, in a Discourse on *Phlogiston*, has attacked the generally received doctrine concerning *phlogiston*; and he concludes with saying, that nothing true and certain is known concerning the nature of this principle. See on the subject of this article, Chemical Dict. Eng. edit. art *Phlogiston*. Scheibler's Mem. sur le Phlogistique, &c. published in the abbe Rozier's Journal; and Priestley's Observations, &c. on Air, in 2 vols 8vo. passim.

The ingenious and indefatigable Dr. Priestley informs the editor, that from some late experiments, not yet published, he has reason to conclude, that *phlogiston* is simply *inflammable air*, in a state of combination with any substance, just as fixed air is contained in chalk, &c. With a view of ascertaining the nature and reality of *phlogiston*, he threw the focus of a burning lens on some calx of lead, out of which all air had been expelled, when it was confined in inflammable air. The consequence was, that the air was rapidly absorbed, lead was formed, and what remained of the air was just as inflammable as at first. From about forty ounce measures of the air, obtained from iron by oil of vitriol, he got about five penny-weights of lead.

PHLOGITES, in *Natural History*, a name given by Pliny and other authors to a stone, which they say had the appearance of flames of fire, bubbling up and rising to several points within it. It is sometimes called also *phlegonites*.

Some have supposed that the ancients meant no more by this distinction, than to express a fire colour lodged in the stone.

Pliny ranks the *phlogites* among the gems, but Sabinus and others place it among the larger stones: and we have from some parts of Germany, a spar, with radiations of a fiery red in a white ground, which looks as like flames as any thing one could expect in a stone; but whether this, or some other, be the stone called petrified flames of fire by the collectors of that nation, we are not assured.

PHLOGONLÆ, in *Natural History*, the name of a class of fossils, usually included by authors with many others of a very different kind, under the general name pyrites. These are defined to be compound, inflammable, metallic bodies, found in small masses, and of determinately angular figures. Of this class of bodies there are three genera, viz. the *pyricubia*; the *pyrodactonia*; and the *pyripolygonia*. See PYRICUBIA, &c.

PHLOGOSIS, Φλογωσις, in *Surgery*, sometimes denotes a slight degree of the OPHTHALMIA: in general it denotes a disposition to inflammation.

When the inflammation of the eye is light and gentle, it is called a *phlogosis*, when very severe, a CHEMOSIS.

PHLOGUS, in *Botany*, a name given by some of the ancients to several species of the *iris* and *gladiolus*, and by some to the *flammula jovis*, a sort of clematitis, so called because of the violent heat of its leaves to the taste.

PHLOMIS, in *Botany*. See SAGE *tree*.

PHLOMON *Sephanmaticon*, in the *Botanical Writings of the Ancients*, a name given to the common white mullein. The upper part of the thyrsus, or spike of flowers of this plant, was frequently used in the garlands and coronæ of the ancients; and it is named by Dioscorides and others among the yellow flowers in general use on that occasion.

PHLOX, *Sybatica*, or *hastard hyacinth*, in *Botany*, a genus of the *pentandria monogynia* class: its characters are, that the corolla is hypocrateriform, the filaments unequal, the stigma trifid, the calyx prismatic, and the fruit a capsule containing three cells, and a single seed. There are ten species.

PHLYACOGRAPHIA, formed from φλυαξις, *to trifle*, or φλυαξ, *trifler*, of φλυω, among the *Ancients*, a merry and burlesque imitation of some grave and serious piece; particularly a tragedy travestied into a comedy.

The *phlyacographia* was the same thing with the HILARODIA, or *hilarotragedy*.

There were several kinds of *phlyacography*, which had their several names. See Salmasius on Solin.

The parodies, which have been made of some parts of the best poets, as the Virgil Travesty of Scarron and Cotton; the Rival Queens of Cibber, from the Rival Queens of Lee; and some pieces of operas, the music whereof is applied to low and ridiculous words, are comprehended under the notion of *phlyacographies*.

PHLYCTÆNÆ, Φλυκταινα, formed of φλυω, *I am hot*, little white itching pimples, or vesiculæ, arising on the skin, chiefly between the fingers, and about the wrist; and full of a limpid serum.

These sometimes degenerate into the itch, and sometimes into tetters. They are cured like other cutaneous eruptions.

PHLYCTÆNÆ also denote little ulcerous vesicles, arising sometimes on the adnata, and sometimes on the cornea, of the eye, like so many little bladders full of water: they are popularly called *blisters on the eyes*.

They appear like grains of millet; and, when produced by a sharp corroding humour, occasion violent pain: the pustules on the adnata are red; those on the cornea are blackish, if near to the surface; but whiter, if deeper.

They are cured by discutients and driers.

PHLYSIS, a term used by the ancients to express an eruption on the skin, from a redundance of humours.

PHLYSTÆNÆ, formed from φλυω, φλυζω, *vhallio, I boil, bubble*, &c. in *Medicine*, a disease which produces buboes, or tumors, full of a serous humour.

The *phlysteena* is a virulent disease. The buboes it occasions are sometimes large, livid, pale, black, or of any colour different from that of the natural flesh; and, when pierced, the flesh frequently appears ulcerated under them.

They are usually occasioned by a hot, sharp humour; and arise on all parts of the body; but they are most dangerous on the cornea of the eye.

PHLYZATION, a pustule or inflammation on the skin, or the blisters arising on it after being burnt or scalded with a hot liquor.

PHOBOS, *Fear*, in *Mythology*, was personified by the Greeks, and represented with the head of a lion. See FEAR.

PHOCA, in *Zoology*, a genus of the order of *feræ*, and class of *mammalia*, in the Linnæan system: its characters are, that the number of fore-teeth in the upper jaw is six, which are parallel, the exterior being larger than the others; in the lower jaw there are four, parallel, distinct, equal and a little obtuse; there is one canine tooth in each jaw, though Pennant reckons two; the grinders are five or six, which have three points; there are no external ears, and the hind feet are palmated. To this genus belong three species, viz. the SEA-*bear*, the SEA-*lion*, and SEA-CALF.

Dr. Parsons derives the generic name *phoca*, from φωκη, or according to Dr. Charleton, from φωκη, signifying a noise or kind of grunting made by these animals. He also reduces to this genus the MANATI, the SOIE OF SEAL, and the WALRUS or *morse*. Phil. Transf. vol. xlviii. p. 160, &c.

PHOCÆNA. See PORPESSE.

PHŒBUS, in *Mythology*, a name given to APOLLO.

PHŒNICIAN *character*. See CHARACTER.

PHŒNICOPTERUS, in *Ornithology*, a genus of the *grallæ*, in the Linnæan class of birds; of which there is one species. See FLAMINGO.

PHŒNICOPUS *gallinula*, in *Ornithology*, a name by which some authors have called a bird, more usually known by the name FRINGA.

PHŒNICURUS, Φοινικουρος, in *Ornithology*, a name by which the ancient naturalists called the *ruticilla*, or REDSTART.

PHŒNIGMUS, Φοινιγμος, formed from φοινιξ, *red*, a medicine which produces redness, with blisters, on the places it is applied to.

Such are mustard-seed, pepper, vesicatories, &c.

Phanigmi are used to draw the humour to the part they are applied on, and to divert it from the part affected.

PHŒNIX, Φοινιξ, in *Astronomy*, a constellation of the southern hemisphere; unknown to the ancients, and invisible in our northern parts.

The number of stars in this constellation is thirteen; the situation, longitude, latitude, and magnitude of which are as follow:

Names and situations of the stars.	Signs	Longitud. °	′	″	Latitude. °	′	″	Magnitude.
In the bright head	♑	0	1	1	0	1	1	2
		1	35	57	10	53	45	
In the neck		10	38	20	11	15	41	4
In the corner of the right wing		5	46	10	41	54	38	3-4
S. of three in right wing.	♒	29	47	46	38	49	12	4

Under the right wing 1st		1	24	0	54	24	16	3-4
2d		8	27	38	55	5	23	4

This conſtellation took its name and form from that of a bird famous among the ancients; but generally looked upon by the moderns as fabulous.

The naturaliſts ſpeak of this bird as ſingle, or the only one of its kind: they deſcribe it as of the ſize of an eagle; its head finely creſted, with a beautiful plumage; its neck covered with feathers of a gold colour, and the reſt of its body purple; only the tail white, intermixed with carnation; and its eyes ſparkling like ſtars. They hold, that it lives five or ſix hundred years in the wilderneſs; that, when thus advanced in age, it builds itſelf a funeral pile of ſweet wood, and aromatic gums; then it fires it with the waſting of its wings, and thus burns itſelf; and from its aſhes ariſes a worm, which, in time, grows up to be another *phœnix*.

Hence the Phœnicians gave the name *phœnix* to the PALM-*tree*; becauſe, when burnt down to the very root, it naturally riſes again fairer than ever.

Ancient hiſtorians reckon four appearances of the *phœnix*, the firſt, in the reign of Seſoſtris; the ſecond, in that of Amaſis; the third, in that of the third Ptolemy; and the fourth, according, to Dion Caſſius, as a preſage of the death of Tiberius, but Tacitus refers it to Egypt under the empire of Tiberius, and Pliny to the conſulate of Quintus Plancius, which took place A. D. 36.

The ancients, however, ſpeak of the *phœnix* as a fabulous bird.

The ancient Chriſtians refer to the *phœnix* in ſome of their accounts of the reſurrection.

PHŒNIX, in *Botany*, a name given by medicinal writers to the graſs called *lolium rubrum*, and in Engliſh, *ray-graſs*.

PHŒNIX is alſo the name given by Kæmpfer and Linnæus to a genus of plants in Linnæus's Appendix, called by others *elate* and *kurzuindeli*. The characters are theſe: it produces ſeparate male and female flowers, in both the whole ſpatha ſerves for a cup which is divided into three parts, and the petals are three in both; in the male the petals are of an oval figure and concave; the ſtamina are three ſlender filaments, and the antheræ are very ſhort: in the female flower the germen of the piſtil is of a roundiſh figure; the ſtyle is ſhort and pointed, and the ſtigma is acute; the fruit is an oval drupe, having only one cell; this contains one ſeed, which is of a bony hardneſs, and of an oval figure, with a deep longitudinal furrow reaching from one end to the other. There is only one ſpecies. See PALM-TREE.

PHŒNIX, *penis*, among the *Ancients*, a muſical inſtrument not unlike the CITHARA.

PHŒOPUS, in *Ornithology*, a name uſed for two different birds: the one called by the Germans *brachvogel*, and the other the *wilmbrell*, or *aquata minor*, the ſmall curlew of authors.

The firſt of theſe, or the *brachvogel*, is of a deep black colour, ſpotted with a yelloviſh and reddiſh brown; its beak is long, ſlender, and black, and is moderately bent; its neck is grey, tending to reddiſhneſs towards the bottom, and its belly is white. Mr. Ray ſuſpects this not eſſentially to differ from the other, but the ſight of the bird alone can determine that.

PHOLAS, in *Natural Hiſtory*, the name of a genus of *ſhells* belonging to the *teſtacea* order in the claſs of worms, in the Linnæan ſyſtem; the characters of which are theſe: its animal is an aſcidia; the ſhell is bivalve, opening wide at each end, with ſeveral leſſer ſhells at the hinge; the hinges fold back and are united by a cartilage; beneath the hinge in the inſide there is an incurvated tooth. Linnæus enumerates ſix ſpecies. See *Tab. of Shells*, N° 29.

The word *pholas* is derived from the Greek φωλεὸς, and ſignifies no more than any thing which is hidden; the name was given to this genus of ſhell-fiſh from their cuſtom of making themſelves holes in earth, ſand, ſtones, or wood, and living hidden in them. Many being of opinion, that theſe could not work themſelves into the ſubſtance of hard ſtones, have thought that they were hatched in holes accidentally formed in ſtones, and that the ſhells naturally grew of ſuch a ſhape as was neceſſary to fill the cavity. Nor is this the only error propagated concerning the *pholas*; for as all that was ſignified by the name being only that the ſhell was hidden in ſome ſolid ſubſtance, whenever an author found a ſhell-fiſh of whatever kind thus buried in ſtone, he deſcribed it under the name of *pholas*.

There are many ſpecies of the ſhell-fiſh, and theſe of ſeveral different genera, which thus hide themſelves in ſtone; and theſe have therefore been called by different authors *pholades*; and hence it has been ſaid, that the *pholas* was in ſome ſpecies a bivalve, and in others a multivalve ſhell. The true *pholas*, which Liſter has very well deſcribed, is a genuine multivalve, being compoſed of five pieces; but this is a very ſcarce fiſh, and ſeveral of the muſcles and of the chamæ being often found in ſtone, they have all been called bivalve *pholades*; and ſuch as have found the chamæ thus immerſed, and found them really to conſiſt of only two ſhells, have cenſured the authors of error who have deſcribed the *pholas* as having five. Hiſt. Nat. Eclaire. p. 362.

All the ſpecies of ſhell-fiſh which are found in ſtone have certainly been the means of making the holes in which they are found: the fact is inconteſtible, but the means yet wholly unknown. Perhaps, when ſome accurate obſerver ſhall have an opportunity of examining the fiſh alive, the myſtery will be cleared up. All that we know at preſent is, that they are firſt buried in the ſtone while very ſmall; ſince the aperture on the ſurface of the ſtone is uſually much ſmaller than the diameter of the ſhell contained within, and only ſerves to admit the ſea-water, or to give paſſage to the probocſeis of the incloſed fiſh.

As to the luminous quality of this ſpecies of ſhell-fiſh, obſerved by Pliny and by modern naturaliſts, ſee DACTYLUS.

For an account of a particular ſpecies of *pholas*, called by Dr. Parſons *pholas conatus*, by others *pholas lignarum*, and in Dutch wood-muſcle, becauſe it is found burrowed in timber, ſee Phil. Tranſ. vol Ix. p. 1. &c.

PHOLIS, in *Natural Hiſtory*, the name of a genus of foſſils of the claſs of the gypſums or plaiſter ſtones, the diſtinguiſhing characters of which are, that the bodies of it are conſiderably hard, compoſed of ſomewhat broad particles, and of a bright cryſtalline luſtre.

The word is derived from φολὶς, *a ſcale*, or *ſmall flake*, from theſe bodies being compoſed of particles of that form.

The ſpecies of this genus are the moſt valuable of all the gypſums, as burning to the beſt and fineſt plaiſter, but ſo far as is yet known there are but two of them: the fine plaiſter-ſtone of Montmartre in France, called by us *plaiſter of Paris ſtone*, and *parget*; and the other the coarſer and ſomewhat reddiſh kind, common in many parts of England, and called *bull plaiſter*. Hill. See PARGET.

PHOLIS, in *Ichthyology*, the name of a ſmall anguilliform fiſh, the back of which is brown, the belly white, and the whole back and ſides ſpotted, and the ſkin ſoft and not covered with ſcales, but with a tough mucilaginous matter like the eel.

This moſt of all approaches to the *alauda*, and though uſually ſomewhat larger, yet Mr. Ray doubts whether it really differs from it in any thing eſſential; its great diſtinction being its colour, which, though a very obvious, is a very precarious one.

PHOLLIDES, a word uſed by the ancient phyſicians for ſoft and fungous tumors of the legs, ſuch as thoſe of people in an anaſarca, or leucophlegmacy.

PHOLLIS, as a *coin*. See FOLLIS.

PHONASCIA, Φωνασκια, derived from φωνη, *voice*, the art of forming the human voice.

In ancient Greece, there were combats or contells eſtabliſhed for the voice, as well as other parts of the gymnaſtice.

The combats continued to be held in the time of Galen; and they were theſe that brought the *phonaſcia* into vogue. Hence the maſters of this art, and thoſe who taught the art of managing the voice, were called *phonaſci*, φωνασκοι; and under their tutorage were put all thoſe deſtined to be orators, ſingers, comedians, &c.

PHONICS, Φωνικη, derived from φωνη, *voice*, or *ſound*, the doctrine or ſcience of SOUNDS; otherwiſe called ACOUSTICS.

Phonics may be conſidered as an art analogous to optics; and may be divided, like that, into *direct*, *refractive*, and *reflected*. Theſe branches the biſhop of Verni, in alluſion to the parts of optics, denominates *phonics*, *diaphonics*, and *cataphonics*.

Phonics is improveable, both with regard to the object, the medium, and the organ.

As to the object, ſound, it may be improved, both with regard to the production and the propagation of ſounds.

The firſt, in ſpeaking or pronouncing, in whiſtling or ſinging, or hallooing, or luring, which are all diſtinct arts, and all improveable. The ſecond, by the poſition of the ſonorous body.

With regard to the medium, *phonics* may be improved by the thinneſs and quieſcency thereof, and by the ſonorous body being placed near a ſmooth wall, either plain or arched, eſpecially cycloidally or elliptically: whence ariſes the theory of whiſpering places.

Add to theſe, that by placing the ſonorous body near water, its ſound is mollified; that, by placing it on a plain, the ſound is conveyed to a greater diſtance than on uneven ground, &c.

As to the organ, which is the ear, it is helped by placing it near a wall, eſpecially at one end of an arch; the ſound beginning

beginning at the other), or near the surface of water, or that of the earth.

Alſo by inſtruments, as the ſtentorophonicon, or ſpeaking-trumpet.

Alſo by an inſtrument to help weak ears, as ſpectacles do eyes; by an inſtrument to take in vaſtly remote ſounds, as teleſcopes do objects; by a microphone, or magnifying ear-inſtrument; and by a polyphone, or multiplying ear-inſtrument.

Catophonics, or reflected hearing, may be improved by ſeveral kinds of artificial echoes; for, in general, any ſound falling, either directly or obliquely, on any denſe body of a ſmooth ſurface, whether plain, or arched, is beat back again, or reflected; i. e. it echoes more or leſs. See ECHO.

PHONICUM *centrum*. See CENTRUM.

PHONOCAMPTICUM *cornu*. See CORNU.

PHORBÆA, or PHORBEIA, in the *Muſic of the Ancients*, a name given to a ſort of *frenum*, or *bandage*, applied to the mouths of people who played on the pipe.

It was a ſort of leather band, which went firſt acroſs the forehead, then behind each ear, and from thence making one or two turns round the head, it paſſed over the mouth, where its office was to reſtrain the lips from emitting too much breath at once, and cauſe them to diſcharge only juſt ſo much as would ſerve to inflate the pipe.

Simonides, deſcribing the trial of ſkill between Marſyas and Apollo, mentions this *phorbeia* or *capiſtrum*; and ſome antique gems, yet remaining among us, have the figure of a Marſyas's head, with the *phorbeia* upon it.

By the different ſtructure of the *phorbeia*, as expreſſed on the different coins, we find, however, that there were two ſpecies of it; the one was leſs complex, conſiſting only of a perpendicular piece down the cheek, and a tranſverſe one, running acroſs the lips, and covering the whole orifice of the mouth, only leaving a hole cut through it, at which the mouth-piece of the pipe was to be put in. The other conſiſted of ſeveral bandages, as at firſt deſcribed, and the lower tranſverſe piece of theſe did not come over the mouth, but only bore up the lower lip in a forcible manner, againſt the upper.

The old Greek writers diſtinguiſhed theſe by two different names added to the original word *phorbeia*; the firſt, or ſimple one, was called *monomeres*; and the other, or more complex one, *diomeres*: they were both called alſo, by Soranus, and others, *epideſma*, and ſometimes ſimply *deſma*. Soranus de Epideſmis.

PHORIMOS, a name given by ſome authors to *rach* ALLUM.

PHORINE, a word uſed by ſome authors to expreſs the ſkin of a hog, ſome alſo underſtand it to mean a ſkin of any kind, extending it even to the human cutis.

PHORMIX, among the *Ancients*, the ſame with CITHARA.

PHORMORAPHIS, in the *Materia Medica*, a name often uſed by the later Greek writers, and generally looked on as one of their unintelligible words, or the name of ſome drug not known at this time. See CARPESIA.

PHORONOMIA, derived from φορὰ, *motion*, and νόμος, *law*, is a ſcience comprehending the laws of motion, both of ſolids and fluids. The work of Hermannus, printed at Amſterdam in quarto, in 1715, under this title, is well known.

PHOS, a word uſed by ſome medical writers to expreſs a diſtemperature of the eye, in which there is ſeen a black circle wholly ſurrounding the pupil.

PHOSCAS, in *Ornithology*, the name of a freſh-water fowl of the duck kind, and of the ſize of the common wigeon. Its body is remarkably flat; its beak and legs are blue; its head and neck are of a brownith colour, variegated all over with numerous triangular black ſpots.

PHOSPHORIA, φωσφόρια, in *Antiquity*, a feſtival in honour of Phoſphorus or Lucifer.

PHOSPHORICAL *column*. See COLUMN.

PHOSPHORUS, φωσφόρος, formed from φῶς, *light*, and φέρω, *I bear*, a matter, which ſhines, or even burns, ſpontaneouſly, and without the application of any ſenſible fire.

Phoſphori are either *natural*, or *artificial*.

PHOSPHORI, *natural*, are matters, which become luminous at certain times, without the aſſiſtance of any art or preparation.

Such are the glow-worms, frequent in our colder countries; lantern-flies, and other ſhining inſects, in hot countries; rotten-wood; the eyes, blood, ſcales, fleſh, ſweat, feathers, &c. of ſeveral animals; diamonds, when rubbed after a certain manner, or after having been expoſed to the ſun or LIGHT; ſugar and ſulphur, when pounded in a dark place; ſea-water, and ſome mineral waters, when briſkly agitated; a cat's or horſe's back, duly rubbed with the hand, &c. in the dark; nay, Dr. Croom tells us, that upon rubbing his own body briſkly with a well-warmed ſhirt, he has frequently made both to ſhine; and Dr. Sloane adds, that he knows a gentleman of Briſtol, and his ſon, both whoſe ſtockings will ſhine much after walking.

All natural *phoſphori* have this in common, that they do not ſhine always; and that they never give any heat.

The natural *phoſphori* are either foſſile, vegetable, or animal.

The foſſile are, though very different in degree, ſome ſorts of earths, white ſand, lime-ſtones, ſtalactites, and ſeveral other figured ſtones, iſland cryſtals, flints, ſome ſpecies of agates, white arſenic; but no ſort of metals, metallic or ſulphureous bodies, as jet, amber, except the before mentioned arſenic.

On the other hand, ſalts imbibe light, provided they are diveſted of every metallic principle; otherwiſe not, though as pellucid as poſſible. For this reaſon none of the vitriols will imbibe light; but other ſalts will, though with a conſiderable difference as to quantity; for fal gem and rock ſalt imbibe very little; ſea ſalt, if dry, and in cryſtals, much more; and, in like manner, ſal ammoniac, ſal catharticum, and nitre yet more. This power is weak in the natron of the ancients, and alum; but brighteſt of all in borax.

In the vegetable kingdom we find very few *phoſphori*; that of dry rotten wood is weak and not laſting; it appears chiefly upon the edges and inequalities of the ſurface. But this is moſt remarkable in the rotten wood of the fir-tree, and ſome others, where, in the dark, you ſee ſhining ſpots as big as tares; whereas in full light the whole ſurface appears alike. Some few barks are luminous, but not conſiderably ſo; but no fruits, ſeeds, or their meals. Cotton, and the cryſtals of tartar, appear very bright, but fine loaf-ſugar appears the moſt luminous of all, both without and within; gums and reſins retain no light.

There is a vaſt variety of *phoſphori* in the animal kingdom, ſuch as the bones and teeth; to theſe may be added the ſhells of fiſh, egg-ſhells, the human calculus, bezoar, and thoſe parts of animals in which the terreſtrial principle is very predominant. But where there is a conſiderable quantity of oily matter, as in the hoofs, horns, and feathers, no light is manifeſt, or at leaſt in a ſmall degree. Light is viſibly retained by the ſkins of ſeveral living animals. Water cannot be made to imbibe light, though ice does exceedingly well, and eſpecially ſnow.

Beccarius propoſes ſome queries concerning the natural *phoſphori*, of which the firſt is, in what and how great a light the object ought to be placed? He tried different *phoſphori* in different degrees of light, and found them imbibe moſt light from the ſun itſelf; next in quantity when the ſky was clear; and the leaſt in foggy weather. Theſe experiments ſhould be made in the open air, and not in a houſe with the glaſs-windows ſhut; becauſe many bodies appear luminous when the light has come directly to them, which will not have that appearance when the light has paſſed through the glaſs. He laſtly tried what light they would imbibe from very bright flame, and found that alabaſter itſelf, which is ſaturated more than any ſubſtance by the ſun's rays, imbibed exceedingly little. The next query is, how long theſe bodies ſhould remain in the light to be ſufficiently ſaturated? Four or five ſeconds were found the utmoſt length of time required for that purpoſe. The other query is, how long the received light will continue in theſe *phoſphori*? It does not laſt the ſame time in all; but continues more or leſs, from two ſeconds to eight, in proportion to the ſtrength of the *phoſphorus*, and the quantity of light received.

But that which, of all natural *phoſphori*, has occaſioned the greateſt ſpeculation, is the

PHOSPHORUS, *barometrical*, or *mercurial*. M. Picard firſt obſerved, that the mercury of his barometer, when ſhaken in a dark place, emitted light; with this circumſtance, that, in ſhaking the mercury with rapidity, ſometimes above, and ſometimes below its equilibrium with the air, the light was only ſeen when below it, where it appeared as if adhering to the upper ſurface.

But this light is not found in the mercury of all barometers; which occaſions a great difficulty.

M. Bernoulli, upon examining the circumſtances of this phenomenon, invented a ſolution of the ſame: he imagines, that upon the mercury's deſcending, the vacuum in the tube increaſing, there iſſues out of the mercury, to fill up this exceſs of vacuity, a very fine ſubtile matter, before diſperſed throughout the pores of this mineral; and that, at the ſame time, there enters through the pores of the tube another fine matter: thus, the firſt matter emitted from the mercury, and collected over its ſurface, ſtriking impetuouſly againſt that received from without, has the ſame effect with Deſcartes' firſt element againſt the ſecond; that is, it produces the motion of light.

But why, then, is not the phenomenon common to all barometers? To this he answers, that the motion of the subtile matter out of the mercury may be weakened, and prevented, by any heterogeneous matter collected on its upper surface, into a kind of pellicle, so that the light should never appear, but when the mercury is perfectly pure. This reasoning seemed confirmed from the experiments of several barometers, which he made according to this plan; but the Royal Academy of Sciences, repeating experiments with barometers made after the same manner, did not meet with the same success; the light being found in some, but not in others.

M. Homberg, therefore, conjectured, that the difference consisted in the different qualities of the quicksilver: in some, he observed, they used quick-lime to purify it; in others, steel-filings. The mercury, then, rising in the distillation, and passing through the lime, might take away some parts thereof, capable, by their extreme smallness, of lodging in its interstices.

Hence, as quick-lime always retains some fiery particles, it is possible, in a place void of air, where they swim at liberty, they may produce this lustre.

Mr. Hauksbee has several experiments on the mercurial *phosphorus*. Passing air forcibly through the body of quicksilver, placed in an exhausted receiver, the parts were violently driven against the side of the receiver, and gave all around the appearance of fire; continuing thus till the receiver was half-full again of air.

From other experiments he found, that though the appearance of light was not producible by agitating the mercury in the same manner in the common air, yet that a very fine medium, nearly approaching to a vacuum, was not at all necessary.

And, lastly, from other experiments he found, that mercury inclosed in water, which communicated with the open air, by a violent shaking of the vessel wherein it was inclosed, emitted particles of light in great plenty, like little stars.

By including the vessel of mercury, &c. in a receiver, and exhausting the air, the phenomenon was changed; and, upon shaking the vessel, instead of sparks of light, the whole mass appeared one continued circle of light.

Farther, if mercury be inclosed in a glass tube, close stopped, that tube is found, on being rubbed, to give much more light, than when it had no mercury in it. When this tube has been rubbed, after raising successively its extremities, that the mercury might flow from one end to the other, one sees a light creeping in a serpentine manner all along the tube; that is to say, the mercury is all luminous. The mercury, being made to run along the tube afterwards without rubbing it, was found to emit some light, though much less than before; this proves that the friction of the mercury against the glass, in running along, does in some measure electrify the glass, as the rubbing it with the hand does, only in a much less degree. This is more plainly proved by laying some very light down near the tube, for this will be attracted by the electricity raised by the running of the mercury, and will rise to that part of the glass along which the mercury runs; and it is very plain from this, that what has been long known in the world under the name of the *phosphorus* of the barometer is not a *phosphorus*, but merely a light raised by electricity, the mercury electrifying the tube. Phil. Trans. N° 484. See ELECTRICITY and MERCURY.

PHOSPHORUS, *artificial*, are such as owe their luminous quality to some art or preparation.

Phosphori are, it is well known, often produced by art; some are made by the maceration of plants alone, and without any fire; such as thread, linen cloth, but above all paper. The luminous appearance of this last, which is now known to be an electrical phenomenon, is greatly increased by heat. This is confirmed by two experiments; the first is, by exposing the paper, spread upon an iron grate, to the naked fire, yet not near enough to scorch it, and then laying a warm brick thereon to retain the heat; by which means it was observed, that where the paper was not screened by the iron-grate, it was most luminous; so that by the lights and shades you might distinguish in the dark the image of the iron-grate a considerable time. The other experiment is, the application of the paper to a plate of warm brass; from which, when in the dark, you might very easily, by its being less luminous, distinguish the margin of the paper that had not been warmed by the brass.

However Beccarius, though he acknowledges that paper, after having been made red-hot and cooled again, is an excellent *phosphorus*, found, that it was much injured by being exposed to the light of the sun. He made experiments to the same purpose with a great variety of substances, mineral, vegetable, and animal; and observed, that the effects were the same, and that the stronger the light was, and the longer they were exposed to it, the more injury they received: and he found also, that the injury they received was lasting.

The same author takes notice also of those *phosphori* which become so by the assistance of fire; but the fire here spoken of is not great enough to dissolve their constituent parts, but only such as may affect the external parts of their texture, and that but gently; so that the process here mentioned is only drying or roasting. For it is not the watery or the saline parts in bodies which are torrified, but the oleaginous, wherewith many vegetables, and most animals abound. The white flesh of animals, such as that of chickens, become a *phosphorus* by roasting, as well as the tendons; and whatever parts of animals become gluinous by boiling, such as carpenters glue, isinglass, &c. to these may be added cheese. Bones, though they imbibe light without any preparation, have that property in a much greater degree when burnt, and their luminous appearance is much more lively. But roasting has not this effect upon feathers, hoofs, horns, and only in a small degree on whites of eggs, though the yolk when dry easily became a *phosphorus*.

The same operation which produces several *phosphori* from the animal kingdom, gives also several from the vegetable. Thus, by gently toasting gums, as myrrh, gum tragacanth, and others, they appear luminous, though different in degrees; and this light is clear in proportion to the gentle evaporation of their aqueous parts. By this treatment nuts of every kind, pulse, corn, coffee-berries, meal, bread, and wafers, also become *phosphori*. Turpentine, amber, and some resins, require more fire before they imbibe light; so that you must dissolve them of their acid, and their light ethereal oil, to make them appear luminous. But here great care must be taken that they boil no longer than from being white they turn yellow; for, if you proceed longer, your labour is lost. These *phosphori* produced by torrefaction soon lose their power, which, perhaps, neither time, nor a thorough dissolution of their parts, can deprive the natural ones of. In general, as long as the *phosphori* gained by torrefaction, preserve their power, their light is more sharp and striking, but the natural more weak. Those that are gained by calcination, and Baldwin's *phosphorus*, seem to possess both the striking light of these gained by torrefaction, and the weaker light of the natural *phosphori*: the last they preserve a long time, but the former is lost by degrees much sooner. The well calcined ashes of plants, or rather their terrestrial parts, remaining after the solution of their fixed salts by washing, and neutral salts, continue *phosphori* after many years: so that, as far as we can judge, the luminary power which is gained by calcination, though not so intense, continues perpetual; whereas that gained by torrefaction always decreases, and in a very little while is no longer visible. Some, even by this method, continue to imbibe light much longer than others. Gum arabic, which continues longest, fails six days; bread not one, and coffee only a few minutes. However, at any time, by a fresh torrefaction, you may recover these languid *phosphori*; in which property they have great likeness to the Bolognian stone, and other *phosphori* prepared by art.

Almost all bodies, by a proper treatment, have that power of shining in the dark, which, at first, was supposed to be the property of one, and afterward only of a few. How this is brought about is not easy to solve. If we suppose, with some, that the light from a luminous body, enters and abides in the *phosphori*, we shall find somewhat new to admire in light itself. It is no new opinion, that this fluid consists of very fine particles, which are continually darted forth from a luminous body in all directions, with a very great velocity; but it has by no body been laid down hitherto, that these particles are not dissolved by the violence of their agitation, nor dispersed, nor immediately cease to exist; but subsist still, and adhere to what bodies come in their way, as heat does. If therefore the particles of light are not dissolved as soon as they are emitted from a radiant body, but continue some time, what else is required but that we allow its atmosphere to every lucid appearance? If the *phosphori* shine with a borrowed light, but not with their own, and that only when put in motion, and fired by the rays of a shining body, which some experiments seem to confirm, then other new doctrines will arise. There must be then a hidden, a secret principle in bodies, to be lighted up by this most subtile fire. There will be in the universe a certain perpetual fire from these *phosphori*; the matter of which, though constantly dissipated by burning, does not waste enough to be obvious to our senses. See Phil. Trans. N° 478, in vol. xliv. art. 17. p. 83. and Beccarii Com. p. 52, 91, &c. See LIGHT, *Light from Diamonds*, and *Bolognian* PHOSPHORUS, *infra*.

Of artificial *phosphori* there are three principal kinds: the first

firſt *burning*, which conſumes every combuſtible it touches: the other two have no ſenſible heat; and are called the *Bononian* and *Hermetic phoſphorus*, to which claſs other of a ſimilar kind may be reduced.

PHOSPHORUS, *the burning*, which is a combination of phlogiſton with a peculiar acid, and, conſequently, a ſpecies of ſulphur, tending to decompoſe itſelf, and ſo as to take fire on the acceſs of air only, may be made of urine, blood, hairs, and generally of any part of an animal, that yields no oil by diſtillation. The matter it is moſt eaſily drawn from is human urine. It is of a yellowiſh colour, and of the conſiſtence of hard wax, in the condition it is left by the diſtillation; and, in this ſtate, is called *phoſphorus fulgurans*, from its coruſcations; and *phoſphorus ſmaragdinus*, becauſe its light is frequently green or blue, eſpecially in places that are not very dark. It is alſo called *ſolid phoſphorus*, from its conſiſtence.

It diſſolves in all kinds of diſtilled oils; and, in that ſtate, is called the *liquid phoſphorus*.

It may be ground in in all kinds of fat pomatums; in which caſe, it makes a luminous unguent.

So that the *phoſphorus fulgurans, ſmaragdinus, ſolid and liquid phoſphorus, and luminous unguent*, are all the ſame preparation, under different circumſtances. See FULGURATING *Phoſphorus*.

The diſcovery of this *phoſphorus* was firſt made in 1677, by one Brandt, a citizen of Hamburgh, in his reſearches for the philoſophers ſtone. Brandt communicated the ſecret to one Kraaft, of Dreſden, but with-held it from Kunckel; upon which this chemiſt, knowing that urine was the ſubſtance employed, ſucceeded in his attempts of making *phoſphorus*; accordingly, this *phoſphorus* is commonly called *Kunckel's phoſphorus*, after his name. A ſimilar *phoſphorus* was alſo made by Mr. Boyle, after having ſeen a piece of it in the hands of Kraaft, who brought it to London in 1679, in order to ſhew it to the king and queen of England; having been only informed that this *phoſphorus* was produced from ſome matter belonging to the human body. Kraaft, indeed, told Stahl, that he had communicated the proceſs for making it to Mr. Boyle; but this is ſuch an imputation on the integrity and honour of our Engliſh philoſopher, as can by no means be admitted on the teſtimony of a man, who had been treacherous to Kunckel, who traded in the ſecret of making *phoſphorus*, and after ſelling it to many perſons, publiſhed the proceſs for making it in the Mercure Galont, for June 1683. Kunckel, and a German chemiſt called Godfrid Hankwitz, to whom Boyle communicated the method of preparing it, were the only perſons who made it in any conſiderable quantities.

M. Hellot, in his Memoir upon this ſubject, Ac. Paris, 1737, enumerates all the proceſſes for making it, that were in uſe ſoon after the diſcovery of it: viz. that publiſhed by Mr. Boyle in 1680, in the Phil. Tranſ. N° 196. (See Phil. Tranſ. Abridg. vol. iii. p. 346). that of Kraaft; that of Brandt, in a collection of experiments and obſervations of Dr. Hooke, publiſhed by Dr. Derham in 1726; that of M. Homberg, in the Ancient Memoirs of the Academy, in 1692; and thoſe found in the works of ſeveral chemiſts, particularly of Thelckmeyer, Hoffman, and Nieuwentyt. However, the operation continued in a great degree a ſecret till the year 1737, when a ſtranger came into France, and obtained a reward from the miniſtry for communicating his proceſs, which was executed by Meſſ. Hellot, Du Fay, Geoffroy, and Duhamel. Since the publication of M. Hellot's Memoir, the operation has been no longer a ſecret; though ſeldom executed, becauſe it was rather curious than uſeful, and both troubleſome and expenſive.

PHOSPHORUS, *preparation of ſolid*, or PHOSPHORUS *of urine*. Evaporate a good quantity of urine of beer-drinkers to the conſiſtence of honey; cover it up in an earthen veſſel, and ſet it three or four months in a cellar, to ferment and putrefy. Mix two parts of ſand, or powder of pot-ſtreds, with one part of this urine, and put it into a retort, fitted to a long-necked receiver, with two or three quarts of water in it. Diſtil it in a naked fire, in a reverberatory furnace; at firſt gently; after two hours, augment the fire gradually, till all the black fetid oil be drawn off. Raiſe the fire to the higheſt degree; upon which, white clouds will come into the receiver, and fix, by little and little, on one ſide, in form of a yellowiſh ſkin; and another part will precipitate to the bottom in powder. Keep the fire thus violent for three hours, till no more fumes ariſe. Let all cool, and unlooſe the veſſels; and, throwing more water into the receiver, ſhake all well about, to looſen what ſticks to the ſides. Pour the whole into a glaſs veſſel, to ſettle.

The volatile ſalt will now diſſolve in the water, and the *phoſphorus* and oil will ſink to the bottom; then pour off the water, and gathering the remaining part together, put it into a glaſs veſſel, with a little freſh water, and digeſt it in a ſand-heat, ſtirring it from time to time with a wooden ſpatula.

By this means, the *phoſphorus* will ſeparate from the oil, and ſink to the bottom: pour off the oil, and make up the *phoſphorus*, while hot, into ſticks for uſe.

Boerhaave gives us other ways of preparing *phoſphorus*. Recent urine, he obſerves, digeſted three or four days in a tall glaſs, with a heat no greater than that of a healthy man, grows ruddy, fetid, and cadaverous; this digeſted urine, being put to diſtil in a retort, yields a clear fetid liquor, then a yellow volatile ſalt, which, evaporated to the conſiſtence of a ſapo, and mixed with four times its weight of dry ſand, and the diſtillation continued in a covered retort, there ſucceſſively comes over, by greater and greater degrees of fire, a fetid brown oil, bluiſh fumes, and, finally, a groſs ſhining matter, which ſinks in water, and is the ſolid *phoſphorus*.

To make it more eaſily, and to the beſt advantage, it may be proper to take a ſufficient quantity of human urine, afforded by a perſon not much given to drink wine, and exhale it away in anopen veſſel to a rob, or the conſiſtence of honey; then ſet it to putrefy for half a year, and, upon diſtillation, it will afford a large proportion of ſalt; after which, if ſix times its own quantity of ſand, or brick-duſt, be added to the remainder, and the diſtillation be continued, as in the caſe laſt mentioned, the *phoſphorus* will fall into the water. Or it may commodiouſly be prepared, by ſuffering the rob of urine to digeſt for two years in an open veſſel in the open air; during which time, a ſliny, feculent, unctuous, earthy matter, will fall to the bottom; which, being frequently waſhed with pure water, wherein it will not diſſolve, will leave a white matter behind it, neither of an alkaline, acid, ſaline, or terreſtrial, nor ſcarce of an unctuous nature: and this is of itſelf a proper matter for the making of *phoſphorus* by diſtillation with ſand.

In order to preparing the *phoſphorus*, and indeed moſt of the other preparations of urine, the firſt ſtep is to reduce that liquor to the conſiſtence of a rob or thick extract; thoſe who have worked on this ſubject ſufficiently know, how abominably naſeous and diſagreeable a taſk this is. The operator alone is not the perſon who is almoſt poiſoned by it, but the whole neighbourhood is affected; and it is well known, that our Godfrey, who uſed to prepare large quantities of this ſubſtance, was always obliged to keep a houſe in the fields to perform this part of the proceſs in.

There is an eaſy and excellent method propoſed by Stahl for the performing this troubleſome buſineſs, by means of condenſation by cold or freezing. There needs no more than to expoſe the proper quantity of urine to ſome froſty nights in winter; or at any time of the year to our ice-houſes, or other places where ice is preſerved all the year round. The froſt will, in this caſe, affect a large part of the urine, but not the whole; and the liquid part being ſeparated from the ſolid ice, it will be found that the watery parts alone have ſuffered the freezing, and that all the unctuous and ſaline ones are left behind in the unfrozen part, which is, by repeated freezings of its yet remaining aqueous parts, at length reduced to that ſort of rob which is required for all the purpoſes of diſtillation, and that without any trouble or offenſiveneſs, either to the operator or any body elſe. The power of condenſation by freezing in this manner, extends to wine, vinegar, and all fermented liquors; but it operates differently on the ſeveral different ones, and is to be regulated according to their natures. The natural cold of our climate is ſeldom too great for any of the liquors we deſire to condenſe; that is, it is never ſo great as to condenſe the whole into ice. It often is not ſufficiently great to condenſe the aqueous part, even after ever ſo many repetitions. In this caſe, it may be proper to bring in the uſe of the common freezing mixtures, made with ice, or ſnow and ſalt. To ſuit the artificial degree of cold, in theſe caſes, requires care and experience, and is almoſt as nice a point as the ſuiting the degrees of heat in the operations of chemiſtry.

In 1743, Mr. Margraaf publiſhed, in the Memoirs of the Academy at Berlin, a new and excellent proceſs for obtaining more eaſily and expeditiouſly, and at leſs expence than has hitherto been done, a conſiderable quantity of *phoſphorus*. In his proceſs, a kind of plumbum corneum is previouſly prepared, by diſtilling a mixture of four pounds of minium with two pounds of powdered ſal ammoniac; the reſiduum after the diſtillation, or the plumbum corneum, is to be mixed with nine or ten pounds of extract of putrefied urine, boiled to the conſiſtence of honey. This mixture is to be made ſlowly in an iron cauldron ſet upon the fire, and by frequently ſtirring the contents. Half a pound of powdered charcoal is then

then to be *added*, and evaporation is to be continued till the whole is reduced into a black powder, which is to be put into a retort, in order to extract from it, by a moderate and gradual heat, all the volatile products of urine, that is, volatile alkali, fetid oil, and an ammoniacal matter which adheres to the neck of the retort. In this diſtillation the heat is only to be raiſed ſo as to make the matter red-hot. After the diſtillation a black and friable reſiduum is left, from which the *phoſphorus* is to be extracted by a ſecond diſtillation, and a ſtronger heat. Before it is expoſed to another diſtillation it may be freed by throwing ſome of it upon hot coals. If the matter has been well prepared, a ſmell of garlic exhales from it, and a blue phoſphoriſcal *flame* is ſeen undulating along the ſurface of the hot coals. This matter is to be put into a good earthen retort, capable of ſuſtaining a violent fire, and which may be ſecured with a covering of clay and hair. Three quarters of the retort are to be filled with the matter which is to yield the *phoſphorus*. It is to be placed in the common furnace for diſtillation with a retort; excepting that inſtead of being terminated by an ordinary reverberatory or dome, this ought to be terminated by the upper piece of an air-furnace, to which a tube is to be applied, the diameter of which ought to be from four to ſix inches, according to the ſize of the furnace, and the height from eight to nine feet. This apparatus, which *Mr.* Beaume uſes, is neceſſary for raiſing a ſufficient heat, and for the convenience of throwing in a ſufficient quantity of fuel through the door of the upper piece of the furnace. The retort ought to be well ſuited to a receiver of moderate ſize, pierced with a ſmall hole, and half full of water. For this purpoſe ordinary fat lute may be bound on with ſtrips of linen, dipped in a lute prepared with lime and whites of eggs. The hole in the furnace through which the neck of the retort paſſes ought to be well ſtopped with furnace earth. Laſtly, a ſmall wall of bricks is raiſed betwixt the furnace and the receiver, to guard this veſſel againſt heat as much as is poſſible.

All theſe preparations being made the evening before the diſtillation is to be performed, we are then capable of proceeding to this operation, which is very eaſy. The retort is to be heated by ſlow degrees during an hour and a half; and then the heat is to be increaſed till the retort be red-hot, and the *phoſphorus* begin to paſs in luminous vapours: when the retort is almoſt of a white-red heat, the *phoſphorus* paſſes in drops, which fall and congeal in the water at the bottom of the receiver. This degree of heat is continued till no more paſſes into the receiver. When a retort contains eight pints or more, this operation continues about five hours.

Mr. Margraaf's apparatus is ſomewhat different from that above deſcribed. He divides the whole quantity of matter from which the *phoſphorus* is to be obtained into ſix ſmall retorts, which he places in a furnace that he deſcribes. The advantage of this diviſion is, that if any accident happens to one retort, the whole matter is not loſt; and as the retorts are ſmaller, a leſs heat is required. If indeed, much *phoſphorus* was to be made, this practice would be baſe and excellent; but Macquer aſſirms, that the method above deſcribed of Mr. Beaume is very convenient when a large quantity of *phoſphorus* is not wanted, and that he has never ſeen it fail.

Phoſphorus does not paſs pure in this diſtillation, but is blackened by ſoot or coal, which it carries along with it: it may be eaſily purified and rendered white and fine by a ſecond diſtillation or rectification. This rectification is made in a ſmall glaſs retort, to which is adjuſted a ſmall receiver half full of water. A very gentle heat is ſufficient, becauſe *phoſphorus* once formed is very volatile: and as the fuliginous matters with which it is ſoiled were raiſed merely by the violence of the heat, they remain at the bottom of the retort in this diſtillation, and the *phoſphorus* paſſes very pure.

The *phoſphorus* is then uſually divided into ſmall cylindrical rolls, for the convenience of uſing it. This is done by putting it in glaſs tubes immerſed in warm water. This very gentle heat is ſufficient to liquefy the *phoſphorus*, which is almoſt as fuſible as fuet. It takes the form of the glaſs tubes, from which it may be taken out when it is cold and hardened. That it may be more eaſily taken out of the tubes, theſe muſt be ſomewhat of the form of ſtraws of corn. All theſe operations ought to be made under water, to prevent the inflammation of the *phoſphorus*.

Phoſphorus is a kind of ſulphur compoſed of a peculiar acid united with phlogiſton. It is extremely fuſible, and has, like ſulphur, two kinds of inflammation; one very weak, emitting a flame not powerful enough to kindle other combuſtible matters, but ſufficient for the gradual conſumption and burning of its own phlogiſton; the other is vivid, brilliant, and ſtrong, accompanied with decrepitation, and capable of inſtantly kindling any combuſtible matter. *Phoſphorus* reſembles vitriolic ſulphur in this reſpect, that all its phlogiſton may be burnt, even with rapidity, without any decompoſition of its acid: but it differs from ſulphur in being much more combuſtible. A heat from twelve to fifteen degrees is ſufficient to decompoſe *phoſphorus*, and to make its phlogiſton burn, with a ſenſible light, eſpecially in open air; and, therefore, to prevent this decompoſition, it muſt be preſerved in water; though in water it will be partly decompoſed, and fill the containing bottle with luminous vapours; its ſurface loſing its ſemi-tranſparency, and the water becoming more and more acid.

Phoſphorus, heated by fire or friction, violently inflames, burns fiercely, and emits many vapours. It does not ſeem to be ſo ſtrongly diſpoſed to unite with metals as ſulphur. *Phoſphorus* is ſoluble in oils and inflammable liquors, and forms baſſams of *phoſphorus*; but in this ſtate of combination, it is more diſpoſed to decompoſe than when alone. The nature of the acid which enters into the compoſition of *phoſphorus* is not certainly known: Stahl and many others have ſuppoſed it to be the marine acid; and that nothing more was requiſite to produce it than to mix and combine properly marine acid with phlogiſton; but *M.* Margraaf, by many experiments found that the phoſphoric acid was different from that of common ſalt; and that it was contained in that ſingular kind of ſalt, which chemiſts call ſuſible ſalt, or native ſalt of urine. When the inflammable principle of *phoſphorus* burns, and is thus ſeparated from the acid, we obtain a diſengaged ſubſtance, which is at firſt dry, but quickly and powerfully attracts the moiſture of air, and is thus reduced to a liquor that has an acid taſte, that converts the blue colour of vegetables to a red, and that combines to the point of ſaturation with alkaline ſubſtances. This ſubſtance, being deprived of its moiſture by heat, and rendered red hot, may be thus converted into a ſolid and tranſparent matter, which has all the appearance of glaſs. Phoſphoric acid appears to be a very powerful ſolvent: it decompoſes nitre and common ſalt, uniting with their alkaline baſes, and when combined to the point of ſaturation with alkaline ſalts, forms neutral ſalts ſimilar to the ſuſible ſalt of urine. This acid diſſolves neither gold nor ſilver; acts in a ſmall degree on filings of copper, but eaſily diſſolves the calx of copper; entirely diſſolves iron; weakly corrodes tin and lead; changes the colour of mercury precipitated *per ſe*, from a red to a yellow and white, and by a long digeſtion to a black; and entirely diſſolves white arſenic and zinc.

With regard to the effects of phoſphoric acid on the ſolutions of metals by other acids, we may obſerve, that it produces no change in the ſolution of gold in aqua regia, but ſome time afterwards precipitates part of the gold in its metallic ſtate, and it affects the ſolution of ſilver nearly in the ſame manner: from the ſolution of mercury in nitrous acid, a copious white precipitate is formed by the phoſphoric acid, which is re-diſſolved by expoſure to the cold. A white precipitate is alſo obtained from a ſolution of lead in nitrous acid, by means of the phoſphoric acid. Such are the principal properties of this acid, enumerated by Margraaf, who found that it is not peculiar to animal urine, having been diſcovered in many vegetable matters, particularly farinaceous grains, when expoſed to great heat in cloſe veſſels. To which we may add, that M. Schloſſer perceived no farther effect than a diminution of weight by keeping it in hot and cold ſpirit of wine; that ſpirit of turpentine did not affect it; that no effervеſcence was perceivable by diſſolving it in water and adding fixed alkali; that an ounce of water was capable of diſſolving one hundred and eight grains of ſalt, when the thermometer was at 56°; that this ſalt cryſtallizes in ſmall parallel and equal priſms, with four oblong equal ſides, and two truncated extremities; that, when diſſolved, it did not affect gold, tin, lead, mercury or ſilver; that filings of ſteel rendered the ſolution whitiſh, but clear; that copper was ſlightly corroded, biſmuth not touched, zinc ſlowly diſſolved by means of heat; that it precipitated ſilver from aqua fortis, in form of a black powder, and mercury from aqua fortis in a white maſs, and copper, iron and tin, from aqua fortis; that it did not affect lead diſſolved in aqua fortis; that it precipitated biſmuth and antimony in form of a white powder; and that zinc diſſolved in aqua fortis remained undiſturbed. Dr. Prieſtley obſerves, that this acid may be eaſily procured from ſolid *phoſphorus* by expoſing it to the open air in the mouth of a phial, paſſing into a phial which receives the acid, as the *phoſphorus* gradually waſtes by this kind of accenſion; but it muſt be ſet in a place, neither very cold nor very warm. If it ſmokes, and is in danger of taking *fire*, it may be preſerved by plunging it inſtantly in water. This phoſphoric acid, he ſays, is ſoon ſaturated with nitrous vapour, and aſſumes a deep indigo

indigo blue colour; it yields no air by heat, even with substances containing phlogiston, except that in the solution of iron, which it readily dissolves, and by mixing it with minium, it yielded a strong inflammable air.

Dr. Ingenhousz observes that the phosphoric acid, when hot, dissolves glass. M. Scheele has lately discovered a curious and easy method of procuring the phosphoric acid from bones, by means of the oil of vitriol: the process for this purpose has been since stated and explained, in the various circumstances attending it, by other chemists.

Messrs. de Morveau, Maret, and Durande, in the Elemens de Chymie, &c. lately published at Dijon, used twelve pounds of bone calcined to whiteness, finely powdered and sifted, and added to them a sufficient quantity of the common or strong oil of vitriol, till an effervescence no longer appeared. They then added a little more of the acid, and afterwards a little water, in order to promote the action of the acid upon the earth.

An anonymous writer observes, that the effervescence appears to have no necessary connection with the expulsion of the phosphoric acid from the bones, as it depends only on the expulsion of a certain quantity of fixed air contained in them: and, as the quantity of oil of vitriol is not stated by other writers, he adds, from his own experience, that in a process of this kind, ten ounces in weight of the strongest oil of vitriol were added to eight ounces of burnt hartshorn, or the CCC. of the shops. The matter thus obtained is boiled for a long time, with the addition of a large quantity of water, and afterwards filtered; and the matter remaining in the filter repeatedly edulcorated with hot water. The whole quantity is then set to evaporate, first in earthen vessels, and afterwards in capsules of glass or china ware. To expel the vitriolic acid from the liquor thus concentrated, M. Scheele directs that it should be distilled to dryness in a glass retort placed in a reverberatory furnace. The other authors effect this expulsion with less trouble in the glass capsules; and then put the dry matter into a crucible, where it was kept in fusion till it ceased to yield sulphureous vapours. It was then poured out of the crucible in a vitreous state.

To procure the phosphoric acid in a state of greater purity, or more free from selenite, or earth, it is proper first to convert it into *phosphorus*. For this purpose, the authors of the Elemens Chymie, &c. just cited, having reduced the whole of the vitreous substance into powder, and mixed it with one-third of its weight of powdered charcoal, distilled the mixture in an earthen retort. From the quantity of calcined bones above mentioned, they obtained six ounces and seven drachms of excellent *phosphorus*. From this, the acid may easily be afterwards obtained in the purest state, by the usual method of accension, &c. It is observed that the phosphoric acid may be procured in still greater quantity from egg-shells; and that it has even been found in the mineral kingdom, and obtained from certain white lead ores. Monthly Review, vol. lxvi. p. 135, &c.

Dr. Priestley has made many experiments with *phosphorus*, in different kinds of air; and has found, that it smoked and gave light in the acid air, just as it would have done in common air confined, without being sensibly wasted for twelve hours, and with a very inconsiderable diminution of the bulk of the air; in alkaline air it gave no light and made no lasting change in its dimensions; in nitrous air, it gave no light, nor did it lessen its power of diminishing common air, and the *phosphorus* remained unchanged; and after having remained a day and two nights in vitriolic acid air, it produced no sensible effect, and gave no light.

Dr. Fordyce has suggested the following easy method of reducing *phosphorus* to powder: take *phosphorus* of urine two drachms; put it into a four-ounce phial; pour upon it three ounces of water; heat it gently by immersion in warm water, till the *phosphorus* melts; shut the phial with a cork; take it out of the water, and shake it briskly till it be cold; and the *phosphorus* will be found in powder. A receiver may be lined with this powder by adding a very small quantity of water to it, and then making the powder to adhere to its internal surface, by gently inclining and turning the receiver round. Chem. Dict. art. *Phosphorus*, and Priestley's Experiments and Observations on Air, &c. Phil. Trans. vol. lxi. part 2. p. 504, &c.

PHOSPHORUS, *properties of solid*. 1. With this *phosphorus* one may write on paper, as with a pencil, and the letters will appear like flame in the dark; yet, in the light, nothing will appear, but a dim smoke.

If the letters written with this *phosphorus* are warmed by the fire, they presently become dark lines, which continue upon the paper like ink.

2. A little piece, rubbed between two papers, takes fire instantaneously, and, if care be not taken in the management of it, there is danger of burning the fingers, the *phosphorus* being exceedingly inflammable.

3. Its burning is very vehement, and penetrates deeper into the flesh than common fire; and it is very difficult to be extinguished.

Dr. Shire, in order to determine whether air contains the pabulum of flame, as some have supposed, placed a large piece of *phosphorus* in a receiver; but upon exhausting it, he found that it became more luminous, and that upon admitting the air, it returned to its former state. This property was also ascertained by several experiments of Mr. Hauksbee.

M. Cassini happening to press a piece in a cloth between his fingers, the cloth immediately took fire; he endeavoured to put it out with his foot; but his shoe caught the flame, and he was obliged to extinguish it with a brass ruler, which cast forth rays in the dark for two months after.

The solid *phosphorus* ceases to shine and never spoils, provided it be kept in a phial full of water; but if any part of it emerge, it will shine, though the glass be hermetically sealed; and it will continue shining in a large glass without water for several days, with very little diminution of its light or weight; and even when immersed in water, it will sometimes make very bright and vigorous ebullitions in the air: that, in form of an unguent, does not keep so well; and the liquid *phosphorus* worst of all.

The liquid *phosphorus* is best made by digesting, in boiling, a little bit, or some scrapings, of the solid kind, for two days, in oil or essence of cloves, oil of turpentine, or the like. After dissolution, the oil will be impregnated with it, that, upon opening the bottle, the matter will appear on a flame.

PHOSPHORUS, *experiments with liquid*. By washing the face, hands, or the like, with liquid *phosphorus*, Dr. Stare tells us they will be made to shine very considerably in the dark, and the lustre thereof will be communicated to adjacent objects, yet without any offence to the skin.

As soon as the candle is brought in, the shining disappears, and no change is perceivable.

This *phosphorus* emits frequent flashes like lightning, even when close stopped, especially in warm water. Hence Mr. Boyle takes occasion to draw a parallel between lightning and *phosphorus*. Phil. Trans. Abr. vol. iii. p. 348, &c. Hauksbee's Physico Mech. Exper. p. 122.

In some cases animal sweat, which is similar to urine, has been observed to be phosphoraceous, without any preparation. An influence of this kind is related of a person, who used to eat great quantities of salt, and who was a little subject to the gout, after sweating with violent exercise. Stripping himself in the dark, his shirt seemed to be on fire, and an urinous smell was perceived, similar to that which issues from cabbage much salted and strongly fermenting. Act. Curiosorum, vol. v. p. 334.

PHOSPHORUS, *Bolognian*, or *Bononian*. The second kind of artificial *phosphorus* is a preparation of a stone called the *Bononian* stone, from *Bologna*, a city in Italy, near which it is found.

The first who undertook to make this stone luminous, was a chemist of that city, called Vicenzo Cascrorolo. Peterus, Licetus, &c. have described the process; but mistakenly. M. Homberg, who made a journey to Italy, expressly to learn the preparation, first communicated the same to M. Lemery, who published it in the seventh edition of his chemistry. See BOWONIAN *stone*, and LAPIS *Bononiensis*. Under those articles, the reader will find some account of the discovery of this stone, and of the method of preparing it. We shall here subjoin some farther particulars on this subject, chiefly extracted from the dissertations of M. Margraaf. The Bolognian stone, he says, is soft, friable, heavy, crystallized, and incapable of effervescing with acids, before it has been calcined in contact with fuel, and with a free access of air. These qualities have induced him to class it among the heavy fusible spars, which, by a preparation similar to that for the Bolognian stone, are rendered phosphoric. After analyzing these substances, he concludes that all contain a vitriolic acid, united to an alkaline or calcareous earth. In order to render these stones phosphoric, such of them ought to be chosen as are the clearest, but crystallized, most friable, most heavy, which exfoliate when broken, and which contain no heterogeneous parts. They are to be made red-hot in a crucible, and reduced to a very fine powder in a glass mortar, or upon a porphyry, and not in a copper mortar, which will obstruct the success of the operation. The powder thus obtained is to be formed into a paste with gum tragacanth, and divided into cakes as thin as a knife. These are to be dried by a gradual heat. An ordinary reverberatory furnace is to be filled to three quarters of its height with charcoal, and the fire to be kindled; upon

this charcoal the flat furfaces of the cakes are to reft; and more charcoal is to be placed above them, fo as to fill the furnace, which is then to be covered with its dome, the tube remaining open: all the coal is to be conſumed, and the furnace left to cool. The cakes are then calcined, and are to be cleanſed from the aſhes by blowing upon them with bellows. He further obſerves, that after this calcination, through the coals, if the ſtones be expoſed to a ſtronger calcination during a full half hour under a muffle, their phoſphoric quality will be rendered ſtronger. Ac. Berlin, 1749, and 1750.

This *phoſphorus* has not any ſenſible heat, and only becomes luminous after being expoſed to the ſun, or the day-light; in which ſtate it reſembles a burning coal, and preſerves its light five or ſix minutes in the dark, eſpecially if the perſon obſerving it has been ſome time in the dark, or has ſhut his eyes, that the pupils may be ſufficiently expanded; during which time, the light gradually diminiſhes; and, to recover the ſhining, it muſt be expoſed afreſh to the light.

PHOSPHORUS, *the hermetic*, or PHOSPHORUS *Baldwini*, which makes the third kind, and properly belonging to the ſame claſs with the former, is a preparation of Engliſh chalk, with aqua fortis, or ſpirit of nitre, by the fire.

This makes a body conſiderably ſofter than the Bolognian ſtone; but it has all the qualities thereof. It has its name from its inventor Baldwin, a German chemiſt, called *Hermes*, in the ſociety of the Naturæ Curioſorum; whence its other name *Hermetic*. It was diſcovered a little before the year 1677.

This *phoſphorus* of Baldwin is exactly ſimilar to thoſe made with Bolognian ſtone and phoſphoric ſpars, differing only in the kind of acid which it contains. It is evidently a nitre with a calcareous baſis, and in calcination acquires its phlogiſton from the nitrous acid, the chalk alſo containing ſome of this inflammable principle. It is obſerved, however, that this is not ſo good a *phoſphorus* as the Bolognian; it is not ſo luminous, it does not retain the light ſo long, it ſoon loſes its virtue, and never recovers it again. Acad. Par. 1692, p. 271.

The proceſs for making this *phoſphorus*, though Baldwin gave no directions for it, nor ſo much as mentioned the materials, was communicated to the Royal Society, in 1679, by Dr. Slare, and publiſhed by Grew, in his Muſ. Reg. Soc. p. 353; and is as follows: take good firm chalk, ignite it in a crucible, and then powder it; put into a pint or half a pint of ſtrong ſpirit of nitre, *reſolution*, as much of the powdered chalk as will ſerve well to ſaturate it, i. e. till it becomes ſweetiſh, and makes no effervescence upon the injection of the chalk. Then diſſolve this liquor with fair water, filter it through a paper, and ſo evaporate it in a large glaſs, or glazed veſſel, or good Italian crucible to a dry ſalt. The preparation may be performed in four hours.

To this claſs we may alſo refer ſome other *phoſphori*, enumerated in the ſequel of this article. As the

PHOSPHORUS, *ammoniacal*, compoſed of ſal ammoniac and lime, which Mr. Homberg firſt diſcovered.

The method of preparing it is this: take one part of ſal ammoniac in powder, and two parts of lime extinguiſhed by lying in the air: mix them exactly together, and fill a crucible with the mixture; ſet it in a ſmall melting heat. As ſoon as the crucible grows red hot, the matter in it will melt, and it muſt be ſtirred with an iron rod, leſt it ſwell over the edges of the crucible: as ſoon as the whole is melted, pour it into a copper baſon; it will appear of a greyiſh colour and vitrified, and if it be ſtruck upon with any hard body, there will be ſeen a fire all over the place where the blow was given. As this matter is brittle, however, and the ſame maſs will not ſerve often for the experiment, the beſt method is to dip iron rods in it while melting, and theſe will be covered with the matter, and will anſwer the purpoſe eaſily and often. Mem. Acad. Par. 1693.

This is a combination of quick-lime with the acid of ſal ammoniac, and receives its phlogiſton from the ſal ammoniac.

PHOSPHORUS, *antimonial*, is the name of a ſubſtance having the qualities of the *phoſphorus* diſcovered by Mr. Geoffroy in his experiments on antimony. This gentleman had prepared a ſoap from pot-aſhes, quick-lime, and oil, with which he made ſeveral experiments on antimony; among others he was deſirous, by means of this, to reduce ſome diaphoretic antimony, which he had before made from two parts of the regulus of antimony, and three parts of nitre; but, inſtead of the reduction which he was labouring after, his operation afforded him a much more ſingular phenomenon: the reſult of them being a *phoſphorus*, which he had never thought of; a matter which, after having remained perfectly quiet while cloſe ſtopped down, took fire as ſoon as ever it was expoſed to the air; and that with a violent detonation, and darting every way a ſhower of fire.

It is eaſy to ſee, that there are in the preparation all the requiſites for ſuch an effect; nitre, charcoal furniſhed by the burnt ſoap, and ſulphur both from the ſoap and from the regulus of antimony; and to all theſe, a fixt oil ſalt, either from the ſoap, or from ſome earthy parts of the antimony. It is eaſy to conceive, that all theſe ſubſtances, coming to a mixture together, ſhould be ready to catch fire and blaze, upon a proper application; but it is not leſs difficult to account for the effect's being produced merely by the air, after the whole had been for a long time in a ſtate of reſt.

The method of preparing this new ſpecies of *phoſphorus* is this: Mr. Geoffroy mixed two ounces of his ſoap with one ounce of this diaphoretic antimony; this mixture, being put by little and little into a red hot crucible, took fire, and ſwelled very much; after it had done flaming, the maſs ſubſided, and became a red or fire-coloured ſubſtance, of an even ſurface, but ſtill throwing up a vaſt quantity of bluiſh-green luminous vapours: and all this regularly happened on every freſh throwing in of the matter, without the leaſt variety; when the whole quantity was thrown in, and had ceaſed to give any flame or luminous vapour, it remained in the crucible in the form of an inverted muſhroom, being hollow, very porous, and of a black colour. When the crucible was taken out of the fire, the edges of this ſubſtance were beaten down into the middle, and the whole covered with an ounce of freſh ſoap; when this laſt ſoap was burnt, and a ſmall bluiſh flame appeared upon the ſurface of the maſs, the crucible was covered with a lid, and a large quantity of charcoal laid upon it, and the fire blowed up with bellows, by a hundred blaſts of the bellows, or thereabouts; but, notwithſtanding the fierceneſs of the fire, there was no fluid ſcoria formed, but the whole maſs remained ſpungy and porous; the fire was then ſuffered to go out, and the crucible placed in a corner of the elaboratory at reſt for five hours. In the evening, when the crucible was perfectly cold, Mr. Geoffroy went to examine the matter, and a ſervant went to uncover the maſs, by removing its ſurface with an iron inſtrument; but the moment the air was admitted, the whole maſs took fire, burning with a very conſiderable muſſle, and darting its flames every way to a great diſtance.

Mr. Geoffroy repeated the proceſs ſeveral times, and always with the ſame ſucceſs, whether he uſed his own diaphoretic antimony, or that made in the common manner. The great caution to inſure the ſucceſs, ſeems to be taking care of not carrying the fire too far before the addition of the laſt quantity of ſoap. Mem. Acad. Scien. Par. 1736.

PHOSPHORUS *of the Berneſtone*, is a name given to ſtone, (which, when heated, becomes a ſort of *phoſphorus*) from Berne, in Switzerland, the place where it is found.

This ſubſtance was ſent to the members of the Royal Academy at Paris, by M. Bourgnon, and referred by them to the examination of M. Du Fay, whoſe account of it is publiſhed in Mem. Acad. Paris. 1724.

The *Berne-ſtone* is of a moderate hardneſs, conſiderably pellucid, and uſually colourleſs, or whitiſh, though ſometimes with a tinge of green, yellow, or ſome other colours: it is compoſed of numbers of plates, or flakes, laid over one another, in the manner of the iſland cryſtal; and therefore, like that body, is plainly a ſpar. It breaks into ſeveral faces, and has different angles, but of a ſomewhat determinate meaſure, the acute ones being of ſixty degrees, and the obtuſe ones of one hundred and twenty.

This ſtone, when heated at one of its angles with the flame of a lamp or candle, ſplits by means of the flame's inſinuating itſelf into the interſtices of the plates that are leſs firmly united; and theſe ſeparate, and ſome fragments uſually fly off with conſiderable violence. One of theſe pieces, carried into an obſcure place, appears ſurrounded with a blue flame, which laſts about a minute. And it is to be obſerved, that theſe pieces which fly off have all the ſhape of an irregular pyramid, with an uneven baſe. If this ſtone be put into a crucible, and ſurrounded with coals, it becomes a very beautiful *phoſphorus*. The whole bottom of the crucible is ſeen, even though it be in broad day-light, ſhining with a bright and beautiful bluiſh white; and if it be carried into a dark place, the light is ſeen much more beautifully. If, after it is cold, it be again heated in a crucible, in the ſame manner it ſhews the ſame bright appearance. After this, if it be tried a third time, it does not ſhine at all. According to all theſe phenomena, the effects of fire upon this ſtone ſeem to depend on a ſulphur contained in it, probably of the ſame nature with that which enters the compoſition of the metals. This may, by means of a heat, ſuch as that

given by the candle or in the crucible, disengage itself so far from the body of the ſtone as to take fire; and when it has burnt ſo long as to conſume itſelf, the luminous property of the ſtone ſeems to ceaſe.

The coloured gems are cryſtals of a peculiar kind, tinged with the ſulphur or PHLOGISTON of metals: this ſulphur gives them their colour, and conſequently it ought to give them the properties of *the Bononian ſtone*, if it were not too fixed to be diſſipated in the ſame eaſy manner, and to take fire in the diſſipation. And it appears, on trial, that the baſtard emeralds of Auvergne and other places, the matrix of the amethyſt, the fragments of ſome of the accidental jaſpers, the hyacinths, and ſome ſort of rubies, are all *phoſphoruſes* of the nature of the *Bononian ſtone*, but with different degrees of brightneſs. The mother of the emerald, the yellow jaſper, the water ſapphire, the malachite, the opal, and the garnet, have none of them any of this property.

Since the ſame ſulphurs which take fire in the *Bononian ſtone* are what give colour to theſe other ſtones, it ſhould ſeem, that thoſe which are not of this *phoſphorus* kind, nor give a light after being heated, ſhould not loſe their colours in the fire; and this is found to be true in the garnet, which does not loſe any part of its colour, nor is it at all luminous; whereas the hyacinth, and ſome of the jaſpers and other ſtones, which loſe a part of their colour, not the whole, in the fire, become alſo in part luminous, or more ſo, in degree, according to the quantity of colour which they loſe. This however, is no certain rule, ſince the mother of the emerald, the topaz, and ſome other ſtones, loſe all their colours, and yet are not at all luminous. The reaſon of this ſeems to be, that the ſulphurs are driven out of theſe ſtones ſo ſlowly, and in ſuch minute quantities, that they are not at any time collected into body enough to be capable of flame. There is nothing to be objected as to the *Bononian ſtone* ſhining: though they are uſually white, they may poſſeſs no ſmaller portion of ſulphurs than the coloured ſtones: only in theſe the ſulphur may be colourleſs, or white in themſelves. It may be poſſible alſo that the ſulphurs in a ſtone of this kind, may be diſperſed in ſuch ſmall molecules, as not to form a body ſufficient to give any colour; but, when collected, in order to be driven off in the fire, they may then be ſufficient in quantity to give a blue tinge to the flame.

The iſland cryſtal, which is alſo a ſpecies of ſpar, and which greatly reſembles this *Bononian ſtone* in many particulars, flies to pieces alſo in the ſame manner, on being heated; and when carried into the dark, this alſo gives ſome ſparks of light, but they are few in number, and looſely ſcattered over the ſurface: when this ſtone is burnt a little in the crucible, there is ſome ſmall appearance of flame, with a ſmell of ſulphur, and the matter in the bottom of the crucible is found ſhattered to pieces; but all the pieces are regular parallelopipeds, as was the original maſs.

It is to be obſerved, that the *Bononian*, and others of the ſame kind, which only ſhine in the dark, and that only for a few minutes, when firſt taken out of the fire, are, properly ſpeaking, endued with no other luminous quality than that of a burning coal; but their light, having been generally conſidered, and requiring darkneſs to ſhew it, has obtained for them the ſpecious title of *phoſphori*.

PHOSPHORUS, *Canton's*, is an artificial *phoſphorus*, the method of preparing which was diſcovered by the late ingenious Mr. Canton, and publiſhed in the Phil. Tranſ. for 1768, vol. lviii. p. 337, &c.

This is much ſuperior to any ſingle natural ſubſtance, and has the advantage of being very eaſily and cheaply prepared. The proceſs is as follows: calcine ſome common oyſter-ſhells, by keeping them in a good coal fire for half an hour; let the pureſt part of the calx be pulverized, and ſifted; mix with three parts of this powder one part of the flowers of ſulphur; let this mixture be rammed into a crucible of about an inch and a half in depth, till it be almoſt full; and let it be placed in the middle of the fire, where it muſt be kept red hot for one hour at leaſt, and then ſet by to cool: when cold, turn it out of the crucible, and cutting, or breaking it to pieces, ſcrape off, upon trial, the brighteſt parts; which, if good *phoſphorus*, will be a white powder, and may be preſerved by keeping it in a dry phial with a ground ſtopple. The quantity of light which a little of this *phoſphorus* gives, when firſt brought into a dark room, after it has been expoſed for a few ſeconds, on the outſide of a window to the common light of the day, is ſufficient to diſcover the time by a watch, if the eyes have been ſtout, or in the dark, for two or three minutes before. By this *phoſphorus* celeſtial objects may be very well repreſented; as Saturn and his ring, the phaſes of the moon, &c. if the figures of them, made of wood, be wetted with the white of an egg, and then covered with the *phoſphorus*. And theſe figures appear to be as ſtrongly illuminated in the night, by the flaſh from a near diſcharge of an electrified bottle, as by the light of the day. This *phoſphorus* receives no injury from being expoſed to the direct rays of the ſun, which is the caſe with ſome of the more delicate kinds, as Beccarius has remarked, and Lemery impoſed with all. However, it cannot be expoſed to moiſture without loſing its property of imbibing and emitting light, and alſo its whiteneſs. Mr. Canton found, that it was more affected by mixture with ſpirit of wine than with æther. It had been long known, that heat promotes the expulſion of the light which has been formerly imbibed by theſe *phoſphori*: Mentzel, who wrote ſoon after the diſcovery of Baldwin's *phoſphorus*, aſſerted, that it had the property of becoming luminous by heat only; the ſame fact was obſerved by M. Du Fay; but the principle on which it depended was diſcovered by Beccarius, M. Margraaf, and Mr. Canton, independently of one another. Beccarius was firſt of opinion with Mentzel, that the light was produced by heat; but finding by repeated trials, that, without previous expoſing to the light, heat had no effect, he relinquiſhed that opinion. Mr. Margraaf fell at firſt into the ſame miſtake with Beccarius; but he afterwards obſerved, that the *phoſphorus* would not ſhine by being placed upon a hot furnace, unleſs it had been expoſed to the light two or three days before. Upon the whole, he concludes, that the light is held in this ſubſtance by attraction, and afterwards expelled by heat. Mr. Canton alſo, without any knowledge of the obſervations of Beccarius and Margraaf, found, by a variety of experiments, that when his *phoſphorus* had imbibed light, and had emitted all that it could in the common ſtate of the atmoſphere, it would emit more upon the application of heat, but that a continuance of the ſame degree of heat would only make it luminous for a certain time. Whence he infers, that there is a ſtrong attraction between light and the particles of natural bodies, and that the ſtrong vibrations into which heat throws them compels them, as it were, to quit their hold of each other; and the light which this *phoſphorus* gives, by being heated to a certain degree, appears to be cauſed by its throwing off adventitious particles, and not by any of its own; ſince its light will decreaſe, and be entirely gone, before the *phoſphorus* be hot enough to ſhine of itſelf, or to emit particles of light from its own body. Lemery and Muſchenbroeck have obſerved, that the Bononian *phoſphorus* imbibes leſs light when hot than cold, becauſe it appears leſs bright when carried into a dark room; but this circumſtance is accounted for by Mr. Canton, by its parting with its light ſooner when hot than when cold, and, therefore, parting with more in the time of the conveyance from one place to another: and this, he alſo ſays, ſeems to be the cauſe why the Bononian *phoſphorus* never appears ſo bright after it has been illuminated, and, conſequently, in ſome meaſure heated, by the direct rays of the ſun, as after it has been only expoſed in the ſhaded open air, to the common light of the day. However, there is reaſon to imagine, that the ſame degree of heat, which diſpoſes the *phoſphorus* to throw off the light after it has been imbibed, muſt likewiſe render it indiſpoſed to receive it. For an account of the reſult of Mr. Canton's experiments on this ſubſtance in favour of the materiality of light, ſee LIGHT.

PHOSPHORUS *fecalis*, a very fine kind of *phoſphorus*, exhibiting many wonderful phenomena, and prepared from human dung mixed with alum.

Mr. Homberg, who was the inventor of it, gives the method of preparing it in the following manner: take four ounces of human dung newly made, mix it with the ſame quantity of reſined alum groſly powdered; put the mixture into a ſmall iron ladle, capable of holding about a pint; ſet it over the fire in a chimney, and it will melt together, and become as fluid as water; let it boil groſly over a ſmall fire, continually ſtirring it with an iron ſpatula till it is dry; it will then be difficult to ſtir, but it muſt be kept ſtirring about, and all the lumps it runs into muſt be broken, and what adheres to the ſides of the ladle ſtirred in and blended with the reſt; this muſt be continued till it is perfectly dry, and the ladle muſt be now and then taken from the fire, and the matter ſtirred about in it, that it may not grow red-hot. When the whole is thus perfectly dried, it will ſtill be in little lumps, and when cold it muſt be rubbed to powder in a metal mortar; it muſt then be put into the ladle, and ſet over the fire again, in will then become a little moiſt again, and run into clods and grumes, but it muſt be again ſtirred till dry; when cold it is to be powdered again, and a third time put into the ladle; and when perfectly dried this time, it is to be laid by in a paper in a dry place; thus is the firſt or preparatory operation finiſhed.

Take two or three drams of this powder, put it into a ſmall matraſs, capable of holding an ounce and half of water, and which has a neck ſix or ſeven inches long; put

put a paper ſtopper lightly into the neck of the matraſs; then take a ſmall crucible of three or four fingers breadth high, put two or three ſpoonfuls of ſand into it, then ſet the bottom of the matraſs on the ſand, and take care that no part of it touches the ſides of the crucible; fill up the reſt of the crucible with ſand, and let the whole body of the matraſs be covered with it; then ſet the crucible in one of the common little earthen furnaces, and make a charcoal fire about it; for the firſt half hour let the coals only reach up to the middle of the crucible, but afterwards lay them up to the rim of it; continue this fire about half an hour, or till the powder within the matraſs is red-hot; then pile up more charcoal above the rim of the crucible, and continue this fire an hour, after which let the whole cool. There will riſe a large quantity of fumes during the operation, and they will often throw out the ſtopper of the matraſs; but this muſt be replaced, and the fire a little abated in that caſe: when theſe fumes ceaſe, the fire may be raiſed without hurting the proceſs, when the crucible is ſo cool that it may be taken out of the furnace without burning the hands. This is to be done, and the matraſs is to be half raiſed out of the ſand to make it bear the cold by degrees, and its mouth muſt then be ſtopped cloſely with a cork, inſtead of its paper ſtopper. If, on ſhaking the matraſs about, the matter falls into powder, it is a proof that the operation has been well performed; but, if it hangs together in form of a cake, it is a ſign that the matter was not well roaſted in the ladle before the putting it into the matraſs.

When the operation has been well performed, and the matter is in powder in the matraſs, pour out a ſmall quantity of it on a piece of paper, and immediately ſtop the matraſs again: the powder upon the paper will immediately fume and take fire, burning the paper, and any other combuſtible matter that is in the way. If there has been too much of the powder poured out of the matraſs, it muſt not be returned in again; for though that ſhould be done before it begins to ſmoak, yet it will certainly ſet fire to all that is in the matraſs; from this it may be eaſily ſeen alſo, that the matter cannot be emptied out of the matraſs into a phial, but muſt always be in the veſſel in which the calcination was made.

If too much alum be uſed, the powder will not take fire at all: it will be of different colours, according to the veſſel the firſt calcination was made in, and according to the degree of fire that was uſed; hence it is ſometimes black, ſometimes brown, ſometimes red, green, yellow, or white.

It takes fire equally well in the day-time and in the night, and that without the mixture of any other ſubſtance, or without the leaſt rubbing, or any other circumſtance beſide the mere expoſure to the air. In this it differs from all the other known artificial *phoſphori*; for that of urine requires a ſmall degree of heat, in order to its burning; the ſolargodine *phoſphorus* requires a conſiderable degree; the Bononian ſtone does not ſhine, except after having been expoſed to the day light; and all the others require violent rubbing, or a ſmart blow, to produce their light.

It is be deſired to keep this powder good for any time, it muſt be put in a dry place where there is not too much heat; the mouth of the matraſs muſt be kept cloſe ſtopped, and its body covered with paper; and the place where it ſtands muſt not be in too ſtrong a light; for the open day-light has been often known to weaken its power, and, in fine, wholly to ſpoil it through the glaſs. Mem. Acad. Par. 1711. See PYROPHORUS.

PHOSPHORUS, *ſulphurating*. See PULGERATING.

PHOSPHORUS *metallorum*, a name given by ſome chemiſts to a preparation of a certain mineral ſpar, which is found in the mines of Saxony, and other places, where there is copper. The ſpar to be uſed on this occaſion is that kind which is tinged green, and from its, in ſome degree, reſembling the colour of the emerald, is called by ſome *gemmæ viridis*, and by others *lapis smaragdi mineralis*. This is to be powdered very fine, and this powder is to be laid on a flat plate of copper, iron, or any other metal: this plate is then to be ſet over ſome lighted charcoal, and the whole placed in a dark place. The ſpar will receive its neceſſary degree of heat for ſhining long before the metal will, and, conſequently, as ſoon as it begins to ſhine, the fire is not to be made any briſker. While the plate of metal is held in this degree of heat, and does not appear at all red, the powder upon it will ſhine like a lighted coal, and will continue ſo for ſome time. If it be removed away, and ſuffered to cool, it will be fit to repeat the experiment a ſecond time with, but its light will not be ſo ſtrong as before. Phil. Tranſ. N° 246. p. 365.

PHOSPHORUS *of ſulphur*, the name given by the French academicians to a new-diſcovered ſpecies of *phoſphorus*, which readily takes fire on being expoſed to the open air. See PYROPHORUS.

The invention was Mr. Le Fevre's, and the proceſs is this: the ingredients are two drams of common *ſulphur*, half an ounce of ſteel filings, ten grains of colophony, and ſix drams of common water. Theſe things being all weighed and ſet apart, powder about half a dram of the *ſulphur* in a ſmall mortar, then add the colophony, and afterwards the remainder of the *ſulphur*. When this is all reduced to a fine powder, put in the filings of ſteel, and rub the whole together till it is ſo thoroughly mixed, that the ſteel does not appear, but the colour of the whole looks every where uniform and regular; then add about twenty drops of the water; and after beating the whole together add as much more, and continue to do ſo till the maſs is of the conſiſtance of a paſte, but not too moiſt. Put this paſte into a ſmall matraſs that will contain about three ounces, and pour on it more of the water till it ſwim above the ſurface of the paſte near a quarter of an inch. The matter of the paſte will then break, and appear in form of a granulated powder under the water; put the matraſs on a ſand furnace, but give it no greater heat than that the hand can bear to lie upon the matraſs. When it begins to heat, the mixture will ferment and ſwell, and become black; it is then to be ſtirred with an iron rod, and a little more water muſt be added every quarter of an hour, till the whole is uſed. The matter will then be very black and liquid; and it is to be then taken from the fire, and ſet by for the whole night. This is the firſt and moſt eſſential part of the operation, and in this great care is to be taken that the fire be not too violent; for if the *ſulphur* be burnt, the operation will be ſpoiled, and the matter would ferment ſo high as to run over at the mouth of the veſſel.

To finiſh the operation, a little water muſt be added to the matter, ſo as to ſwim over it, and the veſſel muſt be again ſet in the ſand, and a ſtronger fire given than before; this is known to be ſtrong enough when there is any humid vapour obſerved to ariſe out of the mouth of the veſſel. This fire is to be continued about two hours, that the greater part of the humidity may be evaporated; which is known by the iron rod finding ſome reſiſtance when put into the veſſel, and the matter it brings up being granulated and ſolid, or no longer moiſt, it muſt then be immediately taken from the fire, and the whole is then finiſhed. It is neceſſary to be very exact in this laſt and critical minute; for a very little longer handling on the fire will burn the *ſulphur*, and render all the former care of no effect. The black matter remaining in the matraſs is to be taken out, and the ſides ſcraped clean with an iron rod; any piece of this that happens to fall upon a paper takes fire in a very little time, and burns away like the other *phoſphorus*. The proceſs is a very nice one, but, by obſerving all the rules here laid down, ſeveral perſons have ſucceeded in making the *phoſphorus* to perfection: the whole intent of the operation ſeems to be to join together the minute particles of ſteel and *ſulphur*; which when thus joined cannot fail to be very inflammable, and to take fire on receiving the ſmalleſt humidity from the air to make them ferment.

It cannot but be obſerved, that this *phoſphorus* is founded on Lemery's experiments of ſteel and *ſulphur* taking fire together; but this is a much more nice and accurate operation, and a fine improvement on the original plan, which was only by mixing large quantities of ſteel-filings and *ſulphur* together into a paſte with water, and burying this in the earth to make it take fire of itſelf, and thus repreſent the natural phenomena of volcanoes, thunder, lightning, &c. Mem. Acad. Par. 1728.

Phoſphorus may be kindled by the effluvia of electricity. See Phil. Tranſ. N° 475. ſect. 14.

PHOSPHORUS, *rationale of the effects of*. It may be obſerved, that in moſt of the natural *phoſphori*, there is a briſk attrition or friction concerned; which we may ſuppoſe either to give the minute parts of the ſubſtance the proper motion and agitation neceſſary to convert them into fire, if fire be ſo producible (as Hooke, Boyle, Newton, and the generality of the Engliſh philoſophers, have ſuppoſed that it is), or elſe to expel and emit the particles of fire naturally contained in them.

In the factitious ſorts, we may note, that a long proceſs by fire is uſually required, wherein the matter undergoes divers cochions, torrefactions, calcinations, diſtillations, &c. in the courſe wherein a conſiderable quantity of fire muſt neceſſarily be imbibed, and may poſſibly be retained therein.

In that, e. gr. prepared of the fecal matter, M. Homberg obſerves, that the aqueous part of the ſubſtance muſt neceſſarily have all been evaporated, with the greateſt part of the oil, and volatile ſalt, leaving pores or vacuities in the places they poſſeſſed; ſo that what remains is a ſpongeous plexus of earth, and fixed ſalt, having nothing in its locuſts, or cavities, but ſome of the matter of the fire, which has been ſtopped and detained therein, much as in quick-lime.

This being supposed, we know, that the fixed salt, which is here pretty copious, will readily absorb the moisture of the contiguous air; and that the sudden introduction of such moisture into the pores of the powder, must produce a friction, which may excite a small degree of heat; and this joined with what fire was there already laid up, may make a heat sufficient to give fire to the small remains of oils too closely connected with the salt to have been carried off by the calcined fire; so that we have here every thing necessary to heat and light.

What confirms this doctrine is, that if the powder be kept in a vessel not sufficiently close, the air, insinuating by degrees, moistens and saturates it, but that so slowly, as not to produce friction enough to set it on fire; so that it is spoiled, and disabled from taking fire ever after: much as is the case in quick-lime, which, after it has lain some time in the air, ceases to grow hot, even by the affusion of water.

The reason why quick-lime, which contains a great quantity of particles of fire, as well as our powder, does not conceive heat by the access of the air, or the ingress of its moisture into the pores thereof, but that water must be thrown thereon, is, that the quick-lime, being more thoroughly calcined, retains too little fixed salt to imbibe the moisture readily and copiously enough to excite the necessary friction.

And the reason why quick-lime does not produce a flame, as the powder does, even when water is cast on it, is, that it did not retain enough of the oily matter to afford flame; for, if oil were mixed with it, a flame would readily ensue. Mem. de l'Acad. ann. 1711. See PYROPHORUS.

If we suppose, with Mr. du Fay, that all calcareous stones are capable of being rendered luminous, without the concurrence of an acid, we may then suspect that light is capable of adhering more to some bodies than to others, and that calcination gives to calcareous stones the property of retaining a greater quantity of light, and during a longer time, than other bodies can. This, however, as Mr. Macquer observes, is a vague conjecture, and not much supported by facts. But if we adopt M. Margraaf's opinion, which is more conformable to the result of experiments, that these stones cannot be rendered luminous without the concurrence of an acid, and the acid only contributes to give them, in a considerable degree, this property, we must conclude that acids have a principal share in its production. M. Macquer reasons on this general principle in the following manner: we know that acids in general, particularly the vitriolic and nitrous, have a strong affinity with PHLOGISTON; and that when they are united with this principle, they form compounds possessed of the properties of sulphur, or of *phosphorus*. It is also certain, that sulphur, *phosphorus*, and probably other compounds of acid and phlogiston, have two methods of burning; one, vivid and strong, in which their phlogiston forms a very sensible flame, and produces not only light, but heat sufficient to kindle combustible bodies; the other slow and weak, capable only of producing a light much less vivid, without any sensible heat, or with a heat too small to kindle the most combustible bodies. Hence, may we not with probability believe, that the acid contained in stones rendered *phosphoric* by calcination combines with the phlogiston of the coals, forming with it a sulphureous compound; and that the phlogiston of this kind of sulphur or *phosphorus* adhering but weakly to the acid, or exciting there perhaps only superabundantly, is very easily combustible; so that the mere action of the heat and light of the open air is sufficient to inflame it, but not so strongly as to produce heat and a total dissipation of the phlogiston, but to slowly and weakly, that only a faint light, observable in the dark, is produced? The English translator of the Chemical Dictionary adds, that the principal cause of the slow combustion which produces *phosphoric* light, seems to be, that the union between the acid and the phlogiston of *phosphoric* substances is weakened by the presence of some earth, to which the acid has also a disposition to unite; and that the phlogiston is thereby gradually disengaged, especially when it is in contact with air, to which it is at all times strongly disposed to unite, as we may perceive from the necessary concurrence of that fluid to maintain ordinary combustion, which is only a more rapid and copious disengagement of phlogiston from the burning substances. See Chem. Dict. art. *Phosphoric stones*, Eng. edit. and note z.

John Baptist Beccaria has shewn, Phil. Trans. vol. lxi. part i. art 25. that the *phosphorus* composed of sulphur and calcareous earth, imbibed the peculiar coloured rays to which it had been exposed. Thus, having exposed different *phosphoric* pieces to rays of the sun transmitted through green, yellow, and red crystals, he observed, that each of them, when afterwards viewed in the dark, exhibited that colour to which it had been exposed. This observation is decisive in favour of the opinion, that *phosphori* of this kind emits the same light that it receives, and no other; and that the light is not produced, but expelled by heat.

This experiment, which has often failed, for want of employing good glasses, or on account of the weakness of the solar rays, has been repeated by professor Allamand of Leyden; who says, that having exposed a prepared (probably by calcining it with some sulphureous substance) piece of the Bononian calcareous *phosphorus* to the coloured rays of the sun, after their being separated by one of his prisms, and looking to it in the dark, he found the *phosphorus* gave the colour of the separated rays to which it had been exposed.

PHOSPHUROUS, *aqueous*, a name given by Dr. Leigh, in his History of Lancashire, to a water found near Wigan in that county, which takes fire on holding a lighted candle to it. It is not properly the water, however, that takes fire in this case, but a flame which bursts out of the ground with it. The author also calls it a sulphurated water; but that very improperly, for it contains no sulphur, but only issues out with this bituminous vapour.

PHOSPHORUS, in *Astronomy*, is the morning star, or the planet VENUS, when she goes before the sun.

The same call it LUCIFER; the French *etoile de berger*, the Greeks *phosphoros*, from φως, *light*, and φερω, *I bear*, or *bring*.

PHOSSA, in *Ornithology*, a name understood by some to express the whole genus of pigeons, but more properly it is the name of one species only, the *columba turgetina*, or RUNT-DOVE.

PHOTINX, φωτιγξ, in *Antiquity*, a kind of flute in use among the Greeks. It was the same with the *plagiaulis* of the Romans.

PHOTINIANS, in *Ecclesiastical History*, a sect of ancient heretics, in the fourth century, who denied the divinity of Jesus Christ.

They took their name from *Photinus* their chief, who was bishop of Sirmium, and a disciple of Marcellus. This prelate published, in 343, his opinions concerning the Deity, which were equally repugnant to the orthodox and Arian systems. He maintained, that Jesus Christ was born of the Holy Ghost and the Virgin Mary; that a certain divine emanation (which he called the Word) descended upon this extraordinary man; that on account of the union of the divine word with his human nature, Jesus was called the Son of God, and even God himself; and that the Holy Ghost was not a distinct person, but a celestial virtue proceeding from the Deity. He was condemned by both parties in the councils of Antioch and Milan, held in the years 345 and 347, and by the council at Sirmium in 351. He was afterwards degraded from the episcopal dignity, and died in exile, in the year 372 or 375. His opinion was afterwards revived by Socinus.

PHOTOSCIATERICA, a term, which some authors use for the art of DIALLING.

The name is derived hence, that the art not only shews the hours by the shadow of a gnomon, whence it is called *sciatherica*, from σκια, *shadow*; but sometimes also by means of the sun's light, as in spot dials, reflecting dials, &c. from φως, *lux*, *light*.

PHOXINUS, in *Ichthyology*. See ROACH and MINNOW.

PHOXOS, φοξος, one with an acuminated or fastigiated head, that is, sharpened towards the top; the eminences of the forehead or occiput, or both, being depressed, or one or both of those parts beyond measure prominent. But *phoxi* are properly those who have the top of their head very much fastigiated and turbinated, and consequently deformed. Thersites is described in Homer with such a head.

PHRANIAN, in the *Botanical Writings of the Ancients*, a name given to a kind of *amomum* used in making garlands and other ornaments.

PHRASE, *phrasis*, φρασις, of φραζω, *I speak*, in *Grammar*, an elegant turn or manner of speech, peculiarly belonging to this or that occasion, this or that art, or this or that language.

Thus we say, an Italian *phrase*, an eastern *phrase*, a poetical *phrase*, or a rhetorical *phrase*.

A few elegant *phrases*, pertinently applied, are an ornament of discourse; but, if they come too thick, they have an ill effect, and make the style savour of affectation.

PHRASE is sometimes also used for a short sentence, or small set or circuit of words, constructed together.

In this sense, Father Buffier divides *phrases* into *complex* and *incomplex*.

PHRASES are *complete* where there are a noun and a verb, each in its proper function; i. e. where the noun expresses a subject, and the verb the thing affirmed of it. *Incomplete phrases* are those, where the noun and the verb together only do the office of a noun, as consisting of several

verial words, without affirming any thing, and which might be expressed in a single word.

Thus, *that which is true* is an incomplete *phrase*, which might be expressed in one word, *truth*: as, that which is true satisfies the mind; *i. e.* truth satisfies the mind.

PHRASE, *phrasis*, Fr. in *Music*, denotes the continuance of an air or harmony, which forms, without interruption, a sense more or less complete, and which is terminated by a cadence more or less perfect. In melody, the *phrase* is constituted by the air; but in harmony it is a regular series of concents, united together by dissonances expressed or understood.

PHRASEOLOGY, *phraseologia*, Φρασεολογια, a collection of the *phrases*, or elegant expressions, in any language.

PHREATTS, or PHREATTIUM, in *Greek Antiquity*, a court pertaining to the civil government of Athens, which was situated upon the sea-shore in the Piræus, and derived its name ἀπο τῶ φρεατος, because it stood in a *pit*, or, as others suppose, from the hero Phreatus. The causes heard in this court were such as concerned persons that had fled out of their own country for murder, or those that fled for involuntary murder, and had afterwards committed a deliberate and wilful murder. The first person that was tried in this place was Teucer, upon a groundless suspicion, that he had been accessory to the death of Ajax. The criminal was not permitted to come to land, or so much as to cast anchor, but pleaded his cause in his bark, and if found guilty, was committed to the mercy of the winds and waves, or, as some say, suffered there condign punishment; if innocent, he was only cleared of the second fact, and, according to custom, underwent a twelve month's banishment for the former. Potter's Gr. Antiq. vol. i. p. 111.

PHRATRIARCHUS, Φρατριαρχος, among the Athenians, a magistrate that presided over the *phratria*, or third part of a tribe. He had the same power over the *phratria*, that the PHYLARCHUS had over the tribe.

PHRENES, Φρενες, in *Anatomy*, the DIAPHRAGM.

It was thus called by the ancients, from φρην, *mind*; because they imagined this to be the seat of the rational soul: Hence,

PHRENESIS, *phrenesis*, or distraction. See PHRENSY and PARAPHRENESIS.

PHRENETIC *nerves*, called also *diaphragmatic* and *stomachic nerves*, are nervous branches derived from the cervical nerves, which, joining in a trunk, run through the mediastinum undivided, till arriving near the diaphragm, they again divide, and send off divers branches, some into the muscular, others into the tendinous part thereof.

PHRENIC *vessels*, an appellation given to a vein and some arteries of the human body, from their passing through the DIAPHRAGM.

The *phrenic* artery arises out of the descending AORTA, and distributes itself into the diaphragm and pericardium. See *Tab. Anat. Angeiol. fig.* 1. *n* 40.

The *phrenic* veins are two veins, which the descending CAVA receives immediately after its piercing the diaphragm. See *Tab. Anat. Angeiol. fig.* 6. *litt.* qq.

PHRENITIS, *phrenitis*, from φρην, *mens*, the *understanding*, or, as some will have it, from φρες, the *diaphragm*, because the ancients supposed it to have its seat in that part, in *Medicine*. See PHRENSY.

PHRENSY, in *Medicine*, a constant and vehement delirium, or distraction; accompanied with an acute fever, raving, waking, &c.

It differs from the *mania* and *melancholy*, as these are without fevers.

Physicians generally make the *phrenitis* to consist in an inflammation of the meninges of the brain; and distinguish it from the *peripneumonitis*, which they suppose to be an inflammation of the diaphragm.

Willis will have them the same disease, and both to consist in an inflammation of the animal spirits. He only distinguishes them as the inflammation arises from the cerebrum alone, or from the cerebrum and cerebellum together; and concludes, that they both arise in a fever, from the boiling blood's throwing its adust recrements into the brain.

Boerhaave makes the *phrenitis* either *vera*, wherein the cerebrum, or meninges, or both, are inflamed; or *spuria*, wherein the matter of a fever is translated into the cerebrum.

The true one either kills on the third, fourth, fifth, or seventh day; or it changes into a mania, lethargy, coma, &c. tremors, gnashing of the teeth, and grumous blood distilling from the nose in this case, are prognostics of death.

The disease is most frequently the effect of inflammatory or malignant fevers; though it sometimes arises from a suppression of the natural evacuations, as the menses, &c. When it succeeds an inflammation of the lungs, of the intestines, or of the throat, &c. it is owing to a translation of the disease from those parts to the brain, and generally proves fatal.

The preceding symptoms of this disorder are, long watchings, troubled sleeps, and very restless dreams, acute and terrible pains of the head, redness of the eyes, fiery look of the face, an entire forgetfulness of every thing, and a wandering of the mind, discovering itself by inconsistent answers to questions, a small delire of liquors, though the heat of the mouth plainly indicates all that can occasion the most intense thirst; dryness of the skin; large and slow respiration, a weak and slow pulse, singing of the ears, a small dropping of blood from the nose, watchfulness, suppression of urine, and an extreme sensibility of the nervous system.

All these signs predict an approaching *phrenitis*; but when it has already seized the patient, the blood-vessels of the head all swell, and the temporal arteries have so strong a pulsation, that they seem to beat very forcibly; the eyes sparkle and look wild and fierce; the talk is all wild and raving; and at certain times the patient has usually violent fits of struggling to get out of bed; the extremities are cold, and the urine thin, white, and pellucid. When the brain itself is inflamed, the pulse is always soft and low; but when the inflammation only affects the integuments of the brain, viz. the dura and pia mater, it is hard. Though the tongue is often black and dry, yet the patient seldom complains of thirst, and even refuses drink. A constant trembling and starting of the tendons is an unfavourable symptom; as are also a suppression of urine, a total want of sleep, a constant foaming, and a grinding of the teeth. The favourable symptoms are, a free perspiration or sweating, a copious discharge of blood from the nose, the bleeding piles, and a plentiful discharge of urine, which lets fall a copious sediment. Sometimes the disease is carried off by a looseness, and in women by an excessive flow of the menses.

The persons most subject to a *phrenitis* are those of a sanguineous and plethoric habit, and such given to anger; such as are addicted to a hot diet, and the use of strong liquors; such as are many hours together exposed to the sun in hot weather in their daily occupations; and such as have been subject to violent head-aches, or have had habitual hæmorrhages at the nose stopped upon them, or have had the blood usually discharged by the hæmorrhoids thrown up into the head; and women who have had the menses stopped upon them, and the blood to the same manner thrown up into the head. These persons are, from such circumstances and accidents, subject to the *phrenitis* as an idiopathic distemper, dependent on no other. But, besides these, others are also very subject to it as a symptom in other diseases. People in acute fevers are very often thrown into it by an incomplete critical congestion of blood about the head; and this principally happens to such as have been treated by apothecaries in an improper and injudicious manner. From the sudden checking of sweats, many also have been thrown into it, and some from improper bleedings, and more than all these by a too hot regimen.

An inflammation of the brain is sometimes the consequence of hard study, anxiety, or grief; of repellent or improperly used in an erysipelas, and of external injuries in the head.

Method of cure. In the cure, two things are chiefly to be attended to, viz. to lessen the quantity of blood in the brain, and to retard the circulation towards the head. A clyster is one of the first things to be prescribed in this case; or, if this cannot be given, from the violence of the patient, the bowels must be gently relaxed by large draughts of warm emollient liquors, with a small addition of nitre; after this bleeding is to be ordered, where the pulse and condition of the patient shew it to be necessary, and gentle diaphoretics are then to be given in repeated small doses, such as the mixtura simplex highly camphorated, and the like; and, in the intermediate times, the violent emotions of the blood are to be quieted by the use of powders of nitre, tartar of vitriol, crabs eyes, and a small portion of cinnabar; these are to be given with cooling emulsions; a placid regimen must be observed, and the patient kept in a gentle perspiration; and external applications are sometimes of great service: such are spirit of wine and camphor, rubbed on the forehead and temples, and frictions, cataplasms of various kinds, and blisters laid to the soles of the feet.

Others in this case apply epithems to the forehead, either of the absolutely repellent kind, such as vinegar of roses, or of lavender; these are most proper in the beginning; and, if these do not succeed, the resolvents are left afterwards to be tried; such are spirit of wine and camphor, and spirit or tincture of saffron; bags of camphor and nitre in powder may also be applied; and if these fail, it is proper to put on leeches to the temples and behind

hind the ears; bleeding in the jugular vein is another method; and blisters are to be applied to the legs and arms, and sinapisms to the feet, composed of yeast and strong vinegar, with mustard-seed, nitre, and other ingredients of that kind; and, finally, when all these fail, an irritation of the nostrils to promote an hæmorrhage, and bleeding in the nose, as practised in Egypt, and some other countries, is proper. A discharge of blood from the hæmorrhoidal veins is likewise of great service, and ought by all means to be promoted; natural or artificial evacuations should be restored, if they have been stopped, or others substituted in their stead; and if the disease proves obstinate, a blistering plaster should be applied to the whole head.

With regard to regimen, the patient should be kept quiet, and amused and soothed as much as possible. His aliment ought to be light, consisting chiefly of farinaceous substances; and his drink small, diluting, and cooling. Junker, Hoffler, and Buchan.

Dr. Freind has recommended bleeding at the jugular veins, in a *peripneumony* coming upon a fever; but Dr. Langrish endeavours to prove the bleeding in this case to be rather hurtful; and he thinks the cases quoted by Dr. Freind to prove his opinion, either do it not, or may be turned against him. See Med. Eff. abridg. vol. ii. p. 467.

PHRICODES, a term used by the ancients for a kind of fever, which is attended with a coldness and shivering, not only at the beginning of the fit, but at different intervals throughout its whole continuance. The semitertian fever is of this kind. The usual symptoms of these fevers are a remarkable lowness of the pulse, which is scarce to be felt, but recedes as it were from the finger; the belly is tumefied, and a rumbling noise is heard in it, and the tongue is very humid, and irrigated with a sharp acid humor, as with the saliva.

PHRONTIS, a word used by Hippocrates as the name of a peculiar disorder of the general nature of the melancholy affections. In this case the patient, he says, feels, as it were, a thorn pricking the abdominal viscera; he is extremely restless and uneasy, and always avoids light and company. He dreads being touched, and becomes timorous and afraid of every thing; he is molested with troublesome dreams, and imagines that he frequently sees spectres and frightful objects.

PHRYCTE, a word used by the ancient physicians as a name for common resin.

PHRYGANEA, in *Natural History*, a genus of the *neuroptera* order of INSECTS; the characters of which are, that the mouth is without teeth, the palpi are four, the stemmata three, the antennæ are longer than the thorax, and the wings are incumbent, the inferior being folded. Linnæus enumerates twenty-four different species. See CADE-*worm*.

PHRYGANICUS, in *Botany*, a term used by Dioscorides, and many other of the ancient Greeks, to express such herbaceous plants as have hard and woody stalks; such are the garden thyme, and several others of that kind. They also called these plants *xyloides*, *ξυώδης*, and *ξυώδεα φυτα*.

PHRYGIAN *mode*, in *Music*. See MODE, and DIAPASON.

PHRYGIAN *stone*, *Phrygius lapis*, in *Natural History*, the name of a stone described by the ancients, and used in their time in dying; probably from some vitriolic or aluminous salt contained in it, which served to enliven or fix the colours used by the dyers.

It was a light spungy mass, resembling a pumice, and the whitest and lightest were esteemed the best. Pliny gives us an account of their preparing it for use for dying, which was by moistening it with urine, and then heating it red hot, and suffering it to cool again: this calcination was repeated three times, and the stone was then fit for use; and Dioscorides recommends it in medicine after burning; he says it was drying and astringent.

PHRYGIANS, PHRYGES, or PHRYGASTÆ, as St. Epiphanius calls them, in *Church History*, were a branch of the MONTANISTS; so called from *Phrygia*, a country where they abounded.

They esteemed Montanus their prophet; and looked on Maximilla and Priscilla as great prophetesses.

This spirit of prophecy, or rather enthusiasm, was their distinguishing character. See CATAPHRYGIANS.

PHRYMA, in *Botany*, a genus of the *didynamia gymnospermia* class; the characters of which are, that it has only one seed. There is one species.

PHTHIRIASIS, *φθειριασις*, formed from *φθειρ*, *louse*, in *Medicine*, the morbus pediculosus, or lousy disease, wherewith children, and even sometimes adults, are afflicted.

Its cause is in the seeds or ova of that vermin laid in the cuticle, which here, happening to prove a proper nidus, cherishes and fosters the seed so as to hatch it.

The linen cloths, used by goldsmiths to wipe their vessels with after gilding, are excellent against the *phthiriasis* on account of the mercury they contain: they are to be applied by rubbing the child's head.

A good diet and cleanliness conduce much to the destruction of lice. When they are in the head, let it be combed every day, and, after combing, washed with the following lotion; viz. ℞ Staph. agr. vel. coq. Ind. contus. ℥i. aq. font. ℔ iß. & colatum adde acet. clavel. ℥ß; or, instead of this decoction, sprinkle the pulv. fem. staph. agr. vel. cocul. Ind. among the hairs every night, and confine it with a night-cap. The body lice are destroyed by any bitter, sour, salt, or mercurial medicine, applied to the skin. The black soap, and the flowers called cardamine, or lady's smock, are said to be specifics in all cases of lice on the human body.

PHTHIRION, in *Botany*, a name used by some authors for the *pedicularis*, or *red rattle*. See LOUSE-*wort*.

PHTHISIS, *φθισις*, in its general sense, denotes any kind of consumption of the body, in what part soever it be seated, or from what cause soever it arise.

Thus we have a nervous *phthisis*, and renal *phthisis*, dorsal *phthisis*, pulmonary *phthisis*, &c.

PHTHISIS, in its proper sense, is restrained to a pulmonary consumption, or a consumption arising from an ulcer, or other disorder of the lungs, accompanied with a slow hectic fever, which wastes, exhausts, and consumes the muscular flesh.

This disease is properly an ulcerous disposition of the lungs, taking its origin from a stasis of blood in that viscus, which in time degenerates into matter, and which is attended with a very remarkable wasting of the flesh, and loss of strength. A *phthisis* in different persons, and at different times, differs in degree; in some cases it is only a tendency to ulceration in the lungs, but in others it is an actual ulceration in that part.

In the first of these cases, where there is only a tendency to an ulceration, the lungs are only stuffed up with a quantity of tenacious and viscid matter, or of a mucous fluid, with a mixture of blood. This matter, by degrees, becomes more and more hard and tough, by the dissipation of its more fluid parts; and hence gives a scirrhous hardness to that part of the lungs where it is contained, but is not easily changed into absolute matter. In this case the patient may live many years, and often there is no suspicion of his being in a *phthisis*.

In the second case, or an actual exulceration of the lungs, the disease cannot long remain unknown, but the hectic fever, which is its constant attendant, readily discovers it; and the wasting of flesh, and spitting of matter, soon bring the patient to his end, if speedy and efficacious remedies are not applied.

Many are very anxious about the distinguishing a true *phthisis* from an abdominal hectic: but this is a distinction of very little use in practice, since both cases require the same regimen: the gently resolvent and discutient medicines, and balsamics, which have nothing acid in them, are the proper method in a *phthisis*, and are equally necessary in this hectic. The principal difference, however, between them, are these: the abdominal hectic always is attended with a fever, whereas the *phthisis* is often free from a fever, or at least is not attended with one of any consequence: if, in a strong inspiration, on drawing as much breath as may be into the lungs, the cough is always brought on, and there is a pain and straitness in the breast, that also declares the seat of the disorder to be in the lungs.

Atrophies are also much of the same nature with a *phthisis*, differing only in regard to the part they affect, and to the age of the patient. An atrophy is an injury of the glands of the mesentery, pancreas, or liver, and is common to infants; whereas the *phthisis* is a like distemperature of the lungs, and affects persons nearer the time of their growing to man's estate.

A true *phthisis* is, however, to be carefully distinguished from that marasmus which frequently affects old persons: this arises from many different causes, but never from that of a *phthisis*, or distemperature of the lungs. The vomica pulmonum is also by some confounded with a *phthisis*, but improperly; for though these distempers are nearly allied to one another, and often degenerate into each other, yet their origin is different. The *phthisis* takes its origin from an ulcer, properly so called; the vomica is an abscess, or imposthumation. The ulcer in a *phthisis* affects the humid parts of the lungs, where there is least blood; the vomica, on the contrary, is always seated in those parts where there is most abundance of blood; since it generally happens, that a vomica is a shorter disease in its period, and carries the patient off earlier; the *phthisis* does it more slowly and gradually. When a vomica, indeed, does not carry off the patient at first, it usually degenerates into a true *phthisis*; and, on the other hand, when the matter lodged in the lungs

in a true *phthisis* is so acrid as to corrode the vessels, then a vomica pulmonum often comes on in the course of that disease; but these are accidental degenerations of one disease into another; and though the first case is frequent, the other is more rare.

PHTHISIS, *true or a.* This disease, when it begins slowly and gradually, has scarce any signs at all by which it may be known: the utmost symptom of it in this case, is a dry cough, which, though not violent, will not be cured. This cough, by degrees, increases, and holds the patient always, in spite of medicines: in some cases it is moderate, but in others it becomes in a little time very violent. This cough is in some attended with a considerable spitting, in others with very little, and in some persons, both at the beginning and end of the distemper, with no spitting at all.

It is, however, a vulgar error to suppose every cough attended with spitting to be a consumption; for very frequently the faults of the first concoction will give origin to coughs more violent, and attended with a greater spitting than those in a genuine *phthisis*. Hence, for the proper distinguishing of a *phthisis*, many other symptoms are necessary: these are, that the patient be of an age suited to this disease, in general, between fifteen and thirty-five: the cough also, in a true *phthisis*, is continual, and always becomes much more violent on being exposed to the cold, as also on drawing the breath very deeply, or taking the effluvia of any acrid substances; and it is often accompanied with a disposition to vomit after eating; when the matter seems fetched up from a great depth, and is streaked with blood, of a faltish taste, and of an ill smell, and approaching to the nature of matter, this also denotes the case to be a true *phthisis*. This disease is always attended also with a decay of strength, a fenfation of ftraitnefs in the breaft, efpecially after motion, a more than ufual degree of heat, efpecially in the palms of the hands, and a flufhing of the face after eating, a want of appetite, or a defire for nothing but cold foods and drinks. The fleep in this cafe alfo rather tires and weakens than refreshes the patient, and the mouth is dry, the faliva glutinous, and the temper unufually peevifh, and affected ftrongly at trifles; the body alfo becomes extremely fenfible of all changes of the weather. The patient is apt to be fad, his appetite is bad, and his thirft great; the pulfe is generally quick, foft, and fmall; though fometimes pretty full, and rather hard. If thefe fymptoms happen in a cafe where there is either an hereditary difpofition to a *phthifis*, or where there has been any prior injury done to the lungs, there is no room to doubt but that the cafe is a true confumption or *phthifis*.

Thefe prior injuries of the lungs may be either from preceding difeafes, fuch as a fpitting of blood, a peripneumony, or the like; or from external contufions or wounds of the breaft; or, finally, from frequently being among the vapours of corrofive fubftances; and when thefe are attended with a hectic, or lofs of flefh in the whole body, and particularly in the face, there is not the leaft room to doubt but that the cafe is a dangerous *phthifis*. The fpitting of purulent matter is one of the moft certain figns of a perfect *phthifis*, but it is not an univerfal one; for there are fome cafes in which the bronchia and membranous portions of the lungs only are affected, in which a *phthifis* may arrive at its greateft degree with-out any fuch fpitting. It is alfo to be obferved, that the common thick, yellowifh, or greenifh matter, which is frequently voided in large quantities in fimple coughs, is not to be confounded with the purulent matter voided in a continued *phthifis*.

The urine of people in this difeafe is ufually very like that of perfons in health, except that it retains its froth longer: this, however, is no certain fymptom of the difeafe; for it frequently happens in cafes of fimple colds, in people of phlegmatic habits.

If a vomica pulmonum comes on from a *phthifis*, the fever, which was before a flow one, aflumes the appearance of an acute one; and the pain that attends the cough becomes more violent, and refpiration more difficult; finally, colliquative fweats, and diarrhœas, and an exceffive difcharge of urine, are very fatal fymptoms, ufually appearing towards the laft ftages.

PHTHISIS, *perfons fubject to a.* Thefe are principally young people of a plethoric habit, accuftomed to perfect health, and of found conftitution, particularly fuch as live idle lives. Thofe who labour hard, or are of a fcorbutic or phlegmatic habit, are more than all others free from this difeafe. Perfons who are fubject to hæmorrhages of any kind, or to violent pains in the head, and thofe who find their breath very fhort after a little exercife, and particularly fuch as have had at any time fpittings of blood, are moft fubject to this diftemper; as thofe, on the contrary, who are fubject to catarrhal defluxions, to fimple coughs, or to diarrhœas, or cutaneous eruptions, or external ulcers, are ufually free from it. Women in general are much more expofed to it than men; and that for the plain reafon: the fuppreffion of any habitual hæmorrhage endangers the patient as to this difeafe; and women are well known to be more fubject to evacuations of blood than men; and alfo to the fuppreffion of thofe evacuations.

Old people are very feldom found to have *phthifes*, unlefs they arife from violent external injuries; and very young perfons are as feldom liable to them, unlefs from fuppreffion of large and habitual hæmorrhages by the nofe.

PHTHISIS, *remote caufes of.* The remote caufe of this difeafe is a plethoric habit; the proximate caufe is a congeftion of florid, ruddy or ferous blood, in the breaft. The occafional, or accidental caufes, are either external injuries from blows, falls, or bruifes on the breaft, a violent cough in the autumn, at which feafon the air is peculiarly bad for all perfons inclined to a *phthifis*; a conftant or unwholefome air, violent paffions, great evacuations, the abufe of fpirituous liquors, the immoderate ufe of venery, the receiving the fumes of corrofive medicines, and, finally, the improper cure of other difeafes, particularly the fuppreffing of fevers and hæmorrhages by aftringents, without any previous cautions. An hereditary difpofition is alfo frequently in fault; the cough which attends this difeafe is only an effort of nature to break through the congeftion in the firft ftages, and, in the latter, to throw up the matter occafioned by it; to which we may add, that particular occupations contribute to this difeafe.

Sydenham obferves, that the heavieft *phthifes* ufually have its origin in the winter's cold; from a fharp humour trickling down upon the lungs, where, like a catarrh, it irritates them fo as to raife a cough.

This, by degrees, brings on other fymptoms; as a fpitting, firft, of a vifcid pituita, then a heavy fetid puftion of pure blood, and fometimes of the very fubftance of the lungs, raifed by a long exulceration: with night-fweats, falling off of the hair, and finally a colliquative flux, which is foon followed by death. The fame author adds, that the *phthifis* kills two thirds of thofe who die of chronic difeafes.

Dr. Arbuthnot obferves, that in his time conſumptions made up above one-tenth part of the bills of mortality in and about London; and it is well known, that this fpecies of difeafe prevails more in England than in any other part of the world; owing, perhaps, to the great ufe of animal food and ſtrong liquors, the general application to ſedentary employments, and the great quantity of pitcoal which is burnt here; to which may be added the perpetual changes in the atmoſphere, or the variableneſs of the weather.

In the laſt ſtage of the *phthiſis*, the feet and legs ſwell, the noſe appears ſharp, the eyes hollow, the temples fallen, the ears cold and contracted, the ſkin about the forehead hard and dry, and the complexion greenifh or livid, &c. This appearance is called the FACIES *Hippocratica*. See CONSUMPTION.

Among the cauſes of this diſeaſe may be reckoned intemperance, as it brings on a plethora or cacochymy, and alſo peripneumonies, aſthmas, pleuriſies, &c. Pitcairn adds, that the *phthiſis* frequently ariſes from an ill conformation of the breaſt; which is either natural, as when the breaſt is too narrow, the neck too long, &c. or accidental, where there happens a curvity or diſtortion of the breaſt. And he reckons among the ſpecies of *phthiſis* thoſe proceeding from the diarrhœa, dyſentery, gonorrhœa, hæmorrhages, and dropſy, and from many other diſeaſes; and perhaps there are many other remote cauſes which can produce a conſumption, without varying the common immediate cauſe of the diſeaſe, or the method of cure.

Prognoſtics in it. A true *phthiſis*, even in its beginning, is a dangerous diſeaſe, and admits but of a very dubious prognoſtic; but when in an advanced ſtate, it is always fatal. The reaſon of this is evident, becauſe there are in this caſe real ulcers in the lungs, and we well know that no ulcers can be cured till it is firſt perfectly cleanſed, and that it is not eaſy in an internal part; and, after that, the healing up of a wound in the lungs is ſcarce to be expected, as thoſe parts are continually diſturbed by the very drawing in and voiding the breath, and ſtill more ſo by the cough. There have been, however, inſtances of cures in the beginning of a *phthiſis*, in which there have been evident proofs of a reſtitution and conſolidation of the parts.

People of a dry habit are much ſooner carried off by it than thoſe of a moiſt one; as are alſo thoſe of a bilious diſpoſition, than thoſe of a more languid temper; and, finally, younger perſons uſually die ſooner in it, than thoſe who are more advanced in years. Women, as they

are more subject to a *phthisis* than men, so they are more easily cured. This distemper is often brought upon them merely from a suppression of the menses, and in that case it is often cured only by regularly bringing them again to their proper periods. The hectic fever in these cases is what hastens the death of the patient; for the less of that fever the patient has, the longer he lives under it.

When the spitting of true purulent matter is come on, and is attended with colliquative sweats and a diarrhœa, there is no further hope for the patient; and, in general, what is reported of the curing of consumptions, is founded on errors, and other cases have been ruthlessly so.

A diurnal cough becomes habitual, and attended with a raising of a thick, pulpy, greenish matter, is often mistaken for a consumption: as is also a slow fever, attended with copious sweats, and an extenuation of the body; or a recent hectic, arising from a continued slow fever; or a merely asthmatic disorder of the breast; or, finally, a hæmoptysis has been mistaken for a *phthisis*. In all the cases said to have been *recent*, and perfectly cured, either one of these has been the case, or the mere strength of nature, assisted by happy circumstances in the constitution, not to be expected from one person in a thousand, have carried the patient through it.

Method of cure. The general method in a genuine *phthisis*, is to reflect first the softening, ulcerating, and diffusing the ulcerous matter in the lungs; and after this to attempt the cleansing and healing of the ulcers; afterwards to relieve the hectic by analeptics, and to give the weakened parts their due tone again; and during this, the several symptoms, such as the cough, fever, &c. are to be palliated as much as may be.

To this end, in the beginning of the course, gentle laxatives are by all means to be given; such as small doses of rhubarb, with manna, tamarinds, and the like; and in subjects abounding with foul humours, jalap, scammony, and even mercurius dulcis, are found necessary; but this last medicine is only to be given with the utmost caution, for fear of a salivation. After a few doses of the laxatives, the resolvent, abstergent, and diffusient medicines, are to be given for several weeks together; such are, decoctions of pimpernel, cinquefoil, burnet, iris, birth-wort, and fruits of juniper, with maidenhair, horehound, hyssop, and dwarf-elder: the gum ammoniac are also to be given in small doses; such as ammoniacum, sagapenum, and the like; and mixtures of crabs eyes saturated with lemon juice, with vitriolated tartar dissolved in the pectoral waters, are to be given every day three or four times; a little nitre, cautiously given in the intermediate time, will also be of great use in abating or taking off the fever.

The cough, in the first stage of a *phthisis*, may sometimes be appeased by bleeding, and the expectoration may be promoted by the following medicines. Take fresh squills, gum ammoniac, and powdered carduus seeds, of each a quarter of an ounce; beat them together in a mortar; and if the mass proves too hard for pills, it may be softened with any syrup. This may be formed into pills of a moderate size, and four or five of them taken twice or thrice a day. These ammoniacum is likewise a proper medicine in this stage of the disease. A mixture made of equal parts of lemon juice, sour honey, and syrup of poppies, may be used, by sometimes four ounces of each of these over a gentle fire, and taking a table-spoonful of it, when the cough is troublesome. Oily and balsamic medicines, though often recommended, are generally more injurious than beneficial. See BALSAMS, and Lond. Med. Obs. vol. ii. p. 231, and p. 280.

Acids seem to be peculiarly useful as well as grateful in this disease; and especially those of the vegetable kind, as apples, oranges, lemons, &c. The patient's drink may be infusions of the bitter plants, as ground-ivy, the lesser centaury, ramsons, or water trefoil. But if he has any blood, he ought to die, for his ordinary drink, infusions or decoctions of the emollient roots, plants, &c. and recourse may be had to the use of nitre. See DIAPHORETICS.

We may observe in general, on the authority of Dr. Fothergill, that in the beginning of the disease, the most demulcent and cooling medicines are indicated; and when the symptoms of inflammation are abated, gentle anodynes will be useful. The common emulsion, made with good fresh sweet almonds, as a very proper vehicle for the several remedies indicated in this complaint; or an excellent emulsion may be prepared with fruit white poppy seeds, in the proportion of half an ounce to a pint of distilled or pure water. With regard to regimen, when a cough begins, to which every prudent and attentive physician cannot be direct too soon, if the patient is very young, the quantity of diet, especially of solid, must be lessened, and the deficiency made up with warm fomentings. Barley water, milk and water, thin gruel, and the lighter broths, should be used. The patient should keep chiefly to the use of vegetables and milk. After milk ought to make a considerable part of his food; this should be drunk in its natural warmth, and in a greater portion, in the quantity of half a pint, four times, or at least thrice, in a day; and if it should happen to purge, it may be mixed with old conserve of roses, or powder of crabs claws. Women's milk has been recommended in preference to any other. Buttermilk has also been of service; and cow's milk, with the addition of an equal quantity of barley-water, or a tablespoonful of rum or brandy to half a pint is proper, and may prove beneficial. Rice and milk, or barley and milk boiled, with a little sugar, is very suitable too; ripe fruits roasted, baked, or boiled, are likewise proper; the jellies, conserves, and preserves, &c. of ripe, subacid fruits, ought to be eat plentifully, as the jelly of currants, conserve of roses, preserved plums, cherries, &c. Such a course of diet, with wholesome air, and proper exercise, particularly on horseback, or a sea-voyage, is the most to be depended upon in an incipient consumption. In the further progress of this distemper, should the course above recommended fail, medicines of a different class are found of advantage; such as the bark, elixir of vitriol, Bristol, and other waters, and a total abstinence from animal food. When the spitting up of proof matter, expression of the breast, and the hectic symptoms indicate an impatthisme formed in the lungs, an ounce of the Peruvian bark in powder may be divided into eighteen or twenty doses, and one of them taken every three hours in the course of the day. If the bark should purge, it may be made into an electary with the confection of roses. Those who cannot take it in substance may infuse it in cold water, in the proportion of half an ounce of the powder to half a pint of water, and a common tea-cup full may be taken three or four times a day. The bark, however, should not be used, as long as there are any symptoms of an inflammation of the breast. After this, the healing the ulcerated parts is to be attempted by the more temperate balsamics; such as boiled turpentine, mastic, calamus, balsam of Peru and capiv, and Locatelli's balsam: with these there always must be joined such things as will nourish and give strength; such are emulsions made with fresh sweet almonds, with jellies, and conserves of roses.

If the violence of the disorder is found to resist on this method, it will be proper to give a mixture of spirit of sal ammoniac, with tincture of sal of tartar, in doses of about twenty drops, three times a day: this is greatly serviceable in resolving the parts to their due tone; and if the cough still continues violent, it will be proper to give small doses of the Borax pill at night. If the disease is finally taken off by this method, it will be proper afterwards, by way of prevention, to bleed frequently in the foot every spring and autumn; to recall, by all possible means, any habitual discharges of blood that had been stopped or suppressed; and, particularly in men, to promote a discharge by the hæmorrhoidal veins, by applying leeches to the part; the patient is not to be loaded with medicines in this case, but it will be sufficient always to keep the bowels moderately open, and to use moderate but not violent exercise, with diets that are soft and easy of digestion.

Nor do Hault and others to prove, that a consumption of the lungs always depends on tubercles, and that an ulcer there is only an effect of these tubercles; and when the disease is in its full fashion, and incurable, it then only becomes contagious, by small worms, which it communicates to others. The same author is for preparation for consumption, before it comes to the last degree, is to restore the tubercles with mercury, flesh, milk-plants, and the spanish and antihemetic plants. He remarks, that the liver is generally hard in this disease: and therefore he applies a warm emmenial plaster to the right hypochondriac region, rubbing some mercurial ointment every night on the skin of that part; then continues in the use of tabids made with flesh, mumpodes, bdellium, coral, and crabs eyes, of each half an ounce; cinnamon, three drachms; sugar, half a pound; these all with the mucilage of gum tragacanth, in the quantity of one cup of water.

The use of these tablets is to a drachm, morning and evening, rubbing it down with a pestle made of the root of mallow, two ounces of the juice of wormwood, and as much juice of chervil. Sweet oil fasten. He says, this method, with riding, has often been successful.

Dr. Cheyne thinks that a total milk and fruit diet, with frequent phlebotomies, vomits, bark in the morning, and rhubarb at night, will fairly cure consumptions.

This distemper, according to some, is principally to be cured by frequent bleedings in small quantities. Med. Ess. Edinb.

Sydenham ascribes the defluxion on the lungs, in the first stage, to be abated by blood-letting, &c. and pectorals to be used, accommodated to the various states of the disease, viz. incrassantia, attenuantia in village the hectic, &c. with emulsions, olives milk, &c. and ballamics to cure the ulcer. That the other assistance in this disease is to be expected from riding cautiously on horseback; be lets, the patient need not confine himself to any less or duty, &c. The whole, he adds, if used in time, is as much as sure a cure for a *phthisis*, as the cortex is for an intermitting fever.

Dr Barnard recommends butter-milk as an admirable succedaneum to asses milk. Milton Frys, he knows of no medicine, either internal or external, so good against fresh ulcers of the lungs, as balsam of sulphur, especially when prepared with oil of anise.

Etmuller observes, that the cough of *phthisical* people is, at first, only stomachical; but that at length it becomes pulmonary. He adds, that vomitories are good in a beginning *phthisis*, and that purgatives, by all means, are to be avoided; and commends the use of medicines made of tobacco, not only as they promote expectoration, but as they are vulnerary.

It is a common observation, that in those countries where they burn turf, people are rarely affected with the *phthisis*; which Willis ascribes to the sulphur abounding therein, and accordingly recommends tincture of sulphur as the best remedy he knows of in any cough without a fever; adding, that a fumigation, or mortifer, of sulphur and arcuile has also frequently proved a cure in the most desperate *phthisis*.

Bennetus holds the *phthisis* to be contagious; and that there are frequently instances of its being communicated by stools, linen, beds, &c.

Fuchsius recommends mercurius dulcis in the beginning of a *phthisis*. And Berhaave and Colbatch affert, that, contrary to the opinion of most authors, they have frequently cured scabs, with great success, in the *phthisis*.

PHU, in *Botany*, a name by which some authors call the great garden valerian.

PHYCIS, in *Ichthyology*, the name of a fish of the mullaceous kind, more usually called CALLYRIAS, or *asellus callaritus*, and *lucca marina*, or sea-tench.

PHYCIS, in *Ichthyology*, is also a name given by Arteni, after Ariftotle, Pliny, and the reft of the ancients, to a fish nearly allied to the genus of the *blenni*, and called by fome *trahias* and *phycis*; and, according to Rondeletius, the TINCA *marina* of the Italians. Salvian, however, thinks that it is the *tinca marina*, and the matter is yet undecided among the writers on this fubject.

PHYCITES, in *Natural Hiftory*, the name given by the ancients to a ftone which had the impreffion of a fea-plant on the furface of ufual kind; probably in the manner in which our black coal ftate is frequently found to contain the impreffions of fern and other vegetables.

PHYGETHLON, φυγεθλον, derived from φυω, *I breed*, or *engender*, in *Medicine*, is defined by Celfus, a hard, flat tumor, fomewhat refembling a puftule; occafioning an intenfe pain, and fometimes a fever.

The *phygethlon* only differs from the PHYMA, in that it does not rife fo high; it ripens very flowly, and produces but little pus.

The Latins call it *panus*, or *pamus*, and fometimes *furunculus*. Gorræus defines the *phygethlon* a phlegmon, arifing on the glandulous parts, efpecially about the neck, armpits, and inguina; in which laft place it is called a *bubo*. The *phygethlon* has the fame caufes, and the fame fymptoms, with the common BUBO. It frequently arifes after fevers, and pains of the belly; and is cured like other inflammatory tumors.

PHYLACISTÆ, among the *Romans*, officers to whofe keeping the faves in prifons and work-houfes were committed.

PHYLACTERY, φυλακτηριον, in *Church Hiftory*, a flip of parchment, wherein was written fome text of holy Scripture, particularly of the Decalogue; which the more devout people, among the Jews, inclofed in leather cafes, and bound with thongs on the forehead, and on the left arm. See FRONTAL.

They derived their name from φυλαττω, *I keep*, either becaufe they were fuppofed to preferve the law in memory, or rather, becaufe they were looked upon as a kind of amulets or charms to keep them from danger.

They were called תפלין *tephilin* by the Jews.

PHYLACTERY, in the general, was the name given by the ancients to all kinds of charms, fpells, or characters, which they wore about them, as amulets, to preferve them from dangers or difeafes.

The primitive Chriftians alfo gave the name *phylacteries* to the cafes wherein they inclofed the relics of the dead.

PHYLARCHUS, φυλαρχος, among the Athenians, *phylarchs* were magiftrates who had the care of them the remainder of a tribe committed to his charge; and whofe bufinefs was to take care of the public treafure belonging to each tribe, to manage all their concerns, and call them together as oft as anything happened that required the prefence of the whole body.

PHYLATERIA, a name given by fome botanical authors to the *fedum*, or poly-cotyledon.

PHYLICA, *Laurel alaternus*, in *Botany*, a genus of the *pentandria monogynia* claſs. Its characters are, that the perianthium is tubulated, and divided into five fegments; it has no petals; the five ſtamina are defcribed by fcales, and the fruit is a three-berried capſule. There are five fpecies.

PHYLLANTHUS, in *Botany*. See *Sea-side* DARNEL.

PHYLLIS, *ſpecies nulla, auricula muris* kind, in *Botany*, a genus of the *pentandria digynia* claſs. Its characters are three: the compliment of the flower is compoſed of two leaves fitting on the germen; the flower has five ovated fpear-fhaped petals, which turn backward; it has five ſhort hair-like ſtamina, terminated by oblong ſummits; the germen, which is ſituated under the flower, has no ſtyle, but is crowned by two awl-fhaped, reflexed, hairy ſtigmas, and turns to an oblong angular fruit, containing two parallel ſeeds, covered on their outſide, plain on the other, and bevel at the top. We know but one ſpecies, which is a native of the Canary Iſlands.

PHYLLITIS, in *Botany*. See HART'S-*tongue*.

PHYLLITIS *marina*, in *Natural Hiſtory*. See HART'S-*tongue*.

PHYLLOBOLIA, φυλλοβολια, in *Antiquity*, a cuſtom that prevailed among the ancients to ſtrew flowers and leaves on the tombs of the dead. The Romans adopted this cuſtom from the Greeks, and added likewiſe wool. See BURIAL.

The *phyllobolia* was alſo uſed on occaſion of a victory obtained at any of the public games; when not only the victors, but likewiſe their parents, were crowned with flowers and leaves.

PHYLOBASILEI, φυλοβασιλεις, among the Athenians, magiſtrates, who, with reſpect to particular tribes, had the ſame office that the *βασιλευς* had with reſpect to the commonwealth.

They were choſen out of the quarrelſome or nobleſt, for the care of public ſacrifices, and other divine worſhip peculiar to their reſpective tribes, and kept their court in the portico called *βασιλειος*, and ſometimes in the *πρυτανειον*.

PHYMA, φυμα, in *Medicine*, a roundiſh preternatural tumor, ariſing in the glandular parts, eſpecially under the lower jaw.

The *phyma* is ſmaller and ſmoother, leſs red and painful, than the PHYGETHLON.

It is eaſily cured in children, but more difficultly in adults; but in thoſe it is more rare. It is remedied by aſſiſting nature in the work of maturation, as, by a ſuppurating cataplaſm, &c. It is ſuppoſed to have its rife from putrified blood; and is moſt common in young children, where it frequently alſo ariſes from too rich food.

Gorræus obſerves, that ſome make *phyma* a general name for all tumors or ſpotthurnes, that maturate and ſuppurate readily, of what kind ſoever, as in whatſoever glandulous part they ariſe.

PHYRAMA, in the *Materia Medica*, a name given by ſome of the old writers to the gum ammoniacum, particularly to that kind of it which was ſoft and ductile between the fingers. It is not clear that the gum ammoniacum of their times was the ſame thing which we now know by that name; at leaſt it is certain, that the other kind of it, which they called *hermoniac*, or *ammoniacum thraſcium*, was not; for Diofcorides defcribes this as being of a reddiſh-brown colour, and very friable; and Avicenna ſays, that it is mixed a fine yellow or gold-colour upon paper. Theſe are properties by no means agreeing with our gum ammoniacum; and if juſtly applicable to that, muſt prove that it could not be the ſame; and the character given by Avicenna of its being eaſy, and making a yellow ſtain upon paper, ſeem to confute the ſuppoſition. This, however, by no means can agree with the other virtues attributed to it.

PHYSALIS, in *Botany*. See *Jerusalem* CHERRY.

PHYSALUS, a name given by Rondeletius to a ſpecies of ſea inſect, of the *fcolopendra marina* kind, ſuppoſed by ſome to be the ſame with the *ſcolopendra marina*, or *cipra*, of the antients, deſcribed by Mofquera; but this does not appear to be the caſe, on a firſt examiny. The *phyſalus* of Rondeletius has no mouth, whereas the *ſcolopendra* of Ireland has a remarkably large one; that of Rondeletius is wider in the middle, and tapers at each

end,

cold; but the little kind is furnished with the head, and rapers from thence all the way to the tail. Rondeletius, and others, on the back, but the Latin one has only fifteen fingers and toes; a peculiarity extraordinary, as of fourteen was found to the stomach of a cod-fish, which had eaten it for food. The figure given by Rondeletius agrees with our's well with the account he gives, but not with the figure of that drawn upon the face from the Indian fish, and given in the Philosophical Transactions. On the whole, nothing is more plain than that there are two different species of animals though of the same genus. See Tab. Zoology, n° xxx. See Monodon.

Physetus is found in Zoology. See Physeter.

PHYSETUS, in Zoology, the name of a genus of fishes of the abdominal kind, in the system of Artedi, but of the order of cete, and class of mammalia, in the distribution of Linnæus, the characters of which are these: the teeth are crooked, and are placed only in the lower jaw; there is one high fin on the back, and a fistula or hole on the forehead.

Artedi has described two species of this genus, the first of which, 1. The *physeter*, with the upper jaw longer than the under one, and with a long spine on the back. The head of this fish is large, that is, half as large as the body, and rather thicker than the middle part of it; the upper jaw runs out two feet beyond the under one, and is upon part more than five feet; the eyes are remarkably small, scarce larger than those of a bullock; the fistula or pipe is placed a little above the centre of the head; it is divided into two chambers, and covered with one common operculum; the teeth are in number forty-eight, and all of the shape of a triangular cone, smooth, and a little curved, thick and sharp pointed in the middle, and at the end terminating in a cone very sharp pointed; the back is thinner than the middle of the body. This is the *physeter macrocephalus* of Linnæus, which he says pursues and terrifies the *physeter* to such a degree as often to drive them on shore. It is called the Short-headed CACHALOT. 2. The *physeter* with a very high back fin, with the rays of the fourth fin. This is a species of whale, described, as well as the former, by Rondeletius. The head is very large in the fœtus, or young, as in the middle of the head; the fin flounds so high as the middle of the back, that it has been compared to the upper part of a dog. This is the *physeter longimanus* of Linnæus. Besides these, Linnæus enumerates two other species, viz. the CATODON, without a back-fin, and with the spout-hole at the extremity of the nose; and the *physeter macrocephalus* or CATODON, without a back-fin, and the spout-hole in the front.

The name *physeter* is of Greek origin, and is derived from the verb φυσαω to blow. It has this name from its quality of casting out a great quantity of sea-water, and then blowing it out again with great force and violence.

PHYSIC, or PHYSICK, *medica*, the art of healing; properly called *medicina*.

The word is formed from φυσις nature; because medicine consists principally in the observation of nature.

For the rise, progress, division, &c. of *physic*, see Medicine.

Physic, *hermetical*. See Hermetical.

Physic, *lunar*. See Lunar.

Physic nut, in Botany, the name of a species of the jatropha. See Curcas.

PHYSICAL, *physicus*, something belonging to, or really existing in nature.

In this sense, we say, a *physical* point, in opposition to a mathematical one, which has only existence in the imagination.

Or a *physical* hardness, or body, in opposition to spirit, or immaterial substance, &c.

Physical, or sensible horizon. See Horizon.

Physical *causes*, or *principles*, *causæ physicæ*, are those *agents*, *forces*, *powers*, *matter*, *motion*, *gravity*, *elasticity*, *fluidity*, *magnetism*, *fire*, *perspiration*, *digestion*, *putrefaction*, *fermentation*, *generation*, and *gravity*. See the several articles.

PHYSICIAN, a person who professes medicine, or the art of healing.

The ancients distinguished their *physicians* into various classes or sects, as,

Physicians, *dogmatic*, those who proceeded in a certain regular method, founded upon reason; declaring contemptuously against empirics. See Dogmatic.

Physicians, *eclectic*. See Methodists.

Physicians, *empiric*, those who laid down principles, and proceeded from those principles, and from experience. See Dogmatic.

Physicians, *expectant*, those who kept wholly to expectations, and excluded all use of medicine. Such were Asclepiades, Apollonius, Glaucias, &c. See Dogmatic.

Physicians, *rational*, were those who used their patients as beings to examine their cases.

They were thus called in opposition to the *empirics*, who used their medicines to the hazard, &c. See Empiric.

The moderns find all that although *physicians*, botanical persons, *anatomical physicians*, *chymical physicians*, pharmaceutical *physicians*, &c. besides *mechanical physicians*, *iatrophysicians*, or those who applied chymical medicines, and *iatrochymists*, or *galenic physicians* for the completion of *iatrochymists*, or *galenic physicians* for the completion of *iatrochymists*, or *galenic physicians* for the completion of

PHYSICS, *speculative*, or such as was couched in symbols: such was that of the old Egyptians, Pythagoreans, and Platonists, who delivered the properties of natural bodies under arithmetical and geometrical characters, and hieroglyphics.

Peripatetic, or that of the Aristotelians, who explained the nature of things by matter, form, and privation, elementary and occult qualities, sympathies, antipathies, attractions, &c. See ARISTOTELIAN and PERIPATETIC.

Experimental, which inquires into the reasons and natures of things from experiments: such as those in chemistry, hydrostatics, pneumatics, optics, &c. See EXPERIMENTAL *philosophy*.

And, finally, *Mechanical*, or *corpuscular*, which explains the appearances of nature from the matter, motion, structure, and figure of bodies, and their parts; all according to the settled laws of nature and mechanics. See MECHANICAL and CORPUSCULAR *philosophy*.

PHYSIOGNOMICS, a term used by some physicians and naturalists, for such signs as are taken from the countenance to judge of the state, disposition, &c. of the body and mind.

PHYSIOGNOMY, φυσιογνωμία, formed from φύσις, *nature*, and γνώμων, *I know*, the art of knowing the humour, temperament, or disposition of a person, from observation of the lines of his face, and the characters of its members or features.

Baptist. Porta and Robert Hudd are the last modern authors on *physiognomy*. The ancient ones are the foolish Adamantius, and Aristotle; the *physiognomy* of which last we have translated into Latin by de Laguna.

With respect to *physiognomy*, this, at least, may be said, that of all the fanciful arts of the ancients, diffused among the moderns, there is none less to much foundation in nature as this.

There is an apparent correspondence between the face and the mind; the features and lineaments of the one are directed by the motions and affections of the other: there is even a peculiar arrangement of the members of the face, and a peculiar disposition of the countenance, to each particular affection of the mind.

In effect, the language of the face, *physiognomy*, is as copious, nay, perhaps, as distinct and intelligible, as that of the tongue, speech.

The foundation of *physiognomy* is this; the different objects that present themselves to the senses, nay, the different ideas that arise in the mind, do each make some impression on the spirits; and each an impression correspondent or adequate to its cause: therefore each makes a different impression.

If it be asked, how such an impression should be effected, it is easy to answer, that it follows from the œconomy of the Creator, who has fixed such a relation between the several parts of the creation, as the end that we may be apprized of the approach or recess of things useful or hurtful to us.

The animal spirits, say the Cartesians, moved in the organ by an object, continue their motion to the brain; whence that motion is propagated to this or that particular part of the body, as is most suitable to the design of nature; having first made a proper alteration in the face, by means of its nerves, especially the pituitary, and oculorum motorii.

The face, here, does the office of a dial-plate; and the wheels and springs, withinside the machine, actuating its muscles, show what is next to be expected from the striking part.

Now if, by repeated acts, or the frequent entertaining of a favourite passion, or vice, whole natural temperament has hurried, or custom dragged one to, the face is often put in that posture which attends such acts as the animal spirits will make such potent passages through the muscles in which the efforts of an habit consists, that the face is sometimes unalterably set in that posture to the utmost resignous are by a long continued fitting in strange postures or their pagodity of, as itself, it falls, insensibly and mechanically, into that posture, under some peculiar object differs from others, or some dissimilitude hides it, and this reasoning, as has been said, is confirmed by observation; which, by being a little more accurate and minute, would serve to distinguish not only habits and tempers, but even professions. After all, this is a kind of science, which must be very precarious and deceitful.

PHYSIOLOGY, in *Botany*, those authors whose writings tend to set that study in its clearest light, by explaining and enumerating the various superfluities of the male and female parts in the flowers of plants.

PHYSIOLOGY, φυσιολογία, formed of φύσις, *nature*, and λόγος, *discourse*, or *reason*, the doctrine of nature, or natural bodies; called also PHYSICS, and *natural philosophy*.

PHYSIOLOGY properly denotes only an internal examination, discounting, which runs or terminates in the speculative or abstract contemplation of its object, viz. natural appearances, their causes, &c. and does not direct or prescribe rules for the *making* of natural *things*, as flames, plants, &c.

In which view, chemistry does not properly belong to *physiology*, but is a kind of counterpart thereto, as in many cases, imitating or mimicking nature, rather than considering and explaining her.

PHYSIOLOGY is more particularly used for a branch of medicine, which considers nature with regard to the cure of diseases; particularly the human body, its parts, structure, health, life, functions, œconomy, &c.

Physiology, in this sense, amounts to much the same with what we otherwise call the doctrine of the *animal œconomy*.

PHYSOCELE, a word used by many authors to express a *windrupture*. See PNEUMATOCELE.

PHYSTA, in *Ichthyology*, a name given by Gesner, and some others, to the fish called by the Greeks, and many of the later authors, BALLERUS and *ballerus*. Arteni denies its right to any generical name, reducing it to the genus of the esprini, to which it evidently belongs, and distinguishing it from the others of that numerous genus by the specific name of the very broad and thin *esprinus*, with forty rays in the pinna ani.

PHYSTE, in the *History of the Ancient Physicians*, a word used to express a mass of meat macerated in a *cadus* filled with wine, but not fit to ferment.

PHYTEUMA, in *Botany*, the RAMPION.

PHYTALIA, a word used by the ancients in two very different senses; with some expressing the latter part of the winter season, and with others a place where vines are planted, whether in standard vineyards or otherwise.

PHYTOLACCA, in *Botany*. See POKE-WEED and CURTIFARE.

PHYTOLOGI, φυτολόγοι, authors who have written any rectile anatomy, or the history or cures of vegetables.

PHYTOLOGY, φυτολογία, compounded of φυτὸν, *plant*, and λογος, *discourse*, or λόγος, *I discuss*, or *reason*, a discourse upon plants; or a description of their forms, kinds, properties, &c.

PIA *mater*, in *Anatomy*, called also *mater tenuis*, and *meninx tenuis*, a fine coat, or membrane, immediately investing the brain, and lying under the DURA mater. It is a fine thin membrane adhering so closely, and insinuating itself in such a manner, into all the folds and extravasation parts of the brain, that it is scarce to be separated from it. This membrane covers the whole brain, cerebellum, and medulla oblongata; and serves together with the joint, for the defence of the BRAIN, and the supporting of vessels.

The *pia mater* is formed of two very fine lamellæ, the outermost of which covers pretty uniformly all the convex surface of the brain, and lines in the same manner all the concave or inner surface of the DURA *mater*. The internal lamina forms a great number of plexus, duplicatures, and folds, which insinuate themselves into all the folds and circumvolutions, and between the different strata of the cerebrum and cerebellum. These two laminæ are connected only by a cellulous substance, which accompanies them through their whole extent, except in those parts of the basis of the cerebrum, &c. where the whole internal lamina containing its interstices, the external remains uniformly stretched over the processes, and the interstices of which are entirely separated from the other laminæ without any cellular substance between them. These separate portions of the external lamina have led some to consider it as a third membrane of the brain, distinct from the *pia mater*, and it has been called membrana ARACHNOIDEA, WILLIS. Phil. Anat. Cerebri, cap. 2. Lit. a.a.

According to Mr. Le Cat, the *pia mater* gives three membranes to the eyes; the first lines the sclerotic coat, and is joined to it by the second to the choroid coat, and the third to the vitreous membranes one, proceeding from the choroid, and is commonly called *Morgagni's tunic*. Med. Ess. Edinb. Art. vol. ii. p. 382.

PIABA, in *Ichthyology*, the name of a small freshwater fish, caught in all the rivers and brooks in the Brasils, and some other parts of America.

It is of the size of the common minnow; is a well-tasted fish, and much esteemed by the natives.

TARUCU, in *Ichthyology*, the name of an American fish, esteemed by the natives in many places. It is a very large fish, and so greedy of blood, that if a man happens to be in the water with a wound in any part of his body, this fish will make at it to suck the blood: it is a small fish, seldom exceeding four inches in length.

TACHE, PYRAMIS reversed in the *Arms*, or POINTED and POINTLE.

TAFFUR, in the *Arms*, a point, barry of six pieces, being full of mettles, or fire, issuing out and forming a great deal of motion, and an excellent figure to engrave upon

wards, makes this motion the more that you endeavour to keep him in, and bends his leg up to his belly. He snorts, traverses if he can, and by his fiery action shows his restlessness; whence some, though very improperly, say, he dances.

Such horses as these, or such as are bred to passage upon a straight line, are much admired in carousals and magnificent festivals. See SHORT, and PASSADE.

PIANISSIMO, in the *Italian Music*, is used to signify that the part to which it is added should be played very softly, and so as that the sound may seem at a great distance, and almost lost in air. See Corelli Concerto viii. in fine.

PIANO, in the *Italian Music*, signifies soft and sweet, by way of an echo.

PIANO *forte*, is the name of a well known musical instrument, resembling the harpsichord.

PIANO PIANO, or PIU PIANO, in the *Italian Music*, is nearly the same with *pianissimo*, or rather a degree between it and *piano*.

PIANO, *pia*, in the *Italian Music*, signifies more slow, or more soft, and is much the same with *piano piano*.

PIASTER, a Spanish money, more ordinarily called a PIECE *of eight*.

PIAZZA, in *Building*, popularly called *piache*, an Italian name for a portico, or covered walk, supported by arches. The word literally signifies a broad open place, or square; whence it also became applied to the walks, or porticoes around them.

PIC, an East Indian weight, containing one hundred CATTY.

PICA, or PYE, was a term formerly used in the same sense with ORDINAL, for a table or directory, pointing out the order in which the devotional services appointed for different occasions were to be performed. Accordingly some derive it from It. a contraction of *mat*, *a table*; and others from *littera picata*, a great black letter at the beginning of some new order in the prayer. In much the same sense the term was used by officers of civil courts, who called their calendars or alphabetical catalogues directing to the names and things contained in the rolls and records of their courts the *Pyes*.

PICA, in *Medicine*, *malacia*, or a depravation of appetite; which makes the patient absurdly covet things unfit for food, or incapable of nourishing, as coals, ashes, plaister, salt, lime, chalk, vinegar, pepper, &c.

The *pica* is frequent in girls, and in women with child; men are more rarely affected with it. The disorder is seldom original, but is usually an effect of an hypochondriacal infirmity in men; and of a chlorosis, stoppage of the menses, or their eruption about the second month of pregnancy in women: sometimes it seems to be hereditary in children, from some cause affecting the mother. The disease is usually supposed to have its rise from a vicious ferment of the stomach; to which may be added, also, some disorders of the imagination, occasioned by ill examples, and ridiculous prejudices.

The usual remedies in the *pica* are bleeding, purging, vomiting, and chalybeats.

PICA, in *Ornithology*. See MAGPYE.

PICA is also a name by which some have called the *lanius*, or BUTCHER *bird*.

PICA, in *Printing*. See PRINTING.

PICA *marina*, in *Ornithology*, the name of a bird called in English the *sea pie*, and by Bellonius and some others, the HÆMATOPUS. It is of the size of the common *magpye*; its beak is three fingers breadth long, strait, and of a reddish, or a blackish colour, and ending in a point, and seeming well fitted for its business of rooting up the limpets from the rocks, the bodies of this fish being its common food; its legs are red; it has no hinder toe, and has its other toes so far connected by a membrance, as to seem almost of a middle nature between the web-footed and other birds; its head, neck, back, throat, and half its breast are black, as is also its rump; its tail is half black, and half white, as are also its wings. It is common on the western shores of England, and on the shores of Wales.

PICA *marina* is also used by Gesner very improperly for the bird commonly known by the name of *anas arctica Clusii*. See PUFFIN.

PICA *nasi*, in *Medicine*, a name given by Cohausen to the immoderate taking of snuff. It seems a whimsical term, but he chuses to treat this habit as a disease, and has written an express treatise concerning it. The word *pica*, in general, denotes an absurd and unnatural appetite; and the desire of taking the powder of tobacco in this manner is called a distempered appetite of the part into which it is taken, that is, the nose.

The consequences of the taking snuff immoderately, are, that the sense of smelling is either entirely destroyed, or at least greatly impaired: for the nervous tubercles of the nostrils being continually vellicated by this powder, are by degrees clogged up, or wholly destroyed, and the sensible membrane, which lines the nostrils, is rendered callous, and wholly unfit for the discharge of its office in smelling. The voice is next affected by this powder; for it causes a sort of astriction at the bottom of the nose, which affects the palate, and consequently the speech; this gives the person who takes it a continual desire of taking more and more, to rid himself of that stoppage.

PICACIA, a name given by the ancients to that distempered appetite of women with child, and maidens at a certain time of life, which makes them long for things not fit for food. It is more usually called PICA.

PICACUROBA, in *Ornithology*, the name of a Brasilian species of pigeon, of a greyish colour variegated with a reddish brown, and with very red legs and feet.

PICÆ, *pies*, in the Linnæan system of *Ornithology*, is the name of one whole order of birds; the general character of which is, that they have a convex beak, flatted above. To this order belong twenty-two genera, and two hundred and forty-three species. See PARROT, TOUCAN, CROW, *Bird of* PARADISE, ORIOLE, CUCKOW, KING'S-FISHER, HOOPOE, CREEPER, &c.

PICARD, in our *Old Writers*, a kind of large boat, about fifteen tons or upwards, used on the river Severn. Stat. 35 Hen. VIII. *cap.* 9. 13 Eliz. *cap.* 11.

PICARDS, a religious sect, who arose in Bohemia in the fifteenth century; so called from their author, who, because he originally came from Picardy, was called *Picard*. He drew after him, as it has been very unjustly said, a great number of men and women, pretending he would restore them to the primitive state of innocence wherein Adam was created: and accordingly himself assumed the title of the New Adam.

Under this pretence he taught his followers to abandon themselves to all impurity; making them believe, that therein consisted the liberty of the sons of God; and that all those not of their sect were in bondage.

He first began in Germany, and the Low Countries, persuading many people to go naked, and giving them the name of ADAMITES. After this, seizing an island in the river Lausnez, a few leagues from Thabor, the head quarters of Ziska, he fixed himself and his followers therein; appointing his women to be common, but allowed none to enjoy them without his permission: so that when any man desired a woman, he carried her to *Picard*, who gave him leave in these words, *Go, increase, multiply, and fill the earth.*

At length, Ziska, the great general of the Hussites, (so famous for his victories over the emperor Sigismund), struck with their abominations, marched against them; and, making himself master of their island, put them all to death except two; whom he spared to inform himself of their doctrine.

Such is the very false and injurious account, which different writers, ultimately relying on the insufficient authorities of Æneas Sylvius, and Varillas, have given of the *Picards*, who seem to have been a party of the VAUDOIS, that fled from persecution in their own country, and sought refuge, about the beginning of the fifteenth century, in Bohemia. It is very doubtful, whether a sect of this denomination, chargeable with the licentious principles and conduct above recited, ever existed; and we cannot forbear expressing our astonishment that Mr. Bayle, in his art. *Picards*, should adopt the reproachful representations of the writers just mentioned.

It is most probable, that the whole is a calumny invented and propagated, in order to disgrace the *Picards*, because they deserted the communion and protested against the errors of the church of Rome. Lasitius relates, that *Picard* settled in Bohemia, in the year 1418, accompanied by forty other persons, besides women and children. The Jesuit Balbinus, in his Epitome Rerum Bohemicarum, lib. ii. concurs in this account, and charges on the *Picards* none of the extravagances or crimes ascribed to them by Sylvius. Schlecta, secretary of Ladislaus, king of Bohemia, in his letters to Erasmus, gives a particular account of the *Picards*; representing them as persons, who considered the pope, cardinals, and bishops of Rome, as the true Antichrists; who censured those that adored the consecrated elements in the eucharist, as idolaters, and denied the corporal presence of Christ. In this ordinance; who condemned the worship of saints, prayers for the dead, auricular confession, the penance imposed by priests, the feasts and vigils observed in the Romish church; and confined themselves to the observance of the sabbath, and of the two great feasts of Christmas and Pentecost. From this abstract of their sentiments, it sufficiently appears, that they were no other than the VAUDOIS; and M. de Beausobre has plainly shewn, that they were both of the same sect under different denominations. Besides, it is a certain fact, that the Vaudois were settled in Bohemia, in the year 1178, where some of them adopted the rites of the Greek church, and

others those of the Latin church. The former were generally adhered to till about the middle of the fourteenth century, when the establishment of the Latin rites occasioned great disturbance. When the national troubles commenced in Bohemia, on occasion of the opposition to the papal power (see MORAVIANS), the *Picards* appeared more publicly in the avowal and defence of their religious opinions, and they formed a considerable body in an island by the river Lusnitz or Lausnetz, in the district of Bechin, and recurring to arms, were defeated by Ziska. Encyclop. art. *Picards*.

PICATUM *vinum*. See VINUM.

PICICILLI, in *Ornithology*, the name of a bird in the Spanish West Indies, described by Nieremberg. Its head and neck are black, and its whole body grey; it is a small bird, and makes its appearance in Mexico after the rainy seasons; it is a bird of paſſage, and it is not known where it breeds.

PICK, among *Miners*, is a tool with which they uſe to cut down the clifts and rocks of ſtone to make paſſages in the earth.

PICK-*axe*, in the *Military Art*, a tool carried by the pioneers to dig up ground that is too hard for the ſpade; they are of great uſe for mending the ways, and in fortification.

PICKS, *ear*. See EAR-*picks*.

PICKAGE, or PICCAGE, *piccagium*, an ancient cuſtom, or duty, paid at fairs and markets, for breaking the ground, and pitching up ſtalls, or ſtandings.

This profit of *pickage* was uſually given, or granted, in charters for holding a fair or market.

PICKEERING, or PICKEROONING. See PICQUEERING.

PICKER, or *horſe*-PICKER, in the *Manage*, an iron inſtrument five or ſix inches long, bent or crooked on one ſide, and flat and pointed on the other. It is uſed by grooms to cleanſe the inſide of the horſes feet, and to pick out the earth, ſand, or ſmall ſtones that get into them.

PICKERELL, in *Ichthyology*, an Engliſh name uſed by ſome authors for the JACK or PIKE.

PICKET, PICQUET, or PIQUET, in *Fortification*, a ſtake ſharp at one end, and uſually ſhod with iron; uſed in laying out the ground, to mark the ſeveral meaſures and angles thereof.

There are alſo larger *pickets*, driven into the earth to hold together faſcines, or faggots, in any work caſt up in haſte.

PICKETS are alſo ſtakes driven into the ground by the tents of the horſe, in a camp, to tie their horſes to; and before the tents of the foot, where they reſt their muſkets, or pikes about them, in a ring.

When a horſeman hath committed any conſiderable offence, he is often ſentenced to ſtand on the *picket*; which is to have one hand drawn up as high as it can be ſtretched, and thus to ſtand on the point of a *picket*, or ſtake, only with his oppoſite foot: ſo that he can neither ſtand nor lean well, nor eaſe himſelf by changing feet.

PICKETS are alſo ſtakes with notches toward the top, to which are faſtened the cordages of tents. Thus, to plant the *pickets*, is to encamp.

PICKET, in *Gaming*. See PICQUET.

PICKLE, a brine, or liquor, ordinarily compoſed of ſalt, vinegar, &c. ſometimes with the addition of ſpices; wherein meats, fruits, and other things, are preſerved and ſeaſoned.

PICKLE is alſo uſed ſubſtantively, for a fruit, root, leaf, or other vegetable matter, prepared *in pickle*, to be uſed by way of ſauce, &c. See SALLET, &c.

They *pickle* artichokes, muſhrooms, athen-keys, barberries, aſparagus, beans, &c. Broom-buds, capers, and olives, are pickled with oil and vinegar.

PICKLED *fiſh*. See FISH.

PICLE, (*piſtillum*), a ſmall parcel of land incloſed with a hedge; a little cloſe. This word ſeems to come from the Italian *piccolo*, i. e. *parvus*; and in ſome parts of England is called *pightel*.

PICOLOS, the name of an ancient Pruſſian idol, to which human ſacrifice was offered. See POTRIMPOS.

PICOTA, a name given by ſome authors to a diſtemper which they deſcribe as conſiſting wholly in an eruption of a number of very minute pimples upon the ſkin, all over the body; it is attended with no danger, unleſs they are ſtruck in.

PICQUEERING, PICKEERING, or PICKEROONING, a little flying war or ſkirmiſh, which the ſoldiers make when detached from their bodies to pillage, or before a main battle begins.

PICQUET, or PICKET, a celebrated game at cards, much in uſe throughout the polite world.

It is played between two perſons, with only thirty-two cards; all the duces, threes, fours, fives, and ſixes, being ſet aſide.

In reckoning, at this game, every card goes for the number it bears, as a ten for ten; only all court-cards go for ten, and the ace for eleven: and the uſual game is one hundred up. In playing, the ace wins the king, the king the queen, and ſo down. Twelve cards are dealt to each, uſually by two and two; which done, the remainder are laid in the middle. If one of the gameſters finds he has not a court card in his hand, he is to declare he has *carte blanche*, and tell how many cards he will lay out, and deſire the other to diſcard, that he may ſhew his game, and ſatisfy his antagoniſt, that the *carte blanche* is real; for which he reckons ten.

Each perſon *diſcards*, i. e. lays aſide a certain number of his cards, and takes in a like number from the ſtock. The firſt, of the eight cards, may take three, four, or five; the dealer all the remainder, if he pleaſes.

After diſcarding, the eldeſt hand examines what ſuit he has moſt cards of; and, reckoning how many points he has in that ſuit, if the other have not ſo many in that, or any other ſuit, he tells one for every ten of that ſuit. He who thus reckons moſt is ſaid to win the *point*.

The point being over, each examines what *ſequences* he has of the ſame ſuit; viz. how many tierce, or ſequences of three; quarte, or fours; quintes, or fives; ſixiemes, or ſixes, &c. For a tierce they reckon three points, for a quarte four, for a quinte fifteen, and for a ſixieme ſixteen, &c. And the ſeveral ſequences are diſtinguiſhed in dignity by the cards they begin from: thus ace, king, and queen, are called *tierce major*; king, queen, and knave, *tierce to a king*; knave, ten, and nine, *tierce to a knave*, &c. and the beſt tierce, quarte, or quinte, i. e. that which takes its deſcent from the beſt card, prevails; ſo as to make all the others in that hand good, and deſtroy all thoſe in the other hand. In like manner, a quarte in one hand ſets aſide a tierce in the other.

The ſequences over, they proceed to examine how many aces, kings, queens, knaves, and tens, each holds; reckoning for every three, of any ſort, three; but here too, as in ſequences, he that with the ſame number of threes has one that is higher than any the other has, e. g. three aces, has all his other made good hereby, and his adverſary's are all ſet aſide. But four of any ſort, which is called a *quatorze*, always ſet aſide three.

All the game in hand being thus reckoned, the eldeſt proceeds to play, reckoning one for every card he plays above a nine, and the other follows him in the ſuit: and the higheſt card of the ſuit wins the trick. Note, unleſs a trick be won with a card above a nine (except the laſt trick), nothing is reckoned for it; though the trick ſerves afterwards towards winning the cards; and that he who plays laſt does not reckon for his cards, unleſs he win the trick.

The cards being played out, he that has moſt tricks reckons ten for *winning the cards*. If they have tricks alike, neither reckons any thing. The deal being finiſhed, and each having marked up his game, they proceed to deal again as before; cutting afreſh each time for the deal.

If both parties be within a few points of being up, the carte blanche is the firſt thing that reckons; then the point, then the ſequences, then the quatorzes or threes, then the tenth cards.

He that can reckon thirty in hand by carte blanche, points, quintes, &c. without playing, before the other has reckoned any thing, reckons ninety for them; and this is called a *re-pique*. If he reckons above thirty, he reckons ſo many above ninety. If he can make up thirty, part in hand, and part play, before the other has told any thing, he reckons for them ſixty. And this is called a *pique*. Whence the name of the game.

He that wins all the tricks inſtead of ten, which is his right, for winning the cards, reckons forty; and this is called a *capot*.

This game has in ſome caſes been the object of mathematical computations.

Thus Mr. *de* Moivre has propoſed and ſolved the following problems:

1. To find at *picquet* the probability which the dealer has for taking one ace or more in three cards, he having none in his hand. He concludes from his computation, that it is 29 to 28 that the dealer takes one ace or more.

2. To find at *picquet* the probability which the eldeſt has of taking an ace or more in five cards, he having no ace in his hand. Anſwer; 232 to 91, or 5 to 2, nearly.

3. To find at *picquet* the probability which the eldeſt hand has of taking an ace and a king in five cards, he having none in his hand. Anſwer; the odds againſt the eldeſt hand taking an ace and a king are 33 to 16, or 21 to 10 nearly.

4. To find at *picquet* the probability of having two cards dealt to, without king, queen or knave. Which caſe is commonly called *cartes blanches*. Anſwer; the odds againſt *cartes blanches* are [illegible]

5. To find how many different [illegible] from one another, one may have [illegible]

in. Anſwer; 28,967,278. This number falls ſhort of the ſum of all the diſtinct combinations, whereby twelve cards may be taken out of 32, this number being 225,792,840; but it ought to be conſidered, that its that number ſeveral ſets of the ſame import, but differing in ſuit, might be taken, which would not introduce an eſſential difference among the ſets.

Mr. de Moivre alſo gives ſome obſervations on this game which he had from an experienced player. See Doctrine of Chances, p. 179, &c.

M. de Monmort has alſo treated of *piquet* in his Analyſe des jeux de Hazard, p. 162.

PIQUET *guard*. See GUARD.

PICRA, *bitter*. See HIERA.

PICRIS, in *Botany*, the name given by Linnæus to a genus of plants, of the *ſyngeneſia polygamia æqualis* claſs, called by Vaillant *helminthoca*; the characters of which are theſe: the common cup is double; the outer cup is very large, and compoſed of five cordated leaves; the interior is imbricated and of an oval figure, and is not cloſe at the mouth, as the other, but open; the flower is of the compound kind, it is imbricated and uniform; and the ſmall flowers of which it is compoſed are equal and numerous; each is compoſed of one petal, and is narrow, ligulated and truncated at the end, where it is divided into five ſegments; the ſtamina are five capillary filaments, ſo ſhort that they are hardly ſeen; the antheræ are cylindric and tubulate; the germen of the piſtil ſtands under the flower; the ſtyle is of the length of the ſtamina, and the ſtigmata are two in number, and reflex; the cups both remain when the flowers are fallen, and ſerve as capſules for the ſeeds, which are ſingle, ventricoſe, obtuſe, and crowned with a plume or down; the receptacle is naked. There are three ſpecies.

In ſome of the ſpecies of this genus, the ſeeds are crooked, and have a ſeſſile down; in others they are ſtraight, and their down is placed on a pedicle.

PICTA *toga*. See TOGA.

PICTS *wall*, in *Antiquity*, a famed piece of Roman work, begun by the emperor Adrian, A. D. 124, on the northern bounds of England, to prevent the incurſions of the Picts and Scots.

At firſt it was made only of turf, ſtrengthened with paliſadoes, till the emperor Severus, coming in perſon into Britain, repaired it, as ſome ſay, with ſolid ſtone, reaching eighty miles in length, from the Iriſh to the German ſea, through Carliſle and Newcaſtle; with watch-towers garriſoned, now called caſtle-ſteeds, at the diſtance of a mile from each other.

It does not appear, with ſufficient evidence, that Severus's wall was formed of ſtone: Bede expreſly aſſerts the contrary, though Spartian intimates that Severus built both a *murus*, i. e. a wall of ſtone, and a *vallum*, or a wall of turf. Bede's words are theſe: Severus, after ſeveral great and difficult engagements, thought it neceſſary to ſeparate that part of the iſland which he had recovered, from the other nations that were unconquered; not with a *murus*, as ſome think, but with a *vallum*: now a *murus*, ſays he, is of ſtone; but a *vallum*, ſuch as they made round a camp to ſecure it againſt the attacks of the enemy, is made of turf cut regularly out of the ground, and built high above ground like a wall, with the ditch before it, out of which the turf has been dug; and ſtrong ſtakes of wood all along the brink. Severus, therefore, drew a great ditch, and built a ſtrong earthen wall, fortified with ſeveral turrets from ſea to ſea. The learned Camden adopts this opinion; and adds, that Severus's wall is expreſſed by no other word than *vallum*, either in Antoninus or the Notitia. Camd. Brit. vol. ii. p. 1045. See AGGER.

This wall was ruined ſeveral times by the *Picts*, and often repaired by the Romans. At laſt Attius, a Roman general, ordered it to be rebuilt of ſtone, about the year 420; but the *Picts* ruining it in the year following, it was no longer regarded but as a boundary between the two nations.

The wall was eight feet thick, and twelve high from the ground: it ran on the north ſide of the rivers Tyne and Iſthing, up and down ſeveral hills: the tract, or remains, of it, are to be ſeen to this day in many places both in Cumberland and Northumberland.

The inhabitants of the country pretend, that there was a brazen trumpet or pipe, ſo artificially laid in the wall between each caſtle and tower, that upon the apprehenſion of danger at any one place, by the ſounding of it, notice might be given to the next, and then to the third, &c. whence it derives the ancient name CORNAGE; and in the inſide a ſort of fortified little town, now called Cheſter, the foundations of which appear, in ſome places, in a ſquare form.

PICTAVENSIS, or PICTONUM *calica*, the name of a kind of very terrible nervous colic, more uſually called *colica pictonum*; and by the natives in the Weſt Indies, where it rages, the *dry belly-ach*. It is ſo popular a diſeaſe in the Leeward Iſlands, that it may be very juſtly reckoned endemic among them, moſt of the people there having been at one time or other ſubject to it in all its fury. See COLICA *Dammoniacum*.

PICTURE, *pictura*, a piece of painting, or a ſubject repreſented in colours, on canvas, wood, or the like; and incloſed in a frame.

Pictures or paintings in oil are preſerved by coating them with ſome tranſparent and hard ſubſtance, as a varniſh, in order to ſecure the colours from the injuries of the air or moiſture; and to defend the ſurface from ſcratches or any damages the painting might receive from ſlight violence. The ſubſtances, that have been, or may be uſed for this purpoſe, are gum arabic, diſſolved in water with the addition of ſugar or ſugar-candy, to prevent its cracking, glair or whites of eggs, mixed with a little brandy or ſpirit of wine in order to make it work more freely, and a lump of ſugar to prevent its cracking, iſinglaſs-ſize uſed as either of the former, or mixed with a fourth or fifth of its weight of honey or ſugar, and varniſhes formed of gum reſins diſſolved in ſpirit of wine, or oil of turpentine, which laſt are called *oil-*VARNISHES.

Paintings in miniature are preſerved by plates of glaſs or the talc called iſinglaſs placed before them in the frame. Paintings in diſtemper may be rendered more durable, and preſerved from ſoulneſs by varniſhing them with hot ſize, boiled to a ſtrong conſiſtence, in which a fifteenth or twentieth part of honey has been diſſolved. Crayons muſt be preſerved in the ſame manner with paintings in water colours, by plates of glaſs, or iſinglaſs.

When *pictures* are cut or torn, they may be repaired by laying them on an even board or table, carefully putting together the torn or diſided parts with ſome of the matter of the SMOUT-*pot* laid as a cement, in and over the joint, and keeping them in the ſame ſituation till the cement is thoroughly dried. The protuberance of the cement may be eaſily reduced with a penknife, and the repaired part properly coloured ſo as to correſpond with the *picture*. When part of the cloth is deſtroyed, a piece of canvas ſomewhat bigger than the vacant ſpace is to be plaiſtered over on the outſide of the cloth with the matter of the ſmouth-*pot*, and when it is thoroughly dry, the inequality of the *picture* in this part is to be filled up with the ſame matter, and properly reduced and coloured.

The art of cleaning *pictures* and paintings is of great conſequence in order to their preſervation: in this operation great ſkill and care are requiſite, ſo that the menſtruum uſed for taking off any foulneſs may not diſſolve the oil in the painting itſelf or diſorder its colours, and that each ſort of varniſh with which paintings are covered may be taken off without injury to the painting. The firſt and moſt general ſubſtance uſed for cleaning *pictures* is water, which will remove any foulneſs ariſing from many kinds of glutinous bodies, as ſugar, honey, glue, &c. and any varniſh of gum arabic, glair of eggs or iſinglaſs, without affecting the oil which holds the colours together. Olive oil or butter will diſſolve pitch, reſin, and other ſubſtances of a like kind, without injuring the oil of the painting. Pearl aſhes, diſſolved in water, form a proper menſtruum for moſt kinds of matter that foul paintings: but they muſt be very cautiouſly uſed, as they will corrode the oil of the painting, if there be no varniſh of the gum reſins over it. Soap is of the ſame nature, and ſhould be cautiouſly applied, and only to particular ſpots, that elude all other methods. Spirit of wine will diſſolve all the gums and gum reſins, except gum arabic, and is therefore very neceſſary for taking off from *pictures*, varniſhes compoſed of ſuch ſubſtances. but it alſo corrodes the oil of the painting. This is alſo the caſe with oil of turpentine, and eſſence of lemon, ſpirit of lavender, and roſe-mary, and other eſſential oils. With regard to paintings that are varniſhed with gum arabic, glair of eggs, or iſinglaſs, the varniſh ſhould be taken off when they are to be cleaned. This may be eaſily diſtinguiſhed by wetting any part of the painting, which will feel clammy, if varniſhed with any ſubſtance ſoluble in water. This kind of varniſh may be taken off with hot water and a ſponge, or by gentle rubbing with a linen cloth dipped in warm water. If paintings, on this trial, appear to be varniſhed with the gum-reſins, or ſuch ſubſtances as cannot be diſſolved in water, they may, in ſome caſes, be ſufficiently cleaned by a ſponge with warm water; and any remaining foulneſs may be removed by rubbing the painting over with olive oil made warm, or with butter, which ſhould be wiped off with a woollen cloth; and if the *picture* require farther cleaning, wood-aſhes or pearl-aſhes may be uſed in the following manner: take an ounce of pearl-aſhes, and diſſolve them in a pint of water; or take two pounds of wood aſhes, and ſtir them well in three quarts of water, once or twice in an hour for half a day. Then pour off the clear fluid,

and

and evaporate it to a quart or three pints: wash the painting well with a ſponge dipped in either of theſe leys, and rub gently any foul ſpots with a linen cloth till they diſappear. If this method fail, recourſe muſt be had firſt to ſpirit of wine, then to oil of turpentine, and if theſe are ineffectual, the eſſence of lemons; with either of which the foul ſpots ſhould be ſlightly moiſtened, and the part immediately rubbed gently with a linen cloth. After a little rubbing, if oil of turpentine or eſſence of lemons has been applied, olive oil ſhould be put upon the ſpot; and water, if ſpirit of wine has been uſed; which ſhould be taken off with a woollen cloth; repeating the operation till the foulneſs be removed. When paintings appear to have been varniſhed with thoſe ſubſtances that will not diſſolve in water, and after the uſe of the above means retain their foulneſs, the following method will ſucceed: place the *picture* or painting in a horizontal ſituation; and moiſten, or rather bood, by means of a ſponge, the ſurface with very ſtrong rectified ſpirit of wine: keep the painting thus moiſtened, by adding freſh quantities of the ſpirit, for ſome minutes; then flood the whole ſurface copiouſly with cold water; waſh off the whole without rubbing; and when the painting is dry, repeat the operation, till the whole varniſh is taken off. Handm. to the Arts, vol. i. p. 224. 245.

PICTURES, *method of taking off decayed.* See PAINTING.

PICTURE, *magical.* See MAGICAL.

PICUIPINIMA, in *Ornithology*, the name of a Braſilian ſpecies of pigeon, very ſmall, ſcarce exceeding the lark in ſize. Its head, neck, and wings, are all of a pale-lead colour, with a black ſemilunar mark at the extremity of each wing; but its long wing-feathers, which are ſeen when the wings are expanded in flying, are of a reddiſh-brown on one ſide, and blackiſh on the other, with black ends or tips; the tail is long, and is variegated with black, white, and brown; the belly is covered with white feathers, every one of which has a brown mark of the ſhape of a half moon at the end.

PICUS, or PICUS *martius*, in *Ornithology*, the name of a large genus of birds, of the wood-pecker kind, the characters of which are theſe: they have a ſtraight, very hard, ſtrong, and ſharp beak, proper for making holes in trees; and a very long cylindrical-ſhaped tongue, terminated by a rigid and ſharp bony ſpine, ſerrated or notched at each end, proper for the ſeizing on, and tearing to pieces, of worms and other inſects; and this they can, at pleaſure, thruſt out to a great length; and ſtriking it into the clefts of trees, faſten it into inſects that lie there, and draw them out with it; their thighs are very ſhort and ſtrong, and their toes four in number, placed two before and two behind; their tails are rigid, and bent downwards, and their feathers bare at the ends, the ſtumps aſſiſting the creature in climbing: they live only on inſects, and have only ten feathers in their tail. Ray. The *picus martius* in the Linnæan ſyſtem is a ſpecies of the PICUS.

Some underſtand the word *picus* in a larger ſenſe, making it take in the *fitta*, *picus muravius*, *junx*, *certhia*, and all the birds that climb trees. In which caſe the characters of the genus are only, that they have very ſhort, thick, and ſtrong legs, adapted to the running up the bodies and branches of trees.

The *pici*, or wood-peckers, properly ſo called, however, are a very large and numerous family.

In the Linnæan ſyſtem of Ornithology, the *picus* makes a diſtinct genus of birds of the order of the pyes. The character of this genus, according to this author, are, that the bill is ſtraight and angular, and terminates in the form of a wedge; the noſtrils are covered with briſtly feathers reflected down; the tongue is long, cylindric, formed for ſeizing worms, ſharp-pointed, and jagged; the feet are formed for climbing. See PICUS above. Linnæus enumerates twenty-one ſpecies.

Of this genus are the black, green, and variegated wood-pecker, and the three-toed ſpecies, deſcribed in the Acta Literaria Suecia, in 1740. See WOOD-*Picker*.

PICUS *imbrifarius*, or *picus principalis* of Linnæus, in *Ornithology*, the name of an American bird, deſcribed by Nieremberg, and called by the natives QUATOTOMIMI. It is of the ſize of the hoopoe, and is variegated with black and brown; it is of the wood-pecker kind, having a beak three fingers breadth long, with which it perforates trees; its head is ſmall and red, and has a fine red creſt; but the feathers are black on their upper ſide; it has on each ſide of the neck a broad white line, reaching to the breaſt; its legs and feet are of a bluiſh colour; it builds in high trees, and is principally found near the ſhores of the South Sea. It feeds on inſects. See IPECU.

PICUS *murarius*, in *Ornithology*, the name of a bird called in Engliſh the *wall-creeper*, and improperly ranked among the *pici*, as wanting many of the characters of that genus: and therefore claſſed in the Linnæan ſyſtem under the genus of CERTHIA, or CREEPER, which beſides this, comprehends alſo twenty-four other ſpecies. It is about the bigneſs of the common ſparrow; its bill is black, ſlender, and long; its head, neck, and back grey; its breaſt white, and its wings partly grey and partly red; its tail is ſhort and black; its long wing-feathers alſo, and the lower part of its belly, and its legs, are of the ſame colour; its legs are ſhort, but its feet are not placed as in the wood-pecker; but are three before and one behind: it is very common in Italy, Germany, and ſome parts of France; it is a very lively and chearful bird, and as the common wood-pecker climbs trees and feeds on the inſects in their cracks, ſo this bird runs up old walls, and feeds on what it finds in the cracks of the ſtones.

PICUS *nidum ſuſpendens*, a name by which ſome authors have called the GALBULA; a yellow bird of the thruſh kind, very remarkable for its beauty, and for the ſtructure and manner of hanging its neſt.

PICUS *ſalutiferus*, in *Ornithology*, the name under which Nieremberg has deſcribed a Mexican bird, called by the natives *hanguecholtzotli*.

It is of the ſize of the common black-bird, and has a long and black beak: its head and a great part of its neck are red; its breaſt and belly are grey, and it has a creſt of red feathers upon its head: it is of the wood-pecker kind, and has its name from the ſuppoſed virtues of its feathers, particularly thoſe of the creſt, in curing the head-ach.

PIECE, in *Commerce*, ſignifies ſometimes a whole, and ſometimes only a part of the whole.

In the firſt ſenſe we ſay, a *piece* of cloth, of velvet, &c. meaning a certain quantity of yards, regulated by cuſtom, being yet entire, and not cut.

In the other ſignification we ſay, a *piece* of tapeſtry; meaning a diſtinct member wrought apart, which, with ſeveral others, make one hanging.

A *piece* of wine, of cyder, &c. is a caſk full of thoſe liquors.

PIECE, *chimney.* See CHIMNEY.

PIECE, *detached.* See DETACHED.

PIECE, *eaſel.* See EASEL.

PIECE, *maſter.* See MASTER.

PIECE, in *Matters of Money*, ſignifies ſometimes the ſame thing with *ſpecies*: as when we ſay, this *piece* is too light, &c.

Sometimes, by adding the value of the *piece*, it is uſed to expreſs ſuch as have no other particular name: as a *piece* of eight rials, a *piece* of twenty-five ſols, &c.

In England, the *piece*, abſolutely, is ſometimes uſed for twenty ſhillings ſterling, and ſometimes for a guinea.

By 6 Geo. II. cap. 25. *broad-pieces*, of five-and-twenty, or three-and-twenty ſhillings value, or any halves or quarters thereof, are called in. And all perſons are forbid to receive or utter them in payment by tale.

PIECE *of eight*, or *piaſtre*, is a ſilver money, firſt ſtruck in Spain, afterwards in other countries, and now current in moſt parts of the world.

It has its name *piece of eight*, or *rial of eight*, becauſe equal to eight ſilver rials.

Its value is nearly on the ſame foot with the late French crown, viz. four ſhillings and ſix pence ſterling. In 1687, the proportion of the ſimple rial to the piaſtre was changed; and in lieu of eight rials they gave ten. At preſent the reduction is on the ancient ſtandard.

There are two kinds of piaſtres, or Spaniſh crowns; the one ſtruck at Potoſi, the other at Mexico: theſe latter are a little heavier than the former; but, in return, they are not quite ſo fine.

The *piece of eight* has its diminutions; viz. the demi-piaſtre, or *piece of four rials*; the quarter, or *piece of two*; the half-quarter, and the ſixteenth. The EXCHANGE between Spain and England is made in *pieces of eight*. See COIN.

PIECE is alſo a kind of money of account, or rather a manner of accounting, uſed among the negroes on the coaſt of Angola, in Africa.

The price of ſlaves, and other commodities here negotiated, as alſo the duties paid the petty Kings, are eſtimated on both ſides in *pieces*. Thus thoſe barbarians requiring ten *pieces* for a ſlave, the Europeans in like manner, value the money, or merchandize, to be given in exchange, in *pieces*.

PIECE, in *Heraldry*, denotes an ORDINARY, or CHARGE.

PIECES, in the *Military Art*, include all ſorts of great guns and mortars.

Theſe are alſo called *pieces of* [illegible] or *artillery*.

PIECES, *field.* See FIELD-*pieces*.

PIECES, *battery.* See *Great* GUNS.

PIECES, *garriſon.* See GARRISON.

PIECE, *poiſoning a.* See POISONING.

PIECE, *ſoldier's.* See FIRELOCK.

PIECE, *elevation of a.* See ELEVATION.

PIECE, *quadrating to*. See QUADRATING.

PIEDOUCHE, *French*, formed from the Italian *piedestal*, *foot*, in *Architecture*, a little ſtand, or pedeſtal, either oblong or ſquare, enriched with mouldings; ſerving to ſupport a buſt, or other little figure. This is called a bracket pedeſtal.

PIEDRA *de la hyada*, in *Natural Hiſtory*, the name given by the Spaniards to a ſtone found in many parts of America, particularly in New Spain; and famous among the Indians for curing the colic on being applied to the navel. It is green, and is a ſpecies of jaſper, approaching to the nature of the *lapis nephriticus*, and is called by many *ſcitum lapis*, from its virtues.

PIEDROIT, in *Architecture*, a pier, or a ſquare kind of pillar, part whereof is bid within a wall.

The only thing wherein it differs from a PILASTER is that the latter has a regular baſe and capital, which the other wants.

PIEDROIT is alſo uſed for a part of the ſolid wall annexed to a door or window; comprehending the door-poſt, chamfrain, fabian, jeſt, &c.

PIE-POUDER, *curt.* See COURT.

PIER, in *Building*, derived from the French *pierre*, a *ſtone*, denotes a maſs of ſtone, &c. oppoſed, by way of fortreſs, againſt the force of the ſea, or a great river, for the ſecurity of ſhips that lie at harbour in any haven. Such are the *pier* of Dover, deſcribed by Camden Brit. &c. the *pier* of Hamſgate, and the haven *pier* of Great Yarmouth, maintained 22 Car. II.

PIERS are alſo uſed in *Architecture* for a kind of *pilaſters*, or buttreſſes, raiſed for ſupport, ſtrength, and ſometimes for ornament.

PIERS, *circular*, are called *engaged* COLUMNS, and they are with or without caps, and are frequently ſeen in Gothic architecture.

PIERS *of a bridge*. See BRIDGE.

M. Belidor obſerves that, when the height of the *piers* is about ſix feet, and the arches are circular, it is ſufficient to make their thickneſs the ſixth part of the width of the arch, and two feet more; but when the arches become of a great ſpan, the thickneſs of the *piers* may be reduced to the ſixth part; but then the depreſſion of the two feet doth not take place at once; that is, in an arch of above forty-eight feet, three inches are taken off for every ſix feet of increaſe of the width of the arch. The thickneſs of the *piers* ſupporting elliptic arches is greater than in the former proportion; thus, in an arch of ſeventy-five feet wide, the thickneſs of the *piers*, whoſe height is about ſix feet, ſhould be 15.5 when the arch is circular, and fifteen feet when it is elliptical.

The ſame author makes the *abutments* one-ſixth part more than the *piers* of the ſame arch.

Mr. Muller has calculated the following TABLE, containing the thickneſs of the *piers* of bridges.

TABLE, containing the thickneſs of the *piers of bridges*.

	6	9	12	15	18	21	24
20	4.574	4.918	5.265	5.550	5.892	6.236	6.580
25	5.120	5.465	6.215	6.555	6.645	6.880	7.593
30	6.186	6.526	7.225	7.613	7.46	7.615	8.102
35	7.235	7.80	8.20	8.552	8.807	9.057	9.533
40	8.404	8.665	9.234	9.623	9.955	10.10	10.588
45	9.65	9.918	10.20	10.600	37	11.1	11.591
50	10.87	11.254	11.586	12.0	12.31	12.17	13.13
55	12.00	12.25	12.602	12.964	13.579	13.140	13.418
60	13.10	13.45	13.81	14.18	13.782	14.09	14.384
65	14.26	14.62	15.01	15.40	15.80	15.054	16.233
70	15.42	15.809	16.209	16.609	17.013	16.414	16.410
75	16.60	17.00	17.350	17.808	18.260	16.04	17.354
80	17.80	18.22	18.634	19.047	19.461	19.874	18.198
85	19.00	19.198	19.60	19.64	20.157	20.748	19.19
90	20.21	20.628	21.039	21.478	21.157	20.779	20.452
95	21.42	21.85	22.272	22.438	22.20	22.06	21.06
100	22.64	23.08	23.52	23.80	24.08	23.46	23.976

The firſt horizontal line expreſſes the height of the *piers* in feet, from 6 to 24 feet, each increaſing by 3: the firſt vertical column, the width of arches from 20 to 100 feet, for every 5 feet.

The other columns expreſs the thickneſs of *piers* in feet and decimals, according to the reſpective height at the head of the *piers*, and the width of the arch againſt it in the firſt column.

Flying *piers* are ſeldom uſed but in bridges over ſmall rivers; in all others they project from the bridge by a triangular prism, which prefents an edge to the ſtream, in order to divide the water more eaſily, to prevent the ice from ſettering there, as well as veſſels from running foul againſt them; this edge is terminated by the adjacent ſurfaces at right angles to each other at *Weſtminſter* BRIDGE, but thoſe of the *Pont-royal*, at Paris, make an acute angle of about 60°. However the French, in their later conſtructions, make this angle to terminate by two cylindric ſurfaces, whoſe baſes are arcs of 60 degrees. Muller's Pract. Fortif. part 2. ſect. 1. p. 25, &c.

PIERCEA, the *iſlandica* of Tournefort, and RIVINIA of Linnæus, in *Botany*, is made a diſtinct genus by Miller. The characters are theſe: the flower has no petals; the empalement which incloſes the parts of generation, is compoſed of four oblong, oval, coloured leaves; it hath four ſtamina which ſtand erect and cloſe together, terminated by ſmall ſummits; in the center is ſituated a large roundiſh germen, ſupporting a ſhort ſtyle, crowned by an obtuſe ſtigma; the germen afterwards turns to a roundiſh berry, ſitting upon the reflexed empalement, having one cell, including a rough ſeed of the ſame form. There are two ſpecies. Theſe plants grow naturally in moſt of the iſlands in the Weſt Indies. The juice of the berries of the olant will ſtain paper and linen of a bright red colour, and many experiments made with it to colour flowers, have ſucceeded extremely well in the following manner: the juice of the berries was preſſed out, and mixed with common water, putting it into a phial, ſhaking it well together for ſome time, till the water was thoroughly tinged; then the flowers, which were white and juſt fully blown, were cut off, and their ſtalks placed into the phial; and in one night the flowers have been finely variegated with red; the flowers on which the experiments were made were the tuberoſe, and the double white narciſſus.

PIERCED, PIERCE', in *Heraldry*, is when an ordinary is perforated, or ſtruck through; ſowing, as it were, a hole in it.

This *piercing* is ſaid to be expreſſed in blaſon as to its ſhape: thus if a croſs have a ſquare hole, or perforation, in the centre, it is blaſoned, *four-pierced*, which is more proper than *quarter-pierced*, as Leigh expreſſes it; and accordingly the French call it *percé en croix*. When the hole, or perforation is round, it muſt be expreſſed *round-pierced*; which Gibbon in Latin calls *perforata*; becauſe all holes made with pierces, or augres, are round. If the hole in the centre be in the ſhape of a *lozenge*, it is expreſſed, *pierced lozenge-ways*.

All *piercings* muſt be of the colour of the field, becauſe *piercing* implies the ſhewing of what is under the ordinary, or bearing. And when ſuch figures appear on the centre of a croſs, &c. of another colour, the croſs is not to be ſuppoſed *pierced*, but that the figure on it is a charge, and muſt be accordingly blaſoned.

PIERCING, among *Farriers*, To *pierce a horſe's foot low*, is to pierce it too near the edge of the iron. To *pierce it fleſh*, is to pierce it in barbing.

PIERIDES, among the *Ancients*, an epithet given to the Muſes, upon account of their having been born in that part of the country of Macedon which was called *Pieria*.

PIERRE *d'automne*, a French name tranſlated from the Chineſe. It is the name of a medicinal ſtone, famous throughout the Eaſt, for curing all diſorders of the lungs. Many people ſuppoſe it had its name of the *autumn-ſtone*, from its being only to be made at that ſeaſon of the year; but it may be made equally at all times, and the origin of the name is to be further ſearched into.

The Chineſe chemiſts, like thoſe of all other nations, delight in a ſort of gibberiſh. A part of this is, the referring the ſeveral parts of the body to the ſeveral ſeaſons of the year. The lungs are in this ſcheme referred to autumn. Thus appears in their writings; and thus the ſtone for diſeaſes of the lungs came to be called *autumn-ſtone*.

It is a tedious preparation of human urine, and made as follows: they put thirty pints of the urine of a ſtrong and healthy young man into a large iron pot, and ſet it over a gentle fire; and when it is got to boil, they add to it, drop by drop, about a large tea-cup full of rape-oil: it is then left on the fire till the whole is evaporated to a thick ſubſtance reſembling black mud; they then take it out of the pot, and having it on a flat diſh, they dry it ſo that it may be powdered very fine.

This powder they moiſten with freſh oil, and put the maſs into a double crucible, ſurrounded with aſhes; where it ſtands till thoroughly dried again. They uſually powder this again, and putting it into a china veſſel, covered with ſilk cloth and 2 double papers, they pour on boiling water, which makes its way, drop by drop, through theſe coverings, till ſo much is got in as is ſufficient to reduce it to a paſte. This paſte is well mixed together in the veſſel it is kept in, and this is put into a veſſel of water, and the whole ſet over the fire. The matter thus becomes again dried in balneo Mariæ, and is then finiſhed. Obſerv. ſur les Cout. de l'Aſie, p. 328.

PIES, in our *Ancient Law-Books*. *Vide* PIE, were a

sort of monks, so called because they were black and white garments, like magpies; the same, we suppose, with those since called *Carmelites*: who, for a like reason, were anciently called by the French *Freres Barrez*.

They are mentioned by Walsingham, p. 174. *In quodam vetere cœmeterio, quod fuerat quondam fratrum, quos* Freres Pies *vetera appellabant.*

PIESMA, a word used by the ancients to express the remaining mass after the expression of any fluid substance from among its more solid parts. Thus the cake remaining in the bag after the expression of oils, is called by this name: but there are instances of authors calling the expressed juice, instead of the residuum, by this name. Thus Dioscorides calls the expressed juice of the bay-berries, the *piesma laurinum*; and others, the expressed juice of roses, *piesma rosarum*, paying no regard to the rose-cake left behind.

PIESTER, the name used by the ancients for the press which they employed in preparing the several juices of plants, &c. hence the word *piesma*, which see.

PIESTRON, a word used by Hippocrates to express a sort of forceps, which he recommends to be used in difficult labours, to break the bones of the cranium of the fœtus, when its head is too large to suffer it to pass whole. It was also called *embryulcus*.

PIETANIA, or PITTANCE, a portion of victuals distributed to the members of a college, or other community, upon some great festivals.

PIETANIARIUS. See PITANCIARIUS.

PIETERMAN, in *Ichthyology*, the name used by some for a fish of the cordus kind, approaching to the nature of the *draco marinus*, or weaver; and more usually called among authors by its Brasilian name RIQUI. See TAB. III. *of Fish*, N° 249.

PIETISTS, a religious sect that sprung up towards the close of the seventeenth century, among the Protestants of Germany; seeming to be a kind of mean between the Quakers of England, and the Quietists of the Romish church.

This sect originated in the zeal of certain persons, who, with the best intentions, endeavoured to stem the torrent of vice and corruption, and to reform the licentious manners both of the clergy and of the people. However, many, deluded by the suggestions of an irregular imagination, and an ill-informed understanding, or guided by principles and views of a more criminal nature, spread abroad new and singular opinions, false ethics, unintelligible maxims, austere precepts, and imprudent clamours against the discipline of the church; all which excited the most dreadful tumults, and kindled the flames of contention and discord.

The learned Spener was at the head of the first reformers, who, by the private societies he formed at Francfort, with a design to promote vital religion, roused the lukewarm from their indifference, and excited a spirit of vigour and resolution in those who had been satisfied to lament in silence the progress of impiety. With this view he published a book, intitled Pious Desires, in which he represented in an affecting manner the disorders of the church, and proposed the remedies that were proper to heal them. The religious meetings above mentioned, or colleges of piety, as they were called, however well designed in their original establishment, tended in many places to kindle in the breasts of the multitude the flames of a blind and intemperate zeal, whose effects were impetuous and violent: so that these institutions of *pietism* became objects of reproach and occasions of complaint.

The tumult thus produced was further promoted by the commotions that arose at Leipsic in the year 1689, when certain pious and learned professors of philosophy, undertook to explain the Scriptures in their colleges, with a view of forming candidates for the ministry into a more accurate acquaintance with these sources of religious knowledge. The novelty of this method of instruction excited attention, and the lectures that were delivered to this purpose were much frequented. Suspicions and rumours of an unfavourable kind were soon industriously propagated, and the professors were prohibited from pursuing the plan of religious instruction which they had undertaken. During these troubles and divisions, the invidious denomination of *Pietists* was first invented; or at least, before this period it was not commonly known. It was originally applied by some inconsiderate persons to those who frequented the biblical colleges, and lived in a manner suitable to the instructions and exhortations that were there addressed to them; and afterwards it was used to characterise all who were distinguished by the excessive austerity of their manners, or, who, regardless of truth and opinion, were only intent upon practice, and turned the whole vigour of their efforts towards the attainment of religious feelings and habits. At this time the denomination was also sometimes applied to persons whose motley characters exhibited an enormous mixture of extravagancy and enthusiasm, and who better deserved the title of delirious fanatics. The contest, thus begun, very soon spread through all the Lutheran churches in the different states and kingdoms of Europe. Many persons of various ranks and professions, of both sexes, learned and illiterate, pretended a divine impulse for pulling up iniquity by the root, and restoring to its primitive lustre the declining cause of piety and virtue, and for establishing a better discipline in the Christian church. Assemblies similar to those established by Spener were introduced for this purpose into Leipsic and other places: but they were not all conducted with prudence and order. Into these assemblies there were introduced several extravagant and bare-headed fanatics, who foretold the destruction of Babel, i. e. the Lutheran church; who terrified the populace with fictitious visions, assumed the authority of prophets honoured with a divine commission, revived doctrines that had long before been exploded and condemned, declared the approach of the millennium, and were guilty of many outrages against order and peace. The governors of the church and of the state were alarmed at the progress of the divisions which these enthusiasts produced, and many severe laws were enacted against the *Pietists*.

These restorers of piety were of two kinds: one sect, at the head of which was Spener, proposed to carry on their plan without introducing any change into the doctrine, discipline, or form of government in the Lutheran church: the other party were for introducing considerable alterations both in doctrine and ecclesiastical polity. Many mistakes have been occasioned by confounding these two parties: the former of which were zealously intent upon a very important object, the revival of piety, and with this view, the reformation of public seminaries, where ministers were educated, both as to the mode of instruction and the extent of discipline: but the latter were, for the most part, totally deficient of reason and judgment: their errors were the results of a disordered brain; and they were rather to be considered as lunatics than as heretics. Some among them were less extravagant, and tempered the singular notions they had derived from reading meditation, with a certain mixture of the important truths and doctrines of religion. They were mostly, however, of the mystic kind. For a more particular account we must refer to Mosheim's Eccl. Hist. vol. iv. p. 454, &c. Eng. edit. 8vo.

Many gross errors are charged on the *Pietists*, in a book intitled Manipulus Observationum Antipietisticarum; but they have too much the severity of polemical exaggeration: at least it is certainly so with regard to a great part of them.

In effect, there are *Pietists* of several kinds: some run into gross illusions, and carry their errors to the overturning a great part of the Christian doctrine; others are only visionaries; and others very honest and good people, who, disgusted with the coldness and formality of other churches, and charmed with the fervent piety of the *Pietists*, are attached to their party, without giving into the grossest of their errors.

PIETISTS, otherwise called the *brothers and sisters of the pious and christian schools*, a society formed in the year 1678, by Nicholas Barre, and obliged, by their engagements, to devote themselves to the education of poor children of both sexes.

PIETOSA, in the *Italian Music*, signifies to play or sing in a soft manner, fit to move pity or compassion.

PIETRA *embolsata*, in *Natural History*, a name given by the Italians to the Florentine marble, so remarkable for its delineations.

This marble is found in thin strata, and is full of cracks; in these cracks there is usually found a black mineral matter, which, getting into the substance of the stone a little way on each side of the crack, forms there various delineations, or the figures of pieces of moss, bushes, and the like: the paler pieces of the marble usually have these delineations; the darker coloured [illegible] the forms of trees and houses, or the ruins of [illegible]

PIETY, *manuals of*. See [illegible]

PIEXE-*pala*, in *Ichthyology*, a [illegible] genus of a fish caught about [illegible] much resembling our *acer* [illegible] known among authors [illegible] TUAIA.

PIEXE-*puros*, in *Ichthyology* [illegible] have called the *weever*; [illegible] name is Portuguese, and [illegible] ture having a mouth like a hog.

PIG, *Guinea*. See GUINEA.

PIG *of lead*, the eighth part of a [illegible] about 256 *lb.* weight.

PIGAYA, in *Natural History*. See [illegible]

PIGEON, *columba*, in the Linnæan system of [illegible]

is a distinct genus of birds of the order of the PASSERES; the characters of which are, that the tongue is whole and even; the beak straight, and scurfy at the base; the noſtrils long, and covered externally with a tumid membrane. Linnæus enumerates forty species.

The tame *pigeon*, and all its beautiful varieties derive their origin from one species, the stock-dove. Varro obſerves, that they derive their Latin name *columba* from their voice or cooing. They were and ſtill are in moſt parts of our iſland, in a ſtate of nature; they breed in holes of rocks and hollows of trees. They are gregarious in their nature, lay only two eggs, and breed many times in the year, ſo that it is ſaid, fourteen thouſand ſeven hundred and ſixty may be produced in four years from a ſingle pair; they bill in their courtſhip; the male and female ſit by turns, and feed their young; they caſt their proviſion out of their craw into the young ones mouths; they drink by continual draughts, like quadrupeds, and their nares are membraneous or pilatrive.

Many of them are obſerved to migrate into the ſouth of England, not appearing with us till November, and retiring in the ſpring. Their ſummer haunts are probably in Sweden. The varieties produced from the domeſtic pigeon are very numerous and extremely elegant; they are diſtinguiſhed by names expreſſive of their ſeveral properties, ſuch as TUMBLERS, CARRIERS, JACOBINES, CROPPERS, POUTERS, RUNTS, TURBITS, OWLS, NUNS, &c. Pennant.

PIGEON, *Barbary*. See BARB.

PIGEON, *helmet*. See HELMET.

PIGEON-*holes*, in *Brick-Making*. See BRICK.

PIGEON-*pea*, in *Botany*. See *Cytiſus* TREFOIL.

PIGEON, *laughing*. See LAUGHER.

PIGEON, *Alabama*. See MARIGNY.

PIGEON-*houſe*, a houſe erected full of holes within, for the keeping, building, &c. of pigeons otherwiſe called a dove-cote. Any lord of a manor may build a *pigeon-houſe* on his land, but a tenant cannot do it without his lord's leave. When perſons ſhoot at or kill *pigeons* within a certain diſtance of the *pigeon-houſe*, they are liable to pay a forfeiture.

PIGER *Henricus*, ſloth'ful Harry, a fantaſtical name for a ſlow diſtilling chemical inſtrument; called alſo an ATHANOR.

PIGMENTS, *pigmenta*, preparations in a ſolid form, uſed by painters, dyers, &c. to impart colours to bodies, or to imitate particular colours.

Theſe require to be mixed with ſome fluid, as a vehicle, before they can be employed as paints, except in the caſe of crayons, where they are uſed dry.

When glaſs is ſtained, or coloured, as in painting on glaſs, or for counterfeiting gems, or precious ſtones; the *pigment* is always of a metalline, or a mineral nature.

In the gilding of wood, *pigments*, approaching as near as may be to the colour of gold itſelf, are both laid under the gold, and uſed alſo for the colouring of depreſſed parts, where gold leaf cannot be conveniently applied. The ſubſtance chiefly employed for this purpoſe is yellow ochre, the colour of which may be improved by a ſmall addition of vermilion or other red powders. See GILDING.

PIGMY, or PYGMY. See PYGMY.

PIGNE. See PINEA.

PIGNOLETTI, in *Ichthyography*, a name uſed by many for the ×PHUS *cabites*, a ſmall fiſh of the *gobius* or ſea-gudgeon kind, common in the Mediterranean, and brought to the markets of Rome and Venice.

PIG-*nut*, or RAGG-*nut*, *bunium*, in *Botany*, a genus of the *pentandria digynia* claſs. Its characters are theſe: the involucrum of the great umbel is compoſed of many ſhort narrow leaves; and the proper empalement of the flower is ſcarcely diſcernible; the *flowers* have five heart-ſhaped petals which are equal and turn inward; and they have five ſtamina; the oblong germen is ſituated below the receptacle, which afterwards becomes an oval fruit dividing into two parts, containing TWO oval ſeeds. Miller enumerates three ſpecies, which delight to grow among graſs, to cannot without difficulty be made to thrive long in a garden. Linnæus mentions only one ſpecies.

The root of this plant, which is the only part uſed, and either roaſted or raw, is of a pleaſant ſweetiſh taſte: it is accounted nouriſhing, and to be provocative of venery; it is commended againſt the ſtrangury, and bloody urine.

PIG-*nut*. See WALNUT-*tree*.

PIGUS, in *Ichthyology*, the name of a ſpecies of leather-mouthed fiſh, very much approaching to the nature of the carp.

It is of the ſame ſhape and ſize with the common carp, and has the eyes, fins, and fleſhy palate wholly the ſame; from the gills to the tail there runs a crooked dorſal line; the back and ſides are bluiſh, and its belly reddiſh; it is covered with large ſcales, from the middle of every one of which there riſes a fine, pellucid, and very ſharp prickle.

It is a finer fiſh than the carp for the table, and is in ſeaſon in the months of March and April. It is caught in lakes in ſome parts of Italy, and is mentioned by Pliny, though without a name.

It is a ſpecies of *cyprinus*, according to Artedi, and is diſtinguiſhed by that author under the name of the *cyprinus*, called *picta* and *pigus*. He adds, that the tail is forked, and the ſcales large; and that in ſpring and autumn there grow out of them white pyramidal prickles, which remain about five or ſix weeks, and then fall off; the back is of a blackiſh hue, and the belly white, with a faint caſt of red. It never grows to more than five or ſix pounds: the fleſh is well taſted. It is found in the lakes in the northern nations.

PIISSKER, in *Ichthyology*, the name of a fiſh of the *muſtela* kind, uſually called the *monſtrous foſſilis*, or *piſcis foſſilis*, the *foſſile fiſh*.

This fiſh is uſually found of a hand's breadth long, and as thick as one's finger; but they grow ſometimes to be much longer: the back is of a grey colour, ſpotted with a great number of ſpots and tranſverſe ſtreaks, partly black and partly blue; the belly is yellow, and is ſpotted with red and white and black: the white ones are the larger, the others look as if made with the point of a needle; and there is on each of the ſides a longitudinal black and white line. There are certain fleſhy excreſcences at the mouth, which, in ſwimming, they expoſed; and when out of the water, they contract them. They run into caverns in the earth, in the ſides of rivers, in marſhy places, and penetrate a great way, and are frequently dug up at conſiderable diſtances from waters; and often when the waters of brooks and rivers ſwell beyond their banks, and they are ſeen covered by them, they make their way out of the earth into the water; and when it deſerts them, they are left in vaſt numbers upon the ground, when they are eaten by the ſwine.

This ſeems very much of the kind of the *foſſilis* fiſh, and poſſibly is no other than the ſame ſpecies; and poſſibly alſo the *perilla* of Schoneveldt is the ſame.

PIKE, an offenſive weapon, conſiſting of a ſhaft of wood, twelve or fourteen feet long; headed with a flat-pointed ſteel, called the *ſpear*.

The name *pike* is ſaid to be derived from a bird, called by the French *pic*, by us wood-pecker; whoſe bill is ſaid to be ſo ſharp as to pierce wood like an augre. Du Cange derives it from the baſe Latin *picus*, or *picea*; which Turnebus ſuppoſes to have been ſo called, *quaſi ſpicea*, becauſe reſembling an ear of corn: Octavio Ferrario derives it *a ſpicula*. M. Fauchet ſays, it was the *pike* that gave name to the Picards, and to Picardy, which he will have to be modern, and to have been framed on occaſion of that people's renewing the uſe of the *pike*; the etymology whereof he fetches from the French *piquer*, to *pick*. But others will have the name *Picard* to have been given that people by reaſon of their readineſs to pick quarrels; called in French *picqueurs*.

The *pike* was a long time in uſe in the infantry, to enable them to ſuſtain the attack of the cavalry; but it is now taken from them, and the bayonet, which is fixed to the muzzle of the firelock, is ſubſtituted in its place.

It is ſtill uſed by ſome officers of infantry under the name of ſpontoon.

Pliny ſays, the Lacedæmonians were the inventors of the *pike*. The Macedonian phalanx was evidently a battalion of *pikemen*.

PIKE, *in Ichthyology*, a name given by us to the fiſh called by authors the *ſuculus* and *eſox*, and by the old Greek writers *belone*.

This is the *ſuculus* ROSTRO of Linnæus: its characters are, that the head is very flat; the upper jaw broad, and ſhorter than the lower, which turns up a little at the end; the body is long, ſlender, and compreſſed ſideways; the teeth are very ſharp, diſpoſed only in the front of the upper jaw, but in both ſides of the lower, in the roof of the mouth, and often the tongue; the fin of the mouth is very wide, and the eyes ſmall; the dorſal fin is placed very low on the back, and conſiſts of twenty-one rays; the pectoral of fifteen; the ventral of eleven; and the anal of eighteen; the tail is bifurcated. The *pike* is common in moſt of the lakes of Europe, but the largeſt are thoſe of Lapland, which are ſometimes eight feet long: they are there dried and exported for ſale. It is ſaid, that the *pike* was introduced into England in the reign of Henry VIII. in 1537, when a *pike* was ſold for double the price of a horſe-lamb in February. Beſides fiſh and frogs, which are its uſual food, it will devour the water rat and young ducks. It is very fierce and voracious. This fiſh is very remarkable for its longevity: we read of one that was ninety years old, and of another, that was not leſs than two hundred and ſixty-ſeven years old.

Pennant.

Pennant. See *Fading of* FISH, *Pike-*FISHING, and HAXING.

PIKE, *land.* See LUCIUS *terrestris.*

PIKE-*perch.* See LUCIO-*perca.*

PIKE, *sea.* See MERLUCIUS and SCUDI.

PIKE, in *Commerce.* To treat at the *pike*, or *pike's end, à la pique*, denotes a kind of commerce, which the Europeans hold with savage nations, wherein they are to keep on their guard, and, as it were, sword in hand.

To count at the pike also denotes a kind of prohibited traffick which the English, French, and Dutch, maintain in several parts of the Spanish West Indies, near the colonies which those nations have in the Caribbee islands.

Perhaps it should rather be called *treating at pike*, i. e. with the vessel at anchor; in regard this commerce, which is prohibited on pain of death, is only practised in roads where vessels lie at anchor, waiting for the Spanish merchants, who sometimes by stealth, though more frequently with the connivance of the governors, &c. come to exchange their gold, pieces of eight, cochineal, &c. for the European merchandizes.

Others will have it treating at the *pike*, i. e. at a *pile's length*, or *distance*; by reason of the distance strangers are obliged to keep at.

PIKE, is also the name of an Egyptian measure, of which there are two kinds, the large and the small.

The larger *pike*, called also the *pike* of Constantinople, is 27.$\frac{1}{2}$ English inches. They measure all foreign goods with this, except only such as are made of flax and cotton: for these they use the small *pike*, called *pike bellicle*, or the *pike* of the country; because they measure with it all the manufactures of the country. This *pike* consists of about 25.$\frac{1}{2}$ English inches.

PIKE, *half*, in the *Military Art*, is the weapon carried by an officer of foot. It differs from a *pike*; because it is but eight or nine feet long, and the spear is smaller and narrower. See SPONTOON.

PILA. See PILE.

PILA, PILE, in *Building*, a mass of masons work, in manner of a pillar; used hexagonal. See PIER.

The word comes from the Latin *pila*, used in the same sense by Vitruvius; and this probably from πιλος, *coges vortico.*

Evelyn observes, that *piles*, and their quoins, as we see them in ancient altars and monuments, were used for insculptions; but the shorter and more massy served for arches and buttresses to solid work. They are sometimes made semicircular; but the ancients preferred those pointed at right angles; as best able to resist the current.

PILA *marina*, the *sea-ball*, in *Natural History*, the name of a substance very common on the shores of the Mediterranean, and in some other places. It is usually found in form of a ball, about the size of the balls of horse-dung, and composed of a multitude of fibrillæ, irregularly complicated.

Its origin has been very variously guessed at by different authors. John Bauhine says, that it consists of small hairy fibres, and straws, such as are found about the fea-plant called *alga cornifera*; but he does not pretend to ascertain what plant it owes its origin to. Imperatus judged it to consist of the ravelly both of vegetable and animal bodies. Mercatus doubts whether it be a congeries of the fibrillæ of plants, wound up into a ball by the motion of the sea-water; or whether it be not the workmanship of some sort of beetle living about the sea-shore, and analogous to our common dung beetles ball, which it elaborates from dung for the reception of its progeny. Schwenkius will have it composed of the filaments of some plant of the red kinds: and Welchius supposes it to consist of the pappose part of the flowers of the reed. Maurice Hoffman thinks it the excrement of the hippopotamus: and others think it that of the phoca, or sea calf.

But Klein, who had thoroughly examined as well the balls themselves, as what authors had conjectured concerning them, is of opinion, that they are wholly owing to, and entirely composed of, the capillaments which the leaves growing to the woody stalk of the *alga cornifera* have, when they wither and decay. These leaves, in their natural state, are about the thickness of a wheat straw, and they are placed so thick about the tops and extremities of the stalks, that they enfold, embrace, and lie over one another; and from the middle of their clusters of leaves, and, indeed, from the woody substance of the plant itself, there arise several other very long, flat, smooth, and brittle leaves: these are usually four from each tuft of the other leaves, and they have ever a common vagina, which is membranaceous and very thin. This is the style of the plant, and the *pila marina* seems a collect of the fibres of the leaves of this plant, which cover the whole stalk, divided into their constituent threads, and by the motion of the waves, first broken and worn into short shreds, and afterwards wound up together into a roundish or longish ball. Klein, de Tubul. Marin. p. 22.

PILARIS, or PILARIS *turdus*, in *Ornithology*, the name by which authors in general call the VISCI-*vorus.*

PILASTER, in *Architecture*, a square column, sometimes insulated, but more frequently set within a wall, and only projecting with a fourth or fifth part of its thickness. See *Tab. Architect. fig.* 20. (*k*)

The *pilaster* is different in different orders; it borrows the name of each order, and has the same proportions, and the same capitals, members, and ornaments, with the columns themselves.

Pilasters in the Attic order are represented at Y *fig.* 40. They are sometimes at equal distances, and sometimes coupled; but this depends on the intercolumniation of the order below. If the Attic order be straight, and immediately over it, it must partake of the same distances and stand over the columns in the lower order.

Pilasters are made usually without either swelling or diminution, as broad at top as at the bottom; though some of the modern architects, as M. Mansard, &c. diminish them at top, and even make them swell in the middle, like columns; particularly when placed behind columns.

Pilasters, M. Perrault observes, like columns, become of different kinds, according to the different manner wherein they are applied to the wall. Some are wholly detached, called by Vitruvius *parastatæ*; others have three faces clear out of the wall; and others two; and others only one: these are all called by Vitruvius *antæ.*

Insulate *pilasters* are but rarely found in the antique. The chief use they make of *pilasters* was at the extremities of porticoes, to give the greater strength to the corners.

There are four principal things to be regarded in *pilasters*; viz. their projecture out of the wall, the diminution, the disposition of the entablature when it happens to be common to them, and to a column, and their flutings and capitals.

1. The projecture of *pilasters* which have only one face out of the wall, is to be one eighth of their breadth; at most, not above one-fifth. When they receive imposts against their sides, their projecture may be a quarter of their diameter.

They are made to project in different proportions to their diameters, as one-eighth, one-fourth, one-half, and three-fourths; but are never used gracefully quite a square, except at angles; and then only in massive buildings, as the portions of St. Paul's, Covent-garden.

2. *Pilasters* are but seldom diminished, when they have only one face out of the wall. Indeed where they stand in the same line with columns, and the entablature is continued over both, without any break, the *pilasters* are to have the same diminution with the columns, that is to say, on the face respecting the column; the other being left without any diminution.

When they are diminished they have an ill effect where it becomes necessary to make them correspond with the lines of the columns at top, as is sometimes the case in porticos and returns, then it is better for the architect to make them entirely of the smallest diameter of the column to which they are opposed.

3. *Pilasters* are sometimes fluted, though the columns they accompany be not so; and, on the other hand, the columns are sometimes fluted, when the *pilasters* that accompany them are not.

The flutings of *pilasters* are always odd in number, except in half *pilasters*, meeting at inward angles; where four flutings are made for three, &c.

4. The proportions of the capitals of *pilasters* are the same as to height with those of columns, but they differ in width, the leaves of the former being much wider, because *pilasters*, though of equal extent, have only the same number of leaves for their girt, viz. eight. Their usual disposition is to have two in each face in the lower row, and in the upper row one in the middle, and two halves in the angles, in the turns where they meet. Add to this that the rim of the vase, [illegible] it not straight, as the lower part is, but a little [illegible] prominent in the middle.

In *pilasters* that support ARCHI[illegible] the flowers, must be regulated [illegible] and at angles by the [illegible] which reason, keys in Rustic [illegible] best becomes them.

PILASTER, *demi*, called also [illegible] on an arch: it generally [illegible]

PILATIO, a word used by [illegible] fissure in the cranium, [illegible] of the head.

PILATRO, or PILATRO, *de* [illegible] girls made in some parishes [illegible]

from the froth of the sea, coagulated by heat in the hot countries.

PILCHARD, in *Ichthyology*, a fish much approaching to the nature of the common herring, but smaller and differing in several other particulars.

The distinguishing characters of it are these: the body of the *pilchard* is less compressed than that of the herring, being thicker and rounder; the nose is shorter in proportion, and turns up; the under jaw is shorter; the back is more elevated; the belly less sharp; the dorsal fin of the *pilchard* is placed exactly in the centre of gravity, so that when taken up by it, the body preserves an equilibrium, whereas that of the herring dips at the head; the scales of the *pilchard* adhere very closely, whereas those of the herring very easily drop off. Pennant.

It is generally found swimming in vast shoals, and is caught on many parts of the English coasts. Its flesh is better tasted than that of the herring. See *Pilchard* FISHERY.

PILE, in *Antiquity*, a pyramid built of wood, wherein were laid the bodies of the deceased, to be burnt.

PILE is also used in building, for a great stake rammed into the earth, for a FOUNDATION to build upon in marshy ground.

Amsterdam, and some other cities, are wholly built upon *piles*. The stoppage of Dagenham-breach is effected by dove-tail *piles* that is by *piles* mortised into one another, by a dove-tail-joint.

To estimate the force of the rammer made use of to drive *piles*, its weight ought to be multiplied into the velocity it acquires in falling. Thus, if a rammer which weighs 500lb. be let fall from four feet, it will fall that height in half a second, and have at the time of percussion a velocity capable to carry it uniformly eight feet in half a second, without any further help from gravity; so that we must multiply 500 by 8, or its weight by the number of feet it would fall in a second, and the product 8000 gives the momentum of the stroke. If a capstan, pullies, or windlass be made to raise the rammer to a considerable height, and then by an easy contrivance loosen it at once from its hook, the momentum of the stroke will always be as the square root of the height from which the rammer fell.

But it is to be observed, that the effect of the blow of the rammer will be as the square of its velocity; that is, as the height from whence it falls, and not as the square root of that height. Thus if the blow of the rammer drive the *pile* six feet deep, a blow given with twice the velocity, will, *ceteris paribus*, drive it twenty-four feet deep. This follows from the nature of the force of bodies in motion. See FORCE, Dcfag. Exp. Phil. vol. I. p. 330, &c.

We have the figure and description of a new machine for driving *piles*, invented by Mr. Valour, in Desaguliers Experim. Philosoph. vol. II. p. 417, 3d. and in Ferguson's Lectures, p. 61, quarto.

As this is the most complete engine of this kind that has yet been constructed, though others have been described by Leopold, Desaguliers, and Belidor, the following account, illustrated by a figure, may be agreeable: A (*Plate VI. Mechanics, fig. 9.*) is the great upright shaft or axle, on which are the great wheel B and drum C, turned by horses joined to the bars S, S. The wheel B turns the trundle X, on the top of whose axis is the fly O, which serves to regulate the motion, and to act against the horses, and keep them from falling when the heavy ram Q is discharged to drive the *pile* P down into the mud in the bottom of the river. The drum C is loose upon the shaft A, but is locked to the wheel B by the bolt Y. On this drum the great *rope* HH is wound; one end of the rope being fixed to the drum, and the other to the follower G, to which it is conveyed over the pulleys I and K. In the follower G is contained the tongs F that take hold of the ram Q, by the staple R for drawing it up. D is a spiral or lance fixed to the drum, on which is wound the small rope T that goes over the pulley U, under the pulley V, and is fastened to the top of the frame W. To the pulley-block V is hung the counterpoise W, which hinders the follower from accelerating as it goes down to take hold of the ram: for, as the follower tends to acquire velocity in its descent, the line T winds downwards upon the spiral, on a larger and larger radius, by which means the counterpoise W acts stronger and stronger against it, and so allows it to come down with only a moderate and uniform velocity. The bolt Y locks the drum to the great wheel, being pulled upward by the lever Z, which goes through a mortise in the shaft A, as at *a*, and is fixed in the bar 3 fixed into the great wheel B, and has a weight 4, which always tends to push up the bolt Y through the wheel into the drum. L is the great lever turning on the axis *m*, and resting upon the forcing bar 5, 5, which goes down through a hollow in the shaft and bears upon the little lever 2.

By the horses going round, the great rope H is wound about the drum C, and the ram Q is drawn up by the tongs F in the follower G, until the tongs come between the inclined planes E, which, by shutting the tongs at the top, open it at the foot, and disengage the ram, which falls down between the guides 6, 6 upon the *pile* P, and drives it by a few strokes as far into the mud as it can go; after which the top part is sawed off close to the mud, by an engine for that purpose. Immediately after the ram is discharged, the piece *o* upon the follower G takes hold of the ropes *n*, *n*, which raise the end of the lever L, and cause its end N to descend and push down the forcing bar 5 upon the little lever 2, which, by pulling down the bolt Y, unlocks the drum C from the great wheel B; and then the follower, being at liberty, comes down by its own weight to the ram; and the lower ends of the tongs flip over the staple R, and the weight of their heads causes them to fall outward, and then upon it. Then the weight 4 pushes up the bolt Y into the drum, which locks it to the great wheel, and so the ram is drawn up as before.

As the follower comes down, it causes the drum to turn backward, and unwinds the rope from it, whilst the horses, great wheel, trundle, and fly, go on with an uninterrupted motion: and as the drum is turning backward, the counterpoise W is drawn up, and its rope T wound upon the spiral furse D.

There are several holes in the under side of the drum, and the bolt Y always takes the first one that it finds when the drum stops by the falling of the follower upon the ram; until which stoppage, the bolt has not time to slip into any of the holes.

The peculiar advantages of this engine are, that the weight, called the ram, may be raised with the least force; that, when it is raised to a proper height, it readily disengages itself and falls with the utmost freedom; that the forceps or tongs are lowered down speedily, and instantly, of themselves, again lay hold of the ram, and lift it up; on which account this machine will drive the greatest number of *piles*, in the least time, and with the fewest labourers.

The theory of this engine depends on the following principles: viz. 1. If the resistance of the ground, and the masses of the *piles* be equal, the depths to which they will be driven with a single blow will be as the product of the weight of the ram into the height through which it falls.

2. If the masses of the ram, and heights through which it falls are both equal, the depths to which the *piles* will be driven, will be in the inverse ratios of the masses of the *piles* into the superficies of that part of them which is already immersed in the earth.

3. If all these things be unequal, the depths will be in a ratio compounded of the direct ratio of the heights through which the ram falls into its mass, and the inverse ratio of the mass of the *pile* into its immersed superficies.

4. If the weights of the ram be equal, and also the weights of the *piles*, the depths to which they will be driven will be as the heights through which the ram falls directly, and the immersed superficies of the *piles*. Or, because the immersed superficies of the *piles* are as the depths through which they are already driven into the earth, these depths are simply as the square roots of the heights through which the ram falls.

These principles are founded on the general supposition that the space through which the weight falls is eliminated by the product of its mass into the square of its velocity, or into the height through which it falls.

Hence it is inferred, that the distance through which a *pile* will be driven by each succeeding blow will be less and less, as the superficies of that part of the *pile* which is immersed in the ground increases; and, consequently that there is a certain depth, beyond which a *pile* of a given mass and figure cannot be driven; the mass of the ram and the height through which it falls at first being assigned. It appears also, that the loading the *pile* with weights, and thereby increasing its mass, will be so far from accelerating its descent, that it will absolutely retard it. See some curious observations on the structure and operation of this engine by Mr. Bugge, professor of astronomy and mathematics in the academy of Copenhagen, &c. in the Phil. Trans. for 1758, vol. lvii. part i. art. 12.

PILE is also used, among *Architects*, for a massive body of building.

PILE, in *Artillery*, denotes a collection or heap of shot or shells which are usually piled up by horizontal courses into a pyramidal form, the base being either an equilateral triangle, a square, or a rectangle. In the triangle and square, the *pile* terminates in a single ball; but in a rectangle, in a single row of balls. In the triangle and square *piles*, the number of horizontal rows, or the number counted on one of the angles from the bottom to the top, is always equal to the number counted on one side, in the bottom

bottom row. In triangular *piles*, each horizontal course is a triangular number, produced by taking the successive sums of the numbers 1 and 2; 1, 2, and 3; 1, 2, 3, and 4; *&c.* And the number of shot in a triangular *pile* is the sum of all the triangular numbers taken as far, or to as many terms, as the number in one side of the bottom course. In order to obtain the number in a triangular *pile*, count the number in the bottom row, and multiply that number more two by that number more one; and the product multiplied by one-fifth of the said number will be the whole sum required.

In square *piles*, each horizontal course is a square number, produced by taking the square of the number in its side: and the number of shot in a square *pile* is the sum of all the squares, taken from one as far as the number in the sides of the bottom course. To find the number, count the number in one side of the bottom course; to that number add one, and to its double add one; multiply the two sums together, then their product being multiplied by one-fifth of the said number will give the required number of shot in the *pile*.

From the examplification of these rules, it would appear, that when room is wanted, it is most convenient to stow the shot in triangular *piles*; for on the equilateral triangle, which is less than half the area of a square of one of its sides, there can be piled a greater number than half of those that can be raised on the square: and the height of a square *pile* is somewhat less than that of a triangular one; because a shot will sink lower in the space between four others, than between three others, when they are of equal diameter.

In rectangular *piles*, each horizontal course is a rectangle, the upper one being one row of balls: and every such oblong *pile* may be considered as consisting of two parts, one a square pyramid, and the other a triangular prism. To find the number of shot in a rectangular *pile*, take the difference between the number in length and breadth, in the bottom course; multiply the number in breadth, more one, by half the breadth; the product multiplied by the said difference will give the number in the prismatic *pile*: upon the square of the breadth, find the number in a pyramidal *pile*; and the sum of these two *piles* will give the number required. See CALIBER, and *Tab. Gunnery, fig.* 8.

PILE, PILL, in *Coinage*, denotes a kind of puncheon, which, in the old way of coining, with the hammer, contained the arms, cross, or other figure and inscription, to be struck for the reverse of the species.

Accordingly, we still call the arms-side of a piece of money the *pile*, and the head the *cross*; because, in the ancient money, a cross usually took the place of the head in our's.

Hence also the game of *cross* and *pile*.

Some will have it called *pile*, *pila*, because on this side, in our ancient coins, there was an impression of a church built on *piles*. Scaliger, with more probability, derives it from the old French word *pile*, a *ship*. Vide prima Scaligerana, in voc. Nummus Flaticus, p. 115.

In some ancient writings *pile* is used to signify the particular figure, or impression of money. Thus Fleta: he who brings an appeal of robbery, or theft, against another, shall throw the certain quantity, quality, price, weight, number, measures, value, and *pile*.

PILE, in *Heraldry*, is an ordinary, in form of a point inverted, or a flake sharpened; contracting from the chief, and terminating in a point towards the bottom of the shield; somewhat in manner of a wedge. See *Tab.* II. *Herald. fig.* 80.

It is formed, probably, in imitation of the Roman pilum, which was a tapering dart, about five feet long, and sharpened at the point with steel.

The *pile* is borne inverted, engrailed, *&c.* like other ordinaries; and thus indifferently from any point of the verge of the escutcheon. He beareth a *pile gules*, by the name of Chandos.

PILES, in *Medicine*, a disease by physicians called HEMORRHOIDS.

PILES, *Instrument for the*. See LENTIGENT.

PILE-*worms*, are a kind of *worms* found in the *piles* of the sea-banks in Holland. These worms are of various sizes; some of the young ones are not above an inch or two in length; but others have been found thirteen or fourteen inches long.

The heads of these creatures were covered with two hard shells or *hemicranias*, which together form a figure resembling an augre; and with which they bore the wood. The best remedy against them is, to perforate the *pile* with many small holes, about an inch asunder; then it must be done over with a varnish in the hottest sun; and while the varnish is hot, brickdust must be strewed over it; and this being several times repeated, the *pile* will be covered with a strong crust, impenetrable to all insects.

See a further account of these creatures in Phil. Trans. N° 455. sect. 5.

PILE-*wort*, in *Botany*. See RANUNCULUS.

PILEÆ, a name given by some authors to a genus of *mushrooms*. See CONCHA.

PILENTUM, among the Romans, an easy kind of chariot, used by the Roman ladies at games and religious processions.

PILETUS, in our *Ancient Forest Laws*, an arrow which had a round knob a little above the head, to hinder it from going far into the mark.

From the Latin *pila*, which signifies any round thing like a ball. *Et quod foresters sic sua non perimbant sagittas barbatas, sed* piletas. Charta Rogeri de Quincy.

PILEUS, in *Roman Antiquity*, was the ordinary cap or hat worn at public shews and sacrifices, and by the freed-men. It was one of the common rewards assigned to such gladiators as were slaves, in token of their obtaining their freedom. See RUDIS.

PILEUS *prefixtel*, in *Botany*, a name given by some writers to the *euonymus* or *fusanus*, a shrub which grows in our hedges, and bears a square fruit somewhat resembling the cap worn by some orders of priests.

PILGRIM, one who travels through foreign countries to visit holy places, and to pay his devotion to the relicks of dead saints.

The word is formed from the Flemish *pelgrim*, or Italian *pelegrino*, which signifies the same; and these originally from the Latin *peregrinus*, *a stranger*, or *traveller*.

The humour of going on pilgrimage anciently prevailed exceedingly; particularly about the time of the croisades. *Pilgrimages* were most in vogue after the end of the eleventh century, when every one was for visiting places of devotion, not excepting kings and princes themselves; and even bishops made no difficulty of being absent from their churches on the same account. The places most visited were Jerusalem, Rome, Compostella, and Tours; but the greatest numbers now resort to Loretto, in order to visit the chamber of the blessed Virgin, in which she was born, and brought up her son Jesus, till he was twelve years of age.

This chamber, it is pretended, was carried by angels into Dalmatia, about the year 1291, and afterwards in the same manner transported to Loretto, where a magnificent cathedral is built over it. In this chamber is the image of the blessed Virgin, almost covered with pearls and diamonds, and round the statue there is a kind of rainbow, formed of precious stones of various colours. Five hundred thousand *pilgrims* have sometimes resorted to this house in one year, in order to pay their devotions before this glorious image.

Several of the principal orders of knighthood were established in favour of *pilgrims* going to the Holy Land, to secure them from the violences and insults of the Saracens and Arabs, *&c.*

Such were the orders of the knights Templars, the knights Hospitalers, knights of Malta, *&c.*

The MAHOMETANS are commanded in the Koran to perform a *pilgrimage* to Mecca; this is one of the capital points of their religion, and therefore a prodigious cavalcade of *pilgrims* annually go thither, in the company of those who are sent with the grand seignor's presents to the tomb of Mahomet.

PILIANNAW, a name given by the Indians to a bird found in the forests on the back of some of our American plantations.

It is a bird of prey, very large and bold; it is described by Josselin as four times as big as our goshawk, and having a remarkable large head. All the birds are terrified at its approach; but it principally feeds on quadrupeds, as young fawns, and the like.

PILIMICHIO, a word used by several authors to express a discharge of small and long filaments, which resemble hairs among the urine.

PILING. See PALLIFICATION.

PILL, *pilula*, in *Pharmacy*, a form of medicine, taken dry, resembling a little ball; invented in favour of [illegible] as cannot well take ill-tasted medicines [illegible] to keep in readiness for [illegible]. No medicine, that is intended [illegible] to be made into *pills*, as the [illegible] time in the Stomach before [illegible] produce any effect.

Pills are of various kinds, [illegible] carminative, purgative, hysteric, antiscorbutic, [illegible] but they principally cathartic.

The bases of cathartic *pills* [illegible] are mixed again, turbith, [illegible] hiera, [illegible] hiera picra, [illegible] turbith, [illegible] colocynth. See EXTRACT, [illegible]

Pills are usually wrapped up [illegible] powder, [illegible] the like, to prevent their ill taste [illegible]

PILLS, *antiseptic*, are directed by [illegible] Edinburgh

to be made of three parts of quicksilver, two parts of golden sulphur of antimony, and two of resin of guaiacum, with the addition of two of white soap to promote their dissolution in the stomach, and as much common syrup as will reduce them into a mass of due consistence. If a dram of this mass is made into twenty *pills*, the dose may be increased from one to six or more, according to the operation.

PILLS, *aromatic*, *pilulæ aromaticæ*, a form of medicine in the New London Dispensatory, intended to stand in the place of the *pilulæ diambræ* of the former, and the *pilulæ alephangiuæ*, or *alephangiuæ*, of that, and some other dispensatories.

The composition is this: take Socotrine aloes, an ounce and half; gum guaiacum, an ounce; the aromatic species and balsam of Peru, of each half an ounce; let the aloes and gum guaiacum be powdered separately, and afterwards mixed with the resin, and formed into a mass with syrup of orange-peel.

PILLS, *asses*, a sort of *pills* good against coughs, so called from the Greek, ἄσσα, *cough*. They are also called *hypoglottides*, because left like lozenges to dissolve under the tongue.

PILLS *of colocynth with aloes*, *pilulæ e colocynthide cum aloe*, a name given in the New London Pharmacopœia, to the purging-*pill*, commonly known by the name of *pilulæ cochiæ minores*.

As this is originally a prescription of Galen, and the manner of proportioning the ingredients has been altered for the worse, since his time, by enlarging the quantity of that nauseous ingredient the *colocynth*; the college have reduced it to its former proportions, and ordered it to be made in this manner: take Socotrine aloes and scammony, of each two ounces; pith of coloquintida, one ounce; oil of cloves, two drams; let the dry species be reduced to powder separately, the oil mixed among them, and the whole formed into a mass, with syrup of buckthorn.

PILULÆ *e colocynthide simplicieres*, a name given in the late London Pharmacopœia, to the purging-*pill* commonly known by the name of *pil. in duobus*. It is made of equal parts of colocynth and scammony, with a considerable proportion of oil of cloves; and is beat up to a consistence with syrup of buckthorn.

PILLS, *cumphine*, are made by beating together ten grains of purified OPIUM and half a dram of Castile soap: the whole may be formed into twenty *pills*; and one, two, or three, may be taken, as occasion requires, when a quieting draught will not sit upon the stomach.

PILLS, *fœtid*, are prepared by mixing half an ounce of ASSA FOETIDA with any simple syrup. In hysteric complaints, four or five *pills* of an ordinary size may be taken twice or thrice a day. They will also be of service to persons afflicted with the asthma; and they may be made opening, if necessary, by adding a proper quantity of rhubarb, aloes, or jalap, to the above mass.

PILLS *of gamboge*. See GAMBOGE.

PILLS, *hemlock*, are made by taking any quantity of the extract of HEMLOCK, and adding to it about a fifth part its weight of the powder of the dried leaves, and forming it into *pills*.

PILLS *for the jaundice* are prepared by taking of Castile soap, Socotrine aloes, and rhubarb, of each one dram, and making them into *pills*, with a sufficient quantity of syrup or mucilage. See JAUNDICE.

PILLS, *mercurial*, *pilulæ mercuriales*, a form of medicine prescribed in the late London Pharmacopœia, and containing crude mercury mixed for internal use.

The composition is to be made as follows: take of pure quicksilver, two drams; of Strasburg turpentine, two drams; of the cathartic extract, four scruples; rhubarb in powder, one dram; grind the quicksilver with the turpentine till it makes one uniform mass, and then add the other ingredients, and beat up the whole into *pills*. If the turpentine be too hard, it must be softened with a little oil of olives.

The mercurial *pills* may also be prepared by grinding half a dram of quicksilver, with equal its weight of resin of guaiacum, the same quantity of white soap, and a little common syrup or mucilage of gum arabic, which is to be added after the quicksilver is united with the others. In order to render the mercurial *pills* purgative, let the same quantity of mercury be first ground with half its weight of resin of guaiacum, and then with the same quantity of rhubarb and extract of black hellebore.

Mercurial *pills* may likewise be made, by rubbing together [illegible] purified mercury and honey, of each half an ounce, in a mortar, till the globules of mercury are perfectly extinguished; and adding two drams of Castile soap, and a sufficient quantity of powdered liquorice or crumbs of bread to give the mass a proper consistence. Equal parts of this mass, and powdered rhubarb formed into a mass with syrup, will make mercurial purging *pills*.

Mercurial sublimate pills are made by dissolving fifteen grains of the corrosive sublimate of mercury in two drams of the saturated solution of crude sal ammoniac, and making this into a paste, in a glass mortar, with crumb of bread. This mass must be formed into one hundred and twenty *pills*. These *pills* have been found effectual, not only in curing the venereal disease, but also in killing and expelling worms, after other powerful medicines had failed. For the venereal disease, four of these pills may be taken twice a day, as an alterant three, and for worms two.

PILLS, *Misaubin's*. See *Calomel* MERCURY.

PILLS, *perpetual*, *pilulæ perpetuæ*, are regulas of antimony made up in *pills*; thus called, because being swallowed and voided fifty times, they will purge every time with undiminished force.

PILLS, *Plummer's*. See PLUMMER'S *Pills*.

PILLS, *purging*. See PILLS *of Colocynth*, &c. *supra*.

Purging *pills* may be made of Socotrine aloes and Castile soap, of each two drams, and a sufficient quantity of simple syrup. Four or five of these will generally prove a sufficient purge. For keeping the body open, one may be taken night and morning. They are reckoned both deobstruent and stomachic, and will be found to answer all the purposes of Dr. Anderton's *pills*, the principal ingredient of which is aloes. When aloetic purges are improper, let *pills* be formed of extract of jalap, and vitriolated tartar, of each two drams, and a sufficient quantity of syrup of ginger; which may be taken as the above.

PILL, *Radius's*. See EXTRACTUM *Catharticum*.

PILLS, *soap*, *pilulæ saponatæ*, a form of medicine prescribed in the late London Dispensatory, and ordered to be made in the following manner: take almond *soap*, four ounces; strained opium, half an ounce; essence of lemons, a dram; soften the opium a little with wine, and beat that and the *soap* with the essence, till it be reduced to the form of a *pill*. See OPIUM.

This is intended to supply the place of the *pill*, commonly called *Matthew's pill*, and is very happily corrected in regard to the taste of the *soap*, by the addition of the essence of lemons.

PILLS, *squill*, are formed of a dram and a half of powder of dried squills; gum ammoniac, and cardamom seeds in powder, of each three drams, and simple syrup. In dropsical and asthmatic complaints, two or three of these *pills* may be taken twice a day.

PILLS, *stomachic*, are made of extract of gentian, two drams; powdered rhubarb and vitriolated tartar, of each one dram; oil of mint, thirty drops; and a sufficient quantity of simple syrup. Three or four of these may be taken twice a day, for invigorating the stomach, and keeping the body gently open.

PILLS *of storax*, are formed of fifteen parts of styraxed storax, eight of saffron, and two of strained opium.

PILLS, *strengthening*, are made of soft extract of the bark and salt of steel, of each half an ounce. In disorders arising from excessive debility or relaxation of the solids, as the *chlorosis* or green sickness, two of these *pills* may be taken three times a day.

PILL, *Ward's*. See WARD's *pills*.

PILLAGE, among *Builders*, is sometimes used for a square pillar, standing behind a column to bear up the arches; having a round base and capital, as a pillar has.

PILLAR, in *Architecture*, a kind of irregular column, round and insulate; but deviating from the proportions of a just column.

Pillars are always either too massive, or too slender, for a regular architecture. In effect, *pillars* are not restrained to any rules: their parts and proportions are arbitrary.

Such, e. gr. are the *pillars* which support Saracenic vaults, and other buildings, &c.

A square *pillar* is a massive work, called also PIER, or *pilaster*; serving to support arches. See *Butting-pillar* is a buttment, or body of masonry, raised to prop, or sustain, the thrust of a vault, arch, or other work. See BUTTRESS.

It seems not impossible for stone to be cast into the shape of *pillars*. We find mention made in the Philosophical Transactions, of two *pillars* of stone, at Fontesraud, in France, each about sixty feet high, all of one solid piece, which are said to have been run. N° 481, p. 328, in Not. *Pillars* of stone were anciently erected as sepulchral monuments, near the highways; and also in memory of some victory. We find traces of this custom in Cornwall and Wales, where these *pillars* are often found, and called *meinegwair*, a stone for play, perhaps in memory of funeral games; and sometimes *lech*, that is *tabula lusoria*. Phil. Trans. N° 450. p. 471.

Pompey's pillar is a famous monument of antiquity, constructed of red granite, and situated on a rock, about a mile without the walls of Alexandria, in Egypt. By the measuration of Edward Wortley Montagu, esq. the capital of the *pillar* is nine feet seven inches, the shaft five feet 11 inch, the base five feet nine 1 inches, the pedestal ten feet five 1 inches, the height from the ground ninety-two feet, though Dr. Pococke, by the shadow, determined the whole height to be one hundred and fourteen feet; and its diameter nine feet and an inch. This prodigious mass stands, as on a pivot, on a receptacle of rubble; and was erected, as many have supposed, either by Pompey, or to his honour. But as no mention is made of it by Strabo, or any other ancient writers, Mr. Montagu concludes that it was not known before the time of Vespasian; and that it was erected to his honour. In proof of this opinion, he found within the circumference of the *pillar* a medal of Vespasian in fine order. See Pococke's Descr. of the East, vol. i. p. 8. and Philos. Trans. vol. lvii. art. 42.

PILLAR, in the *Manage*, signifies the centre of the volta, ring, or manege-ground, round which a horse turns, whether there be a wooden *pillar* therein, or not.

There are also *pillars* in manages on the circumference, or side, placed at certain distances, by two and two. To distinguish these from that of the centre, they are called the *two pillars*. When these latter are spoken of, it is usual to say, *to set the horse between the two pillars*. When the former, it is called, *Working round the pillar*.

The use of the *pillar* in the centre is for regulating the extent of the ground, that the manege upon the volts may be performed with method and fullness, and that they may work in a square, by rule and measure, upon the four lines of the volts; and also to break unruly high-mettled horses, without endangering the rider.

The *two pillars* are placed at the distance of two or three paces one from the other. The horse is put between these, to teach him to rise before, and work out behind, and put himself upon raised airs, &c. either by the aids, or chastisement.

It has been supposed, that the hint of using *pillars* in the manege was taken from a contrivance of Eumenes; who, as Plutarch relates it, being besieged at the fort of Nora, by Antigonus, and fearing lest his horses should suffer for want of action, contrived a method of working them, without removing them from their stalls. For this purpose he placed a pulley over their heads in the beams of the stables, with which, by means of running reins, he pulled up their fore-parts, causing at the same time people to stand behind them, who, urging and lashing them with whips, put them into motion, made them yerk out behind, raising and moving their fore-legs, and work and chafe themselves till they sweat copiously; by these means he preserved their health, kept them in wind, and ready for service. The single *pillars*, once so frequent in manages, but now laid aside, was first used in Naples, and owes its origin to the want of covered buildings for riding and breaking horses: in lieu of which they dug trenches, for working their horses; the sides of the trenches supplying the want of walls, and producing in a certain degree the same effect. The famous Pignatelli, of Naples, having no covered manege, worked his horses in the open air, and used to tie them to a tree and work them round it. Pluvinel, of France, was one of his scholars; and returning to France, where he professed horsemanship, he placed a post or *pillar* in his manege, in imitation of Pignatelli's tree, and made the same use of it as to that he soon added another of the same size and height; which two *pillars* were calculated to answer purposes different from those for which the single *pillar* had been erected: the two *pillars* are still in use, and reckoned an essential piece of furniture in all riding-houses.

The single *pillar* has been long discontinued, but may be employed to advantage upon certain occasions; especially where a horseman undertakes to *train* a horse, without the assistance of another person. It should be observed that no horse ought to be put between the two *pillars* till he is well supple, and has acquired the first principles of the union between the legs, which are the natural *pillars* that every horseman should employ. The horse should be gently worked at first, that he may not become furious, and he should be made to go only from side to side by means of the bridle, or from fear of the chambrette. In a few days, when he is accustomed to the subjection of the *pillars*, try to make him insensibly go into the croupade, and endeavour to get from him a step or two at first, and in time of the *pesade* or *passade*.

The worst effect of the *pillars* is the hazard you run of entirely ruining the backs of your horse, if you do not adjust his ears exactly between their parts and the haunches. Boyer's Hist. and Art of Horsemanship, vol. ii. p. 60, and 164, &c.

PILLARS, *rules of*. See RULE.

PILLE *of Feathers*, or PILE *Feathers*, in the county of Lancaster, a defence built on a creek of the sea, called *Pille*, by the whole of the county, for a *pile*, or fort, built for the safeguard or protection of any place.

This *pille* was erected there by the abbot of Fountenille, in the 33d year of *Edward* III. Camd. Brit. *Ex—dominus Henricus comitis Northumbriæ inquisitus, super pelam, & dominium de Man, &c.* Rot. Pat. 1 Hen. IV.

PILLORY was anciently a post erected in a cross road, by the lord, as a mark of his supremacy, with his arms on it, and sometimes with a collar to tie criminals to.

PILLORY, at present, is a wooden machine, wherein certain criminals, as perjurers, &c. are fastened, and exposed to the public derision.

With us it is in the form of a frame erected on a pillar, and made with holes and folding boards, through which the heads and hands of criminals are put.

The etymology of this word has been variously assigned by different writers: Spelman derives it from the French *pilorin*, *speculator*; Cowel from *pyx*, *janua*, and *ium*, *calx*; but the etymology of Du-Cange is the most probable, who derives it from *pila*, a *pillar*.

In the laws of Canute it is called *croftbrug*. Sir Henry Spelman says, it is *supplicii genus ad ludibrium, nostris quam parum*. It was peculiarly intended for the punishment of bakers who should be caught guilty in the weight, or fineness of their bread. In old charters it is called *collistrigium*.

The *pillory* in Paris is in the middle of a round tower, with openings on every side. It is ascended on an axis, or arbour; round which the executioner gives the criminal the number of turns appointed in court; stopping him at each opening, to shew him to the people. It was intended for several kinds of criminals, particularly for fraudulent bankrupts; and all those who made a cession, or surrender, of their effects to their creditors, were obliged to take some turns round the *pillory* on foot, with a green cap on.

PILLOW *of a plough*, a term used by the farmers to express that part of a *plough* which serves to raise or sink the coulter, and with it the share, in the land is to be *ploughed* shallower or deeper.

This *pillow* is a cross piece of wood, reaching from one of the cross-pieces, or uprights, to the other; and as they are bored with two rows of holes, this *pillow* can be flipped up or down to any height, and kept there by pegs or cords in the holes. See PLOUGH.

PILLOW, in a *ship*, is that piece of timber whereon the bow-sprit rests at its coming out of the hull aloft, close by the fore.

PILLVENKEGEN, in *Ornithology*, the name of a bird approaching to the snipe kind: described by Aldrovand, and supposed by some to be the bird we call the KNOT.

PILOSE *leaf*, among *botanists*. See LEAF.

PILOSELLA, in *Botany*, *creeping mouse-ear*. See HAWKWEED.

PILOT, the person who superintends the navigation of a ship, either upon the sea-coast, or on the main ocean; but it is more particularly applied to a person retained on board a ship to conduct it into a road, or harbour, or over bars or sands; or through serpentine and intricate channels, or the like.

Menage derives the word *pilot* from *πηδὸν* i. q. *οἰακὸν*, he who governs the prow, or head. Others fetch it from the old French *pile*, a *ship*.

Pilots are no constant and standing officers on board our vessels; but are mostly called in occasionally, on coasts and shores unknown to the master. And, having done their parts in piloting the vessel, they return to shore, where they reside.

The regulations, with regard to *pilots* in the royal navy, are as follow: the commanders of the king's ships, in order to give all reasonable encouragement to so useful a body of men as *pilots*, and to remove all their objections to his majesty's service, are strictly charged to treat them with good usage, and in equal respect with warrant-officers.

The purser of the ship is always to have a set of bedding provided on board for the *pilots*, and the captain is to order the boatswain to supply th[illegible] convenient place to lie in near [illegible] the common men; which bedd[illegible] be returned when the *pilots* le[illegible]

A *pilot*, when conducting [illegible] *pilot*-water, shall have the [illegible] the ship, and may give orders [illegible] ming, or furling the sails, [illegible] concerns the navigation; and [illegible] that all the officers and crew [illegible] captain is diligently to obey [illegible] and if he judges him to be [illegible]

into danger, he may remove him from the command and charge of the ship, and take such methods for her preservation as shall be judged necessary; notwithstanding the log-book the exact hour and time when the *pilot* was removed from his office, and the reasons assigned for it.

Captains of the king's ships, employing *pilots* in foreign parts of his majesty's dominions, shall, after performance of the service, give a certificate thereof to the *pilot*, which being produced to the proper naval officer, he shall cause the same to be immediately paid; but if there be no naval officer there, the captain of his majesty's ship shall pay him, and send the proper vouchers, with his bill, to the navy-board, in order to be paid as bills of exchange.

Captains of his majesty's ships, employing foreign *pilots*, to carry the ships they command into, or out of foreign ports, shall pay them the rates due by the establishment or custom of the country, before they discharge them; whose accounts being duly vouched, and sent with a certificate of the service performed, to the navy-board, they shall cause them to be paid with the same exactness as they do bills of exchange. Regulations and Instructions of the Sea Service, &c.

Pilots of ships taking upon them to conduct any ship from Dover, &c. to any place up the river Thames, are to be first examined and approved by the master and wardens of the Trinity-house, &c. or shall forfeit 20*l.* for the first offence, 40*l.* for the second, and 40*l.* for every other offence; one moiety to the informer, the other to the master and wardens; but any master or mate of a ship may *pilot* his own vessel up the river: and if any ship be lost through the negligence of any *pilot*, he shall be for ever afterwards disabled to act as a *pilot*. 3 Geo. I. cap. 13.

The lord wardens of the cinque-ports may also make rules for the government of *pilots*, and order a sufficient number to ply at sea to conduct ships up the Thames. 7 Geo. I. cap. 21.

No person shall act as a *pilot* on the Thames, &c. (except in collier ships) without licence from the master and wardens of Trinity-house, at Deptford, on pain of forfeiting 20*l.* *Pilots* are to be subject to the government of that corporation, and pay ancient dues not exceeding 1*l.* in the pound out of wages for the use of the poor thereof. 5 Geo. II. cap. 20. In charter parties of affreightment, the master generally covenants to find a *pilot*, and the merchant to pay him: and in case the ship shall miscarry through the insufficiency of the *pilot*, the merchant may charge either the master or the *pilot*; and if he charges the master, such master must have his remedy against the *pilot*. Lex Mercatoria, 360.

Among the French *pilots* also used for afterermost, or an officer on board a ship, who always watches her course, and directs it.

There are among the French two kinds of *pilots*; the one a coasting *pilot*, well acquainted with the coasts, ports, roads, bars, sands, &c. and who commands in sight thereof.

The other an officer who makes observations, and takes altitudes out at sea; uses the quadrant and fore-staff; and also watches the compass.

The *pilot* is always the second person in the ship, whether it be a man of war, or merchant-man. In the former the captain is the first, the *pilot* the second. In a merchant-ship, the master is the first, the *pilot* after him.

The *pilot* is also the steersman, who stands at the helm, and manages the rudder.

PILOTING, in *Navigation*, is either common or proper: common *piloting* is that art which consists in coasting along shore, or sailing within sight of land. Proper *piloting* is the art of sailing to distant places through the ocean, and out of sight of land. See Navigation, Pilot, and Sailing.

PIMENTA, *pepper-tree*, in *Botany*, the name of a very remarkable little plant, of which Mr. Bernard de Jussieu has given a very accurate account in the Memoirs of the Academy of Sciences of Paris, 1739. See *Tab.* XV. *Botany*, N° 121.

This is a genus of plants in the *icosandria* class of ferns in the Linnæan system: the characters of which are, that the male flowers are numerous, and stand on the sides of the leaves; and the female part of the fructification has no cup or petals, but consists of a round quadricapsular fruit, which contains a vast number of roundish seeds.

PILUM, in *Roman Antiquity*, a missive weapon, which in charging they darted against the enemy. It was commonly a four-square, sometimes round, compounded of a piece of wood three cubits long, and a flip of iron of the same length, looked and jagged at the end.

PILY *stone*; see Early *Tide*.

PIMENTO, in *Botany*, all *spices*, or *Jamaica* Pepper. Miller ranks these species under the genus of *caryophyllus*, or clove-*tree*; but Linnæus makes it a species of the *myrtus* or myrtle.

It grows on the hilly parts of Jamaica, and is much cultivated there; because of the great profit from the cured fruit sent in great quantities yearly into Europe.

It flowers in June, July, and August, sooner or later, according to its situation and the different scasons for rain; and after it flowers, the fruit soon ripens.

There is little difficulty in curing and preserving this fruit for use, which is done thus: the Negroes climb the trees and pull off the twigs with the unripe green fruit, and afterwards carefully separate the fruit from the twigs, leaves, and ripe berries; which done, they expose them to the sun from its rising to setting, for many days, spreading them thin on cloths, turning them now and then, and carefully avoiding the dews. By this management they become a little rugose or wrinkled, dry, and from a green change to a brown colour, and then they are fit for the market.

The ripe berries are very carefully separated from those to be cured; because their wet and plentious pulp renders them unfit for cure. See *Jamaica* Pepper.

It is accounted the best and most temperate, mild, and innocent, of common spices, and fit to come into greater use, and to gain more ground than it hath yet done. It surpasses most of the East Indian aromatics in promoting the digestion of meat, attenuating tough humours, moderately heating, strengthening the stomach, expelling wind, and doing those friendly offices to the bowels we generally expect from spices. Phil. Trans. N° 192.

Distilled with water, it yields an elegant essential oil, so ponderous as to sink in water, in taste moderately pungent, in smell and flavour approaching to oil of cloves, or a mixture of those of cloves and nutmegs: the remaining decoction, infusitated, leaves an extract somewhat ungrateful but not pungent. Rectified spirit is impure, by maceration or digestion, the whole of its virtue, together with a brownish-green tincture. The college of London directs a simple water to be distilled from this spice, in the proportion of a gallon from half a pound; and a spirituous water, by drawing off two or three gallons of proof spirit from the same quantity of the spice. Lewis.

PIMP-*tenure*, a kind of *tenure* mentioned in our old writers. *Willielmus Heppestort, tenet dimidiam virgatam terræ, per servitium custodiendi fen damoiselles fcil. meretrices, ad usum omnium Regis.* 12 Ed. I.

PIMPERNEL, *anagallis*, in *Botany*, a genus of the *pentandria monogynia* class. Its characters are these: the flower hath an empalement, which is cut into five sharp segments; the flower is of one leaf, spread open, and cut into five parts; the germen afterwards becomes a globular vessel with one cell, opening horizontally, in which are lodged several angular seeds. There are four species.

Pimpernel, is a plant moderately warm and dry, with a little stypticity; and is therefore accounted by some a good vulnerary. The juice being given inwardly by itself, or mixed with cow's milk, is useful in consumptions, and distempers of the lungs; it is often put in cordial waters as an alexipharmic, and is good against malignant distempers. It has been recommended by some writers of note as of singular advantage in maniacal cases, and in delirious fevers. James.

Lewis observes, that the leaves of the *pimpernel* are not wholly destitute of medicinal powers, for the expressed juice, on being depurated by settling, and then inspissated to the consistence of an extract, affects the organs of taste with a pungent saline austerity: so that they have some claim to the resolvent and detergent virtues ascribed to them by some writers; though neither a decoction nor tincture of them, nor their juice in its dilute state, and much less their distilled water, can exert those virtues in any considerable degree.

Pimpernel, *water*, a species of *veronica*, or speedwell. See Brook-lime.

Pimpernel, *round-leaved water*. See Samolus.

Pimpernel, *yellow, of the woods*. See Loose-strife.

PIMPILIM, in *Botany*, a name by which some authors have called the plant which produces the long pepper, used in medicine.

PIMPILLO, in *Botany*. See *Prickly* Pear.

PIMPINELLA. See *Burnet* Saxifrage.

PIMPLE, in *Medicine*, a small pustule arising on the face. By mixing equal quantities of the juice of hare's-leek, *fennel water*, passed through paper, and of spirit of wine rectified by itself, a white coagulum of a very volatile nature is formed; which Dr. Borghart commends for curing *pimples* of the face; and says, that the thin liquor separated from it, with sugar-candy, is an excellent remedy for thick viscid phlegm in the mouth. Satyr. Silefiac. Spec. 4. Ob. 2.

PIN, in *Commerce*, a little necessary implement, chiefly used by the women in adjusting their dress.

The form and application of this little moveable need no description; but its consumption, and the number of hands it employs are too considerable to be passed by unnoticed.

Pins are now altogether made of brass-wire, blanched; formerly they likewise made them of iron-wire, which being blanched, like the others, passed for brass: but the ill effects of these *pins* has quite discarded their use. The French, however, could not be driven off from them without several arrets of parliament. By a sentence of the lieutenant de police, July 1673, the tenants of some millions of those *pins* was confirmed, and the *pins* condemned to be burnt by the common executioner.

The *pins* most esteemed in commerce are those of England; those of Bourbonnois are next; then those made at Rogle, Nangle, and some places in Normandy.

The perfection of *pins* consists in the fineness of the wire, and its blanching; in the heads being well turned, and the points filed.

The London pointing and blanching are in most repute; because our *pin*-makers in pointing use two steel mills, the fall of which forms the point, and the latter takes off all irregularities, and renders it smooth, and as it were polished; and, in blanching, use block tin, granulated; whereas in other parts they use a mixture of tin, lead, and quicksilver; which not only blanches worse than the former, but is also dangerous, on account of the ill quality of that mixture, which renders a puncture with a pin thus blanched very difficult to be cured.

The consumption of *pins*, and the number of artificers employed in the manufacture thereof, are incredible. In Paris alone there were anciently above one thousand people employed in it; at present there are none; yet there is every year sold above fifty-thousand crowns worth of the *pin-wire* to the *pin*-makers of the neighbouring places, all brought thither from Buckholm. In the little town of Rogle, in Normandy, there are computed at least five-hundred workmen employed in the *pin* manufacture; the whole town being peopled therewith.

Notwithstanding that there is scarce any commodity cheaper than *pins*, there is none that passes through more hands before they come to be sold. They reckon twenty-five workmen successively employed in each *pin*, between the drawing of the brass-wire, and the sticking of the *pin* in the paper.

Pins are distinguished by numeros; the smaller called from N° 3, 4, 5, thence to the 14th; whence they are only accounted by two to two, viz. N° 16, 18, and 20, which is the largest size.

Besides the white *pins*, there are also black ones made for mourning, from N° 4, to N° 16. These are usually of iron-wire.

Lastly, there are *pins* with double heads, of several numeros; used by the ladies to fix the buckles of their hair for the night, without danger of being disturbed by their pricking, &c.

The first mention of *pins* that occurs in the English statute-book is found in a statute of Richard III. in 1483, prohibiting foreign manufactures; and it appears from the manner in which *pins* are described in a statute of the 34th and 35th of Henry VIII. cap. 6. (A. D. 1543) and the labour and time which the manufacture of them would require, that they were a new invention in this country, and probably but lately brought from France. However, in about three years time they fell into the present ingenious and expeditious manner of making them. One of the articles of the statutes of the ancient *pin*-makers of Paris was, that no master should open more than one shop for the sale of his wares, except on new-year's day, and the eve thereof; this we mention in an age of luxury and profusion, to recollect the agreeable simplicity of our forefathers, who contented themselves with giving *pins* for new-year's gifts.

Hence the custom of still giving the name *pins*, or *pin-money*, to certain presents, which accompany the most considerable bargains; in which it is usual to give something towards the *pins* of the wife, or children, of the person with whom the bargain is struck.

PIN, *bird*. See HOOK.

PIN, *painting*. See PROTRACTING.

PIN-*money*, the name given to that allowance usually made by the husband to his wife, for her own spending.

All PINNERS *before*, a method of drinking anciently used among the Danes in England. The custom was, to fix a pin in the side of the wooden cup or wassail-bowl; which no wash guest was to drink below, upon penalty of forfeiting.

PIN *and web*, a horny induration of the membranes of the eye, not much unlike a cataract.

The *pin* and *web* is the same with what we otherwise call PANNUS, UNGUIS, STAPHYLOMA, &c.

PIN-*wheel of a clock*, the same with the striking-wheel. See WHEEL and CLOCK.

PINACOTHECA, among the *Ancients*, a place where pictures, statues, and other curiosities were kept.

PINACIA, Πινακια, among the Athenians, tablets of brass, whereon the names of all the persons in each tribe duly qualified, and willing to be judges or senators of the areopagus, being severally written, they were cast into a vessel provided on purpose, and into another vessel were cast the same number of beans, a hundred of which were white, and all the rest black; then the names of the candidates and the beans were drawn, one by one; and those whose names were drawn out together with the white beans, were received into the senate. See PROBULEUMA.

In Solon's time there were only four tribes, each of which elected a hundred senators; so that the areopagus consisted of four hundred members; but the number of tribes being afterwards increased, the number of senators was consequently augmented by some hundreds; but the manner of election remained the same. See ARROPAGUS.

PINARII, among the Romans, an order of priests belonging to Hercules, who offered sacrifices to that god in a solemn manner every year. They were in this service connected with the POTITII.

PINASTELLA, in *Botany*. See HIPPURIS.

PINASTER, in *Botany*. See PINE.

PINCH, in *Music*, a kind of grace proper for certain instruments, particularly the harpsichord. It is formed by striking alternately the sound of the written note with the sound of the inferior note, and observing to begin and finish with the note which bears the *pinch*. The difference between the *pinch* and TRILL is this, that the latter is struck with the superior note, and the *pinch* with the inferior.

To PINCH, is to use the fingers, instead of the bow, to make the chords of an instrument sound. There are some chord instruments which have no bow, and which are played only by *pinching*, as the lute, guittar, &c. and sometimes those with which the bow is generally used are pinched, as the violin and violoncello; and this method of playing is marked in the Italian by the word *pizzicato*.

PINCHBECK. See GOLD-*coloured metal*.

PINCHING, in *Gardening*, a sort of pruning, performed by nipping or breaking off the branches or sprigs of a plant, or tree, between the nails of two fingers.

Most gardeners hold, that *pinching* contributes to the abundance of the fruit, as well as of the branches; and they say, that young shoots, thus lopped, are less apt to grow black and die, than when cut with a pruning-knife.

The season for *pinching* is chiefly in April or May; sometimes it is also practised in June and July. The fruits, it is practised on, are chiefly melons, cucumbers, &c. Quantity also prescribes it for fruit-trees.

It is chiefly to be practised on the large branches towards the top of the plant, or tree, which are useless, and yet consume a great quantity of good sap. It must rarely be employed on the large branches below; which ought always to be preserved for the winter's pruning, that they may yield others the following year, fit to fill the empty places. Nor must the operation of *pinching* be performed on the tender shoots; because, having only just sap enough for themselves, when they come to put forth more branches in the place where they are *pinched*, the small flock of sap allotted them, being divided, will starve them. The operation is to be performed within two or three eyes of the branch they grow out of.

The effect of *pinching* is, that, instead of one useless, and, perhaps hurtful wood-branch, a vigorous tree will put forth two or three at the eyes remaining; and the sap being thus divided, the branches will be less, and fit for both wood and fruit.

PINCHING, in the *Manege*, is when the horse, handling, the rider holds him fast with the bridle-hand, and applies the spurs just to the hairs of the sides, without pricking him.

If the horse is impatient under the spur, and draws himself up, and wants to go forward, this is a sign of vigour and mettle. But the purchaser must [illegible] on the horse's back; for the [illegible] ing the dullest horse seem to [illegible]

The purchaser must also diffinguish between [illegible] ons of the horse under this [illegible] vigour, and that which arises from [illegible] lith, and which goes off immediately.

Pinching is accounted an aid, [illegible] correction.

PINDARIC, in *Poetry*, an ode formed [illegible] manner of Pindar.

The *Pindaric* manner is distinguished by the [illegible] and length

height of the flights, the suddenness and surprizingness of the transitions, and the seeming irregularity, wildness, and enthusiasm, of the whole.

Pindar, whence the manner takes its name, was of Thebes; he flourished about four hundred and seventy-eight years before Christ, and was contemporary with Æschylus. When Alexander the Great destroyed Thebes, he ordered the house in which Pindar had lived to be preserved. What we have remaining of his is a book of odes, all in praise of the victors at the Olympian, Pythian, Nemean, and Isthmian, games; wherefore the first is entitled, the *Olympian*; the second, the *Pythian*; the third, the *Nemean*; and the fourth, the *Isthmian*. Pindar is full of fire and fire: his thoughts are sententious, his style impetuous, his sallies daring, and frequently running, as it were, at random; he affects a beautiful disorder, which, yet, is said to be the effect of the greatest art.

The supposed irregularity of his numbers has made several of his imitators imagine themselves *Pindaric* poets, by the mere wildness and irregularity of their verses. None of our writers seem to have succeeded in the *Pindaric* character better than Cowley.

In a *Pindaric* ode, the plan of the whole ought to be drawn first, and the places marked out where the elegant sallies and wanderings may best be, and how the return may be justly made to the subject.

PINE, *pinus*, in *Botany*, a genus of the *monœcia adelphia* class. Its characters are these: the male flowers are collected in a scaly conical branch, without petals, having many stamina, which are connected at their base, terminated by erect summits, included in the scales, which supply the want of petals and empalement; the female flowers are collected in a common oval cone, and stand at a distance from the male on the same tree; under each scale of the cone are produced two flowers, which have no petals, but a small germen, supporting an awl-shaped style, crowned by a single stigma; the germen afterward becomes an oval, oblong nut, crowned with a wing, included in the rigid scale of the cone. Linnæus reckons twelve, and Miller fourteen species.

The *pine*-tree, with five rough leaves in each sheath, the commonly called lord Weymouth's *pine*, and the *pine* with small whitish cones, called the Scotch *pine* or fir, the wood of which is the red or yellow DEAL, are the best worth cultivating of all the kinds for the sake of the wood; the others may be planted for variety in parks, &c. where they make a good appearance in winter, when other trees are destitute of leaves.

All the sorts of *pines* are propagated by seeds, which are produced in hard woody cones; the way to get the seeds out of those cones which are close, is to lay them before a gentle fire, which will cause the cells to open, and then the seeds may be easily taken out. If the cones are kept entire, the seeds will remain good some years. The best time for sowing the seeds of *pines*, is about the end of March; when the seeds are sown, the place should be covered with nets to keep off birds, otherwise, when the plants begin to appear with the buds of the seed on their tops, the birds will pick off the heads of the plants, and destroy them.

When the plants appear, they must be constantly kept clean from weeds; and in every dry season, if they are now and then gently refreshed with water, it will forward their growth; but this must be done with great care and caution; for if they are hastily watered, it will wash the tender plants out of the ground, or lay them down flat, which often ruins their thanks; and when this is too often repeated, it will have the same effect. If the plants come up too close, they may be thinned about the beginning of July.

The best season to transplant all the sorts of *pines* is about the latter end of March, or the beginning of April, just before they begin to shoot; for although the Scotch *pine*, and some of the most hardy sorts, may be transplanted in winter, especially when they are growing in strong land, where they may be taken up with balls of earth to their roots; yet this is frequently attended with bad consequences; but those which are removed in the spring rarely fail.

When these trees are planted in exposed situations, they should be put pretty close together, that they may shelter each other; and when they have grown a few years, part of the plants may be cut down, to give room for the others to grow; but this must be gradually performed, for by too much opening the plantation at once, the air, by being let in among the remaining trees too freely, checks their growth.

As the upright growth of these trees renders their wood the more valuable, they should be left, as before observed, for coverts; by this means they will draw each other up, and grow very tall. If they are left eight feet asunder each way, it will be sufficient room for their growth.

The first distance of their planting being therefore about four feet, if at the first thinning a fourth part of the trees are taken away, the rest may stand twelve or fourteen years longer; by which time they will be of a size for making ladders and standards for scaffolding, besides many other purposes they will then answer; so that from this sale as much may be made, as will defray not only the whole expence of the planting, but the rent of the land, with interest; while the standing trees may remain for the fortunes of younger children.

From the wild *pine*, or pinaster, is procured the common turpentine, which is chiefly used by farriers; and from it is distilled the oil of turpentine. The finer and more valuable part, which comes first, is called the *spirit*; what is left at the bottom of the still is the common resin.

The kernels of the nuts of the manured or stone *pine*, are of a balsamic and nourishing nature; good for consumptions, coughs, and hoarseness, restorative, and of service after long illness. Miller's Gard. Dict.

The leaves and tender tops of *pine* and FIR are used for diet-drinks, and allowed to be antiscorbutic and diuretic. See CROWBERRY.

The resinous exudations of *pines* and firs are an important branch in the materia medica, and not only useful in the prescriptions of physicians, but have also been thought otherwise conducive to health. Pliny tells us, that wines, in the time of the old Romans, were medicated with pitch and resin. And Josephus, in his Dendrographia, observes, that it is wholesome to walk in groves of *pine*-trees, which impregnate the air with balsamic particles. It is known that all turpentines and resins are good for the lungs, against gravel also, and obstructions; and it is said, that the medicinal properties of those drugs are found in TAR-water, which operate without heating the blood, or disordering the stomach.

Pitch, tar, rosin, and turpentine, are all made from these trees by a very familiar process. In the spring time, when the sap is most free in running, they pare off the bark of the *pine*-tree, to make the tap run down into a hole which they cut at the bottom to receive it; in the way, as it runs down, it leaves a white matter like cream, but a little thicker: this is very different from all the kinds of resin and turpentine in use, and it is generally sold to be used in the making of flambeaux, instead of white bees-wax. The matter that is received in the hole at the bottom, is taken up with ladles, and put into a large bucket; a great part of this immediately runs through, and this is the common turpentine. This is received into stone or earthen pots, and is ready for sale. The thicker matter, which remains in the bucket, they put into a common alembic, and adding a large quantity of water, they distil this so long as any oil is seen swimming upon the water: this oil they separate from the surface in large quantities, and this is the common oil or spirit of turpentine; the remaining matter at the bottom of the still is common yellow resin. When they have thus obtained all that they can from the tap of the tree, they cut it down, and hewing the wood into billets, they fill a pit dug in the earth with these billets; and setting them on fire, there runs from them, while they are burning, a black thick matter: this naturally falls to the bottom of the pit, and this is the tar. The top of the pit is covered with tiles, to keep in the heat; and there is at the bottom a little hole, out of which the tar runs like oil: if this hole be made too large, it lets the whole quantity of the tar on fire; but if small enough, it runs quietly out.

The tar, being thus made, is put up in barrels; and if it be to be made into pitch, they put it into large boiling vessels, without adding any thing to it; it is then suffered to boil a while, and being then let out, is found, when cold, to be what we call pitch. Phil. Trans. N° 203. p. 191.

PINE, *ground*, in *Botany*, a species of ORTHANDER.

PINE, *sinking ground*. See CARTHUSIONWA.

PINE, *heath*, *tree*. See CORIS.

PINE, *tree*, in *Botany*. A branch of this tree being brought from the Cape of Good Hope, by Mr. Goddard, and presented to the Royal Society, Dr. Sloane gave the following account of it: the twig of this tree had a great many leaves set round it, very close to one another, so as to hide the twig itself there where they grew; each of the largest being about four inches long, and three quarters of an inch broad in the middle where broadest, from whence they decrease towards both extremes, ending in a point; being like those of the osier willow, only broader, and all covered over with the thickest, finest, and longest, white silken hair, or down, of any plant the doctor remembers to have seen. The cones are of the bigness of those of the cedars of Lebanon, and

of

of the same shape; the calicles, or small scales of each scale, being covered over with a white short down or wool, shining also like silk. Between the scales is lodged the seed, which is about as large as the pine nut, near the same shape, of a dark brown colour, and having a rising eminent line or bolt running through the middle of it from end to end. This seed has a shining, reddish brown membrane, which has on its top four feathers, like those belonging to the seed of the clematitis; which being between the leaves, and rising above them, adds a very great beauty to the cone, and may in some degree be serviceable, by means of the wind, to loosen or carry the seed to distant places, thereby propagating itself. Dr. Plukenet calls it *tuberosum*. Phil. Trans. N° 198.

PINE, *spunge leaved*, in *Botany*. A branch of this tree being brought from the Cape of Good Hope by Mr. Goddard, and presented to the Royal Society, Dr. Sherard gave the following description of it: The bark was of a brown colour and smooth; the wood white and hard, with only a small pith; the leaves were round, without any order, very thick set, having no foot-stalks; being about two inches and a half long, and about one-third of an inch broad near the farther ends, where broadest; smooth, hard, and of a brownish or grey green colour; on the top of the branch comes the fruit, which is surrounded by three or four twigs overtopping it, and with their leaves almost hid in it; it is about five inches long, and is made up of many scales, hard and red, including one another; the lowermost and outermost being very short, the uppermost four inches long, each of them ending in a point; some scales having on their outsides a gummy piece. In the middle of these scales were the first rudiments of many seeds, the same not being fully ripe; each of which is fit about with a great quantity of yellow, fine, flaxen down, about three quarters of an inch long, having a fistula, or string, two inches long, each of all membranes inclosing the fistula and tomentum; being scattered at top for their better dispersion, in order to propagate themselves. Phil. Trans. N° 198.

PINE, wild. See TENGHIN.

PINE-*apple*, a delicious fruit, called by authors ANANAS. In the Linnæan system, this is a species of the BROMELIA; to which it has also added the EANATAS, making that genus include seven species. Its botanical characters are these: the flower consists of three oval petals, produced from the protuberance of the pyramidal fruit, which have its awl-shaped stamina, crowned with spear-shaped summits; the germen is situated below the flower, which becomes a cell, in which are lodged several angular seeds. Miller enumerates six varieties; and probably there might, by proper management in the sowing, be raised as many as we have of apples and pears in our orchards.

The fruit is produced from an herbaceous plant, which has leaves resembling those of aloe, and, for the most part, fawned on their edges, but much thinner, and not so juicy as the aloe; the fruit resembles the cones of the pine-tree, whence it is supposed to have its name.

The plant grows wild in vast abundance in many parts of Africa, and has been long cultivated in the better islands of the West Indies, where they are now very plentiful and very fine. It is now long since it has been introduced into the gardens of Europe; where, with proper management, it succeeds very well. There is, in my opinion, but three are more varied to good from the American plants, as from thole originally propagated by M. le Cour of Leyden; the firſt who ever ſucceeded in the bringing it to fruit in Europe; but this is an error, occasioned by ſome of the inſidierant Iſlands having been at firſt frequently ſent over from America; but of late we have had much finer from thence than ever Dr. le Cour knew.

The firſt ſort, or the oval ſhaped *pine-apple*, with a whitiſh flelh, is the moſt common in Europe; but the ſecond, or pyramidal *pine-apple*, with a yellowiſh flelh, called the ſugar-loaf *pine*, is greatly preferable to it, being much larger and better flavoured, and the juice being leſs ſtringent, the fruit may be eaten with leſs danger in large quantities. This uſually produces fix or ſeven ſuckers alſo under the fruit, from whence it may be propagated, and therefore is the moſt to be eſteemed of any. The third ſort, or pine-apple with ſmooth leaves, is propagated merely as a curioſity, the fruit being much inferior to that of the others. The fourth ſort, or green pine-apple, is the moſt tender of all, and is had from Barbadoes and Montſerrat. The fifth, or that with very ſmooth grafs-green leaves, is what is uſually brought from the Caſtor. Theſe plants are propagated by planting the crowns or ſuckers: theſe, after having been two days in a warming pot or hot place, are to be ſet in pots of five or ſix inches over at the top, filled with good freſh light earth, mixed with a little rotten dung; this mixture muſt be often turned, for eight or ten months, to make it mix the more perfectly. The moſt proper compoſt mould for the pine plant, ſays Mr. Speechly, is prepared by paring off the turf of a paſture, where the ſoil is a ſtrong rich loam, and of a reddiſh colour, about two inches thick; and laying it with the grafs ſide downwards, and one courſe thick in the pens of ſheep-paſtures, where it may continue two, three, or more months, being enriched by their urine and dung, and reduced by the treading of their feet. When it has lain in the pens till the quantity of ſheep's dung conſtitutes about one-third part, it may be laid in a heap for at leaſt ſix months, being often turned in that time: three wheel-barrows of this mill, one barrow of vegetable mould from decayed oak-leaves, and half a barrow of coarſe ſand, make a compoſt mould for crowns, ſuckers, and young plants. Three wheel-barrows of the above earth, two barrows of vegetable mould, one of coarſe ſand, and one-fourth of a barrow of ſoot, make a compoſt mould for fruiting plants. The plants, when ſet, muſt have a little water, to ſettle the earth to their roots; and the pot when plunged into a well-tempered bed of tanner's bark. See HOT-BED.

In the ſummer ſeaſon they ſhould be gently watered about twice in a week; and once a week over their leaves, in order to waſh the filth from them, and to promote the growth of the plants. Some perſons frequently ſhift their plants from pot to pot; but it is not adviſable to remove them oftener than twice in a ſeaſon; firſt about the end of April, and again in the beginning of Auguſt. At each of theſe times the bark-bed ſhould be ſtirred, and new bark added; and the plants, when they are plunged into it, ſhould be gently watered over their leaves. Here they may remain till the beginning of November; and in the winter ſeaſon they ſhould not be watered more than once a week. Their plants which ſhew their fruit ſhould never be removed, becauſe ſhifting them at this period will ſtint their growth, and retard their ripening. It is now the practice of thoſe who are deſirous of propagating this fruit, to raiſe low ſtoves, with pits in them, for the bark-bed. Some build them with upright glaſſes in front, about four feet high, and ſloping glaſſes over them, which riſe about ſix feet high, ſo that there is juſt height enough for perſons to walk upright on the back-ſide of the bark-bed. Others make only one ſlope of glaſſes from the top of the ſtove down to the pits, which lies about ſix or eight inches above the bark-pit in the front of the ſtove; but this ſtove is ſubject to an inconvenience, as there is no walk in the front between the bark-pit and the glaſſes. One of theſe ſtoves, about twenty-five feet long in the clear, with the pit for the tan reaching from end to end, and ſix feet and a half wide, will contain about a hundred plants. But it will be neceſſary to have a bark-pit under a deep frame, in order to raiſe the young plants; in this bed the ſuckers, when they are taken from the old plants, and the crowns which come from the fruit, ſhould be plunged, ſo that this frame will ſerve to raiſe the young plants for ſupplying the ſtove. Theſe young plants, unleſs the frame is built with brick-work, and flues for warming the air, ſhould be removed, in October, into the ſtove. In the beginning of March, if there be no nurſery for them, they muſt be removed into the bark-bed, which ſhould be properly renewed before, that the tan may have acquired a proper heat; care muſt be taken, that it be not too hot, leſt the roots be ſcalded. Air ſhould be covered with mats, but no water allowed. It ſhould be allowed to the pots in the ſtove, in order to promote the magnitude of the fruit. When the fruit is ripe, the glaſſes ſhould be taken off in order to let out the ſteam of the bed, and to admit freſh air; and in the end of the ſame day, in very hot weather, it will be proper to ſhade the glaſſes with mats. During the ſummer ſeaſon, the plants muſt be frequently watered in ſmall quantities at a time, and in the warmeſt they muſt have free air admitted to them every day, from ten o'clock till four. In winter the heat of the ſtove is to be raiſed by a thermometer, which ſhould never be kept to a greater warmth than ſeven or ſix diviſions above temperate, inclined to be moiſt than in many other ſtoves to. Sometimes they will require watering only once a week. When the plants are headed may be taken off the fruit, from which they will readily grow; and in the ſame manner ſuckers may be taken off, which ſhould be done about the beginning of October. The bark-bed ſhould be renewed, and the remainder of the tan, to the third of the old, which will augment the heat of the bed. warmth till February, when it ſhould be ſ... and a half or two at one time, ſuch ſo as to keep the bed as much as it firſt was. The autumn ſuckers will be proper to ſet on the bed again; and the freſh tan, to renew the warmth of the bed, as before the front. At this time it will be proper ...

young plants, which are deſigned to produce fruit the following year; and the tan-bed, into which theſe are plunged, muſt be renewed, in order to forward their growth, that they may have ſtrength enough by autumn to produce good fruit. Thoſe plants, which ſhew their fruit early in February, will ripen about June; but the ſeaſon in which the fruit is in greateſt perfection is from the beginning of May to the end of September. The method of judging when the fruit is ripe is by the ſmell, and from obſervation; nor ſhould it remain ſo long before it is cut as to become ſoft to the touch, for it will become flat and dead; and it ſhould be cut early in the morning, laid in a cool but dry place, preſerving the ſtalk and crown upon it, and eaten the ſame day in which it is cut. That ſort with green fruit, if ſuffered to ripen well, is of an olive-colour; but the ſugar-loaf ſort is preferable, and is eaſily diſtinguiſhed from all the others, by the purple ſtripes on the inſide of its leaves. The fruit, when ripe, is of a paler colour than the others, inclining to ſtraw colour. This ſort was brought from Brazil to Jamaica. The next in goodneſs to this is the Montſerrat *pine*; the leaves of which are of a dark brown, inclining to purple on their inſide; and the protuberances of the fruit are larger and flatter than thoſe of the common ſort. Miller.

One of the principal obſtacles attending the culture of the *pine-apple* has been to deſtroy the inſects which infeſt it. Mr. Speechley, in a late treatiſe on this ſubject, has enumerated three ſpecies, viz. the brown turtle-inſect, or *coccus heſperidum* of Linnæus; the white ſcaly inſect; and the white mealy crimſon-tinged inſect. The methods that have been formerly in uſe for extirpating them have been to ſhift the plants into freſh pots, at the ſame time cleanſing their leaves and roots, which is uſually denominated a dreſſing. Decoctions made from tobacco, wormwood, walnut-leaves, henbane, and other herbs of a bitter or poiſonous quality, have alſo been generally uſed on this occaſion, to which ſome have added ſnuff, ſulphur, and pepper; but none of theſe are in their nature ſufficiently penetrating. And it is well known, that ſhifting and dreſſing the plants conſiderably retard their growth, and give them a ſickly appearance, eſpecially in their fruiting ſeaſon. He therefore recommends the following receipt: take one pound of quickſilver; put it into a glazed veſſel, with one gallon of boiling water; let it ſtand till it becomes cold, and pour off the water for uſe. Repeat this on the ſame quickſilver, till a ſufficient number of gallons is provided; then to every gallon of this mercurial water add ſix ounces of ſoft green ſoap, diſſolved in a portion of it; let the mixture be milk-warm when it is uſed; then tie the leaves of the large fixed plants together; take them out of the pots, and diveſt them of their leaves, and dip them wholly in the mixture for three minutes, and ſet them out in the open air to dry, with their roots downwards; in a few hours repeat the operation a ſecond time, having added one table-ſpoonful of ſweet oil to every gallon of the mixture; then ſet them to dry, with their tops downwards, and afterwards remove them to the hot-houſe. The moſt eligible ſeaſons are March and September.

The ſame writer has alſo deſcribed a method of raiſing *pines* without the uſe of tanner's bark, or, at moſt, with only a covering of tan two inches thick, viz. by oak-leaves, collected in the fall of the year, laid in heaps ſix or ſeven feet thick to couch, well trodden, and occaſionally moiſtened, for five or ſix weeks, which, he ſays, are ſuperior to bark for this uſe. See Dr. Hunter's edition of Evelyn's Silva, 1776.

A ſimilar idea of uſing the decayed leaves of trees in the hot-houſe was before ſuggeſted by Mr. Clark of Chiſwick, and applied to the culture of melons. It appears, that leaves under proper management, i. e. after fermentation, &c. are a moſt valuable manure; mixed with dung they make the beſt hot-beds, which preſerve their heat much longer than thoſe which are made entirely with dung. Beſides, when reduced to black vegetable mould, and mixed with compoſt of earth, they are ſuperior to every other for flowers, as well as for all plants that grow in pots.

William Baſtard, eſq. has deſcribed a method of raiſing *pine-apples* in water. The plant contained in a pot of earth is placed in a pan, which is always kept full of water, and which, ſtands on a ſhelf near the higheſt, and conſequently the moſt heated, part of the back-wall of the hot-houſe, ſo that the *pine* plants ſtand as near as poſſible to the glaſs, without abſolutely touching it. The fruit raiſed in this manner is ſaid to be always much larger, as well as better flavoured, than when it is ripened in a bark-bed. Phil. Tranſ. vol. lxvii. part ii. art. 7.

PINE-*cake*, in *Metallurgy*, a word uſed to expreſs a ſort of mould, uſed in the refining ſilver. It has this name from its ſhape, reſembling the fruit of that name.

When the refiners have taken the mixture of the ſilver and mercury together out of the cauldron, and ſtrained it through two courſe wetted cloths, to make it the thicker, they then beat it with a fort of battledores, to drive out yet more of the quickſilver; and ſtraining it again after this, they take out the remaining thick amalgam, and forming it into little pellets, they put theſe carefully into the moulds called *pine-apples*, preſſing them down. The amalgam, when put into this veſſel or mould, is uſually ſo rich as to be about one fifth ſilver. The manner of diveſting this of the quickſilver afterwards is by means of fire; in which the quickſilver riſes in vapour, and the ſilver is left pure behind; but the careleſneſs of the workmen in doing this, and particularly the uſing bad veſſels, or the not luting them cloſe, cauſes a waſte of this mineral greater than could be conceived. Alcoſo tells us, that in the city of Potoſi alone, at the time of his writing, when the trading in metals ran but low, above thirty thouſand pieces of eight were waſted in quickſilver that was loſt one year with another. To prevent this, they then principally ſtudied the means of keeping the ſilver as dry of quickſilver as they could, in the *pine-apple*; but it then holding fourth-fifths of the whole maſs in quickſilver, the great waſte was in the ſeparating it afterwards.

PINE-*ſalt*, a name given to a preparation of the bark of the *pine*-tree, uſed as a ſort of ſeaſoning to food in the manner in which we uſe ſalt.

The Laplanders are very fond of this; and the manner of their preparing it is given in Scheffer's hiſtory of that country: they peel off the bark from the lower part of the bodies of thoſe trees, and ſeparating the outer rough part, they take the inner bark, which they carefully divide into its ſeveral thin coats; when they have thus reduced them to as thin pieces as they can, they expoſe them to the ſun in their ſummer months to dry, and when thoroughly dried, they tear them into thin and narrow ſlips, and put them up in boxes made of the outer bark of other trees freſh taken off. They bury theſe boxes in deep holes dug in the ſands, and let them remain thus one day; on the day following they bring together a number of ſtumps of trees, and other wood, and laying them over the place where the bark is buried, they ſet them on fire; the next day they take out their buried boxes, and the heat having penetrated ſo deep into the earth in a mild degree, the bark is found to have been greatly affected by it, and to have received a red colour, and a very agreeable flavour, ſomewhat ſweetiſh. This is their general ſauce; they eat it with all their food, as we do ſalt, but it has ſo little of the nature of ſalt, that the name is but ill adapted to it.

There is another vegetable ſubſtance, which, though of a diſagreeable taſte to us, yet cuſtom teaches them to be fond of. This is the angelica perroſa: they cut the large ſtalks of this plant before it runs to ſeed, and roaſt them; they eat this in conſiderable quantities with their *pine-ſalt*, and eſteem it not only an agreeable, but a more than ordinarily wholeſome ſort of food.

PINEA, or PIGNE, in *Commerce*, a term uſed in Peru and Chili, for a kind of light, porous maſſes, or lumps, formed of a mixture of mercury and ſilver-duſt from the mines.

The ore, or mineral, of ſilver, being dug out of the veins of the mine, is firſt broken, then ground in mills for the purpoſe, driven by water with iron peſtles, each of two hundred pounds weight. The mineral, thus pulverized, is next ſifted; then worked up, with water, into a paſte; which, when half dry, is cut into pieces, called *cuerpos*, a foot long, weighing each about two thouſand five hundred pounds.

Each cuerpo is kneaded up with ſea-ſalt, which, diſſolving, incorporates with it. They then add mercury, from ten to twenty pounds for each cuerpo, kneading the paſte afreſh until the mercury be incorporated therewith. This office, being exceedingly dangerous, on account of the noxious qualities of the mercury, is always made the lot of the poor Indians.

This amalgamation is continued for eight or nine days; and ſome add lime, lead, or tin ore, &c. to forward it; and, in ſome mines, they are obliged to uſe fire. To try whether or no the mixture and amalgamation be ſufficient, they waſh a piece in water; and if the mercury be white, it is a proof that it has had its effect; if black, it muſt be further worked.

When enough, it is ſent to the lavatories, which are large baſons that empty ſucceſſively into one another. The paſte, &c. being laid in the uppermoſt of theſe, the earth is then waſhed from it into the reſt by a rivulet turned upon it; an Indian, all the while, ſtirring it with his feet, and two other Indians doing the like in the other baſons.

When the water runs quite clear, out of the baſons, they find the mercury and ſilver, at bottom, incorporated.

This matter they call *pella*, and of this they form the *pinces*, by expreſſing as much of the mercury as they can; firſt, by putting it in woollen bags, and preſſing and beating it ſtrongly; then, by ſtamping it in a kind of wooden mould, of an octagonal form, at bottom whereof is a braſs plate pierced full of little holes.

The matter, being taken out of the mould, is laid on a trivet, under which is a large veſſel full of water; and the whole being covered with an earthen head, a fire is made around it.

The mercury ſtill remaining in the maſs is thus reduced into fumes, and, at length condenſing, it is precipitated into the water, leaving behind it a maſs of ſilver grains of different figures, which, only joining or touching at the extremes, render the matter very porous and light.

This, then, is the *pinca*, or *pigne*, which the workmen endeavour to ſell ſecretly to veſſels trading to the South Sea; and from which thoſe, who have ventured to engage in ſo dangerous a commerce, have made ſuch vaſt gains. Indeed, the traders herein muſt be very careful; for the Spaniſh miners are errant knaves, and to make the *pignes* weigh the more, they make a practice of filling the middle with ſand, or iron.

PINEAL, *pinealis*, in *Anatomy*, a name which Des Cartes gives to a ſmall gland, in the third ventricle of the brain, from its reſemblance to a pine-apple.

This gland he makes the ſenſorium, or ſeat of the reaſonable ſoul. Other authors call it *conoides* and CONARION.

PINEI *nuclei Malaccani ſive purgantes*, J. B. PINUS *Indica nucleo purgante* C. B. PINEI *nuclei Malaccani*. Park. in *Botany*, a ſpecies of the CROTON in the Linnæan ſyſtem. There grows, ſays Acoſta, in ſome gardens of Malabar, and alſo wild, in ſome woods, a tree of the bigneſs of a pear-tree, whoſe leaves are of a watry-green beneath, and of a deep green on the upper face, and are very tender and ſoft. They are of a very acrid taſte, and vellicate the tongue for a long while afterwards: the fruit is triangular, of the ſize of a filberd, and divided into many capſules, containing each a round ſort of white or dark greeniſh ſeed, equal to a pine-kernel, when taken out of its ſhell.

The Indians, as Acoſta ſays, take a couple of the kernels, peel them, and then pound them, and mix them in clyſters, againſt difficulty of urine, and the pain of the ſciatica; or exhibit them in cock-broth, for the evacuation of putrid, ſlimy, groſs, and cold humours, and particularly for the cure of an aſthma. They anoint the impetigo with thoſe kernels, bruiſed in water, and ſo cure it; but they are very burning. The cathartic pine-kernels, as Monardes ſays, purge very ſtrongly bile, phlegm, and water; and though milder than filberds, excite vomiting. When roaſted, they operate with leſs violence, and fewer gripes. They are exhibited in chronic diſeaſes, and have a peculiar virtue of evacuating groſs humours.

The fruit of this tree is the *grana tiglia* of other writers. It is intenſely hot and acrimonious; and ſo violent an evacuant, that it cannot be taken with any tolerable ſafety. This, as well as the PINHONES *Indici*, and AVELLANA *purgatrix*, which is a ſpecies of the JATROPHA, in the Linnæan ſyſtem, yield upon expreſſion a conſiderable quantity of oil, impregnated more or leſs with the taſte and purgative quality of the ſeeds; but they all appear too draſtic to be ventured on in ſubſtance. The wood and leaves of the plants are likewiſe ſtrong cathartics.

PINGUEDO, in *Anatomy*, the Latin term for FAT.

Some reſtrain *pinguedo* only to that *humid ſoft kind of fat* found in animals, next under the ſkin. See ADEPS.

PINHONES *Indici*, the name by which the Portugueſe call the purging nuts, as they are called, of America; the fruit of the JATROPHA *foliis cordatis angulatis* in the Linnæan ſyſtem, or the *ricinoides* and *curcas* of other writers. It is called Barbadoes nut; and has an oval, walnut-like fruit, with oblong black ſeeds. Their taſte is ſweetiſh, mucilaginous, and acrid; and they are powerful evacuants. In America it is ſaid to be taken in conſiderable quantities, and to purge without much inconvenience. See PINEI *nuclei*, &c.

PINGUICULA, in *Botany*. See BUTTER-*wort*.

It is ſaid, that the unctuous and glutinous juice of the *pinguicula* is uſed in ſome places as a liniment for chaps, and as a pomatum for the hair; that new milk, poured upon the freſh leaves, on a ſtrainer, and, after quick coagulature, ſet by for a day or two, becomes thick, tenacious, very agreeable, and ſalubrious, and throws off no whey, unleſs it be long kept; and that a little of the milk, to thicken it, ſerves for bringing freſh milk to the ſame ſtate; that a ſyrup made from the juice and decoctions of the leaves in broth, are uſed among the common people in Wales as cathartics; and that the herb is hurtful to cattle that feed upon it. Lewis.

2

PINGUIN, in *Ornithology*, is made a diſtinct genus of birds, of the order of web-footed, by Mr. Pennant; the characters of which are, that the bill is ſtrong, ſtraight, and bending a little towards the point; the tongue is covered with ſtrong ſharp ſpines, pointing backwards; the wings are very ſmall, pendulous, uſeleſs for flight, and covered with mere flat ſhafts; the body is covered with thick ſhort feathers, with broad ſhafts, placed as compactly as ſcales; the legs are ſhort and thick, placed quite behind; the toes are four, ſtanding forward, the interior looſe, the reſt webbed; and the tail is very ſtiff, conſiſting only of broad ſhafts. He has enumerated and deſcribed three ſpecies; viz. 1. The Patagonian *pinguin*, which inhabits an iſle near the Cape of Good Hope, on the coaſts of New Guinea, the iſle of Deſolation, ſouth to the Cape, the ſouthern parts of America, and the ſeas among the ice, as high as ſouth lat. 64° 12′, long 38° 14′ eaſt. It lives much at ſea; the wings act as fins; it burrows on land, and is analogous to ſeals. The name *pinguin* is given to theſe birds, he ſays, *propter pinguedinem*, on account of their fatneſs; and he obſerves, that it has been corrupted to *perguin*; ſo that ſome, imagining it to be a Welch word, ſignifying *white head*, entertained ſome hopes of tracing the Britiſh colony, ſaid to have migrated into America, under Madoc Gwineth, ſon of Owen Gwineth, A. D. 1170. But he adds, as the two ſpecies of birds that frequent that coaſt have black heads, we muſt reſign every hope, founded on that hypotheſis, of retrieving the Cambrian race in the new world. 2. The leſſer *pinguin*, *diomedea demerſa* of Linnæus, or *anſer Magellanicus* of Cluſius. See *Magellanic* GOOSE. And, 3. The red-footed *pinguin*, the PHAETON *æthereus* of Linnæus, inferior to the laſt in ſize, with a thick, arched, red bill; plumage like the former in texture; the head, hind part of the neck, and the back, of a duſky purpliſh hue, and breaſt and belly white; brown wings, with the tips of the larger feathers white; inſtead of a tail, a few black briſtles; and red legs. It is found on *Pinguin* iſle, near the Cape of Good Hope. Phil. Tranſ. vol. lviii. art. 14.

The PINGUIN is of a different genus from thoſe birds.

PINION, in *Mechanics*, an arbor, or ſpindle, in the body whereof are ſeveral notches, into which catch the teeth of a wheel that ſerves to turn it round.

Or a *pinion* is a leſſer wheel, which plays in the teeth of a larger. See WHEEL.

In a watch, &c. the notches of a *pinion* (which are commonly 4, 5, 6, 8, &c.) are called *leaves*, and not teeth, as in other wheels.

PINION *of report* is that *pinion*, in a watch, which is commonly fixed on the arbor of a great wheel, and which, in old watches, uſed to have but four leaves; it drives the dial-wheel, and carries about the hand.

The quotient, or number of turns, to be laid upon the *pinion* of report, is found by this proportion: as the beats in one turn of the great wheel are to the beats in an hour; ſo are the hours of the face of the clock (viz. 12, or 24) to the quotient of the hour-wheel or dial-wheel divided by the *pinion* of report, that is, by the number of turns which the *pinion* of report hath in one turn of the dial-wheel; which, in numbers, is 26928: 20196 :: 12 : 9.

Or rather thus: as the hours of the watch's going are to the numbers of the turns of the fuſee; ſo are the hours of the face, to the quotient of the *pinion* of report. If the hours be 12, then 16 : 12 :: 12 : 9. But if 24, the proportion is 16 : 12 :: 24 : 18.

This rule may ſerve to lay the *pinion* of report on any other wheel, thus: as the beats, in one turn of any wheel, are to the beats in an hour; ſo are the hours of the face, or dial-plate, of the watch, to the quotient of the dial-wheel, divided by the *pinion* of report, fixed on the ſpindle of the aforeſaid wheel. See CLOCK and MOVEMENT.

PINION, *flying*. See FLYING.

PINIROLO, in *Ornithology*, the name of a bird of the fringa kind, ſomewhat approaching to the ſand-piper, but larger; its beak is a little more than a finger's breadth long, and black; it is of a mixed cheſnut-colour, and brown on the back; and its belly and breaſt are perfectly white: it is common in the Italian markets, and very much reſembles the common fringa.

PINK, in *Botany*. For the characters, ſee DIANTHUS.

Of *pinks* there is a great variety now cultivated in the gardens; the principal of which are, the damaſk *pink*, the white ſtock, the phealant's eye, with double and ſingle flowers, varying greatly in their ſize and colour; the Cob's *pink*, Dobſon's *pink*, white Cob *pink*, and Burr's *pink*: the old man's head, and painted lady *pinks*, alſo belong to the carnation.

The common *pinks* are propagated either by ſeeds (which is the way to obtain new varieties, or by parting the layers of them, as is practiſed for carnations; or by planting

flips, which, if carefully managed, will take root very well.

If they are propagated by ſeeds, there ſhould be care taken in the choice of them, and only the ſeeds of the beſt ſorts ſaved, where perſons are curious to have the fineſt flowers. Theſe ſeeds may be ſown in the ſpring, and the plants afterwards treated in the ſame manner as is directed for the CARNATIONS; with this difference only, that as the *pinks* are leſs tender, ſo they may be more hardily treated. Thoſe which are propagated by layers muſt be almoſt managed as the carnation.

The beſt time to plant the flips of *pinks* is about the end of July, when, if there ſhould happen rain, it will be of great ſervice to them; but if the weather be dry, they will require to be conſtantly watered every other day, until they have taken root; theſe ſhould be planted in a ſhady border, and the ground ſhould be dug well, and all the clods broken, and if no rain falls, it ſhould be well ſoaked with water a few hours before the flips are planted; then the flips ſhould be taken from the plants, and all their lower leaves ſtripped off, and planted as ſoon as poſſible after; for if they are ſuffered to lie long after they are taken from the plants, they will wither and ſpoil: theſe need not be planted at a greater diſtance than three inches ſquare, and the ground muſt be cloſed very hard about them; then they muſt be well watered, and this muſt be repeated as often as is found neceſſary, till the cuttings have taken root; after which they will require no other care but to keep them clean from weeds till autumn, when they ſhould be tranſplanted to the borders of the flower-garden, where they are to remain. There are ſome who plant the flips of *pinks* later in the ſeaſon than here directed; but theſe plants are never ſo ſtrong, nor flower ſo well as thoſe which are early planted. Miller.

PINK, *Indian*, a ſpecies of *ipomœa*. See QUAMOCLIT.

PINK, *Indian*, is alſo a ſpecies of *lonicera*. See *Upright* HONEYSUCKLE.

PINK, *Mompeliet*. See ANTHYLLANTHES.

PINK, *ſea*. See THRIFT.

PINK, *brown*, among *Painters*, is the tinging part of ſome vegetable of a yellow or orange-colour, precipitated upon the earth of alum, cuttle-fiſh bone, or ſome ſimilar calcareous ſubſtance. When good, it is a concentrated yellow, which, as a pigment, is tranſparent in oil, gives the effect of a dark colour, and ſerves for deep ſhades. There are many methods of preparing brown *pink*. One of the beſt and moſt common methods is the following: take of the French berries, one pound; of ſuſtic wood in chips, half a pound; and of pearl-aſhes, one pound. Boil them in a tin-boiler, with a gallon and a half of water, for an hour; and then ſtrain off the tincture through flannel, while the fluid is boiling hot. Having prepared in the mean time a ſolution of a pound and a half of alum, put it gradually to the tincture, as long as an ebullition ſhall appear; waſh the ſediment, as in the preparation of LAKES; and when it is brought, by filtering through paper with a linen cloth, to a proper conſiſtence, dry it on boards in ſquare pieces. Or, it may be made without the uſe of ſalts, by boiling two pounds of the berries in a gallon of water for two hours, and ſtraining off the tincture through flannel. In the mean time prepare a pound and a half of cuttle-fiſh bone, by levigating the ſoft inner part with water on a marble; add this to the tincture, and evaporate them in baſon Marie till the matter becomes of a ſtiff conſiſtence; when the whole has been well mixed by grinding, let it be laid on boards to dry.

The goodneſs of *brown pink* muſt be judged of by its tranſparency, and force of colour, when mixed with oil; but its qualities of ſtanding well, and not fattening in oil, in both which reſpects it is commonly defective, can only be aſcertained by trial and experience.

PINK, *Dutch*, is a pigment formed of chalk, coloured with the tinging particles of French berries, or other vegetables. It is principally uſed for coarſer purpoſes in water. It may be made by boiling one pound of French berries, and four ounces of powdered turmeric root in a gallon of water for two hours, and then ſtraining off the tincture through flannel, and boiling it again with an ounce of alum, till it be evaporated to one quart. Prepare in the mean time four pounds of chalk, by waſhing it over, and afterwards drying it; and mix the chalk with the tincture, by grinding them together, and then dry it on boards. It is ſometimes prepared in the ſame manner with ſtarch and white lead. Its goodneſs conſiſts in its being of a full gold-coloured yellow, and very bright.

PINK, *Engliſh*, is only a lighter and coarſer kind of Dutch *pink*; and may be prepared in the ſame manner, the quantity of chalk being increaſed in proportion, as it is intended to be inferior to the Dutch.

PINK, *light*, is of two kinds; the one being the ſame with the Dutch *pink*, only with much leſs colour, ſo that the proportion of the French berries and turmeric muſt be leſſened to one half: the other is the ſame with the brown *pink*, that is, tranſparent in oil, but with leſs colour. It may be prepared by boiling one pound of French berries in a gallon of water, for an hour, and adding to the ſtrained fluid two pounds of pearl-aſhes, diſſolved and purified, by filtering through paper; then precipitate with alum diſſolved in water, by adding the ſolution gradually, till the ebullition ceaſes; and proceed as with *brown* PINK.

PINK, *roſe*, is a LAKE, the earth or baſis of which is principally chalk, and the tinging ſubſtance is extracted from Braſil or Campeachy wood. This pigment, which does not ſtand, is ſeldom employed, except for the coarſe work of houſe-painters, or for paper-hangings, and ſometimes with varnith. It may be prepared by boiling ſix pounds of Braſil wood, or three pounds of Braſil and three of Campeachy wood, in three gallons of water, in which a quarter of a pound of alum has been diſſolved, for an hour. Purify the fluid, by ſtraining through flannel, and put back the wood into the boiler with the ſame quantity of alum, and proceed as before; repeating the operation a third time; mix the three quantities of tincture together, and evaporate them till only two quarts of fluid remain. Prepare eight pounds of chalk, by waſhing it over in water, in which a pound of alum has been diſſolved, and afterwards fuſing the chalk from the fall, formed by the alum, and drying it to the conſiſtence of a ſtiff clay. Grind the chalk and tincture together; and lay the maſs to dry out of the ſun or cold air. The goodneſs of roſe *pink* conſiſts chiefly in the brightneſs of the colour, and fineneſs of its ſubſtance.

PINK, *pompe*, Fr. in *Sea-Language*, is a name given to a ſhip with a very narrow ſtern; whence all veſſels, however ſmall, whoſe ſterns are faſhioned after this manner, are called *pink-ſterned*.

PINNA, or PENNA, a Latin word ſignifying a FEATHER. It is alſo uſed figuratively, in divers arts, to expreſs things which bear ſome reſemblance, in form, to feathers; as the fins of fiſhes, &c. See FIN.

PINNA *auris*, in *Anatomy*. See EAR.

PINNA *naſi* is the ſame as *ala naſi*. See NOSE.

PINNÆ, *aculei* PINNARUM, in *Ichthyology*. Every apophyſis, or eminence on the head or body of a fiſh, which is ſo ſharp at the end as to be capable of pricking, is called an *aculeus*; but the *aculei pinnarum* in particular are thoſe prickly *radii* or bones, which ſerve to ſupport the fins; and being carried out beyond the rim of the membrane, end in ſo many points.

Theſe *aculei* are ſimple cylindric oſſicles; whereas the other oſſicles, which ſuſtain the fins, are leſs rigid, and are bent and not prickly; and theſe are not ſimple, but are compoſed each of two oſſicles cloſely cohering one to another. Many of theſe *radii* are divaricated at their extremity into two, three, or more branches; theſe, when they are carried out beyond the rim of the membrane, are harmleſs, and are ſeen to be compoſed of two oſſicles, as the body of the radius is. The *aculei* of the back and belly of all fiſhes are ſo fat of the ſame nature, that they never ſtand ſingle, as ſome have ſuppoſed them to do in particular inſtances; but they are always connected one to the other at the bottom by a membrane, though that be ever ſo ſmall and low, as in ſome it is ſcarce viſible.

PINNARUM *radii*. See RADII *pinnarum*.

PINNA, in the Linnæan ſyſtem of *Zoology*, is a genus of the *teſtacea vermia*. Its animal is a ſlug; it is bivalve, fragile, and furniſhed with a beard; it gapes at one end, and has a hinge without a tooth. Linnæus enumerates eight ſpecies.

The *pinna marina* is a ſhell-fiſh like the muſcle, held in its place by a number of threads, which proceed from its body, and are fixed to any adjoining ſubſtance, and is one of thoſe fiſh, which, like the muſcle, has a power of ſpinning in the manner of the ſpider and caterpillar. The threads which theſe fiſh ſpin are infinitely finer and ſlenderer than thoſe of the muſcle, notwithſtanding that the fiſh is vaſtly larger; its ſhells being often found two feet long. Theſe threads are indeed ſcarce leſs fine than the ſingle ſilk threads of the ſilk-worm, and like it have in all times been worked into uſe. The fineſt kind of the byſſus of the ancients was wrought out of theſe threads, and at preſent they are manufactured at Palermo, and at many other places, into gloves, ſtockings, and other ſorts of wearing apparel.

It is eaſy to conceive, that threads ſo fine as theſe can be of no great ſtrength; but what is wanting in the force of each, is made up in the number of them; which are ſpun by every fiſh, for this is almoſt infinite. They differ in nothing from the threads of the muſcles beſide their

their fineneſs and their length; which is in theſe much greater, and therefore makes them much the more valuable. They are probably formed in the ſame manner with thoſe of the muſcles; and the *pinna* may be called, by way of diſtinction, the ſilk-worm of the ſea; and the muſcle, the caterpillar. See *Tab. of Shells*, N° 20. Mem. Acad. Par. 1711.

PINNARUM *dilatator proprius*, in *Anatomy*, a name given by Santorini to one of the muſcles of the face, which he has alſo called *myrtiformis noſi*, and which Cowper has called *depreſſor labii ſuperioris, ſeu conſtrictor alæ noſi*, and Albinus the DEPRESSOR *alæ noſi*.

PINNACE, a ſmall veſſel, navigated with ſails and oars, and carrying generally two maſts; chiefly uſed as a ſcout for intelligence, and for landing of men.

One of the boats belonging to a great man of war, ſerving to carry the officers to and from the ſhore, is alſo called the *pinnace*. It reſembles a barge, but never rows more than eight oars, whereas a barge properly never rows leſs than ten. *Pinnaces* are for the accommodation of lieutenants, &c. as barges are for admirals and captains of ſhips of war.

PINNACLE, from *pinna*, or *pinnaculum*, in *Architecture*, the top or roof of a houſe, terminating in a point.

This kind of roof, among the ancients, was appropriated to temples; their ordinary roofs were all flat, or made in the platform-way.

It was from the *pinnacle*, that the form of the pediment took its riſe.

PINNATED *leaf*, among *Botaniſts*. See LEAF.

PINNATIFID *leaf*, among *Botaniſts*. See LEAF.

PINNATUS, in *Heraldry*, a term uſed by the Latin writers on theſe ſubjects, to expreſs that ſort of line in arms which is called by our heralds the EMBATTLED *line*, or *crenelle*. It is alſo called by ſome *linea pinnis aſperata*, and by Sylveſter Petro Sancto *murales pinnulæ*. When this line is only embattled on one ſide, it is properly expreſſed by this word; but when it is embattled on both ſides, as in ſome arms, it is called *bretteſſe* and *contre bretteſſe*.

PINNING, in *Building*, the faſtening of tiles together, with pins of heart of oak; for the covering of a houſe, &c.

PINNIRAPI, in *Antiquity*, an order of GLADIATORS, who being matched with the SAMNITES, uſed to catch at the *pinnæ* which adorned their helmets, and bear them off in triumph, as marks of victory.

PINT, *pinta*, a veſſel or meaſure uſed in eſtimating the quantity of liquids, and even ſometimes of dry things.

Budæus derives the word *pint* from the Greek πωτὸς; others from the German *pint*, a little meaſure of wine; Nicod from the Greek πινω, *to drink*.

The Engliſh *pint* is a wo'old; the one for wine-meaſure, the other for beer and ale-meaſure.

The wine *pint* is ſaid to contain a full pound, avoirdupois, of common running water; two *pints* make a quart, two quarts a pottle, two pottles a gallon, &c.

The Paris *pint* is eſtimated at one ſixth of the ancient congius, and contains two pounds of common water, and is therefore nearly equal to an Engliſh wine quart; it is divided into ſeſtiers, which ſome call ſeptiers; the ſeptiers into two demiſeptiers, the demiſeptiers into two poſſons, each poſſon containing 12 cubic inches. Two *pints* make a quart, quarteau, which ſome call a pot: the *pint* of St. Denis is almoſt double that of Paris.

In the Engliſh beer-meaſure, the *pint* is the eighth part of a GALLON; conſequently contains 35¼ cubical inches.

As to the *pint* uſed in Scotland, there are different opinions concerning the number of cubical inches it contains. Dr. Gregory makes them 1697; others, from ſeveral careful menſurations of the ſtandard kept at Edinburgh, make the Scotch *pint* to contain 103,2; and thoſe in common uſe are ſaid to contain berwixt 105 and 106 cubical inches. Another experiment was made with weal, which was found to contain 464 Scotch *pints*, and 18,5 Engliſh ale gallons. Suppoſing this menſuration juſt, the Scotch *pint* will be to the Engliſh ale gallon as 289 to 270; and if the Engliſh ale gallon be ſuppoſed to contain 282 cubical inches, the Scotch *pint* will contain 302,84 ſuch inches.

PINTADO, or AVIS AVIS, in *Natural Hiſtory*, a name given by the ancient Roman authors to the GUINEA-*fowl*.

PINTLE, in *Artillery*, a long iron bolt, fixed upon the middle of the limber bolſter, to go through the hole made in the trail-tranſom of a field-carriage, when it is to be tranſported from one place to another. The hole through which the *pintle* paſſes is wider above than below, in order to leave room for the *pintle* to play in.

PINTLE-*plate* is a flat iron, through which the *pintle* paſſes, and nailed to both ſides of the bolſter, with eight diamond-headed nails.

PINTLE-*waſher*, an iron ring, through which the *pintle* paſſes, placed cloſe to the bolſter for the trail to move upon.

PINTLE, *priſtil*, in *Botany*. See WAKE-*robin*.

PINTLES, in a *Ship*, are hooks by which the rudder hangs to the ſtern-poſt.

PINUS. See PINE-*tree*.

PIONEER, in *War*, a labourer employed in an army, to ſmooth the roads, paſs the artillery along, and to dig lines and trenches, mines, and other works.

Menage derives the word from the Latin *poſitores*, a diminutive of *poſites*. Bochart deduces it from the Peones, a people of Aſia, whoſe principal employment was to dig the earth in mines, &c.

Moſt of the foreign regiments of artillery have half a company of *pioneers* well inſtructed in their buſineſs. Our regiments of infantry and cavalry have three or four *pioneers* each, provided with aprons, hatchets, ſaws, ſpades, and pick-axes. They have alſo a cap with a leathern crown, and a black bear-ſkin front, on which is the king's creſt in white, on a red ground, and the number of the regiment on the back part of the cap.

PIONY, *pæonia*, in *Botany*, a genus of the *polyandria digynia* claſs. Its characters are theſe: the flower has a permanent empalement, compoſed of five concave, reflexed leaves; the flower has five large, roundiſh, concave petals, which ſpread open, and a great number of ſhort hairy ſtamina, with two, three, or four, oval, erect hairy germina in the centre, having no ſtyles; the germina afterward become ſo many oval, oblong, reflexed, hairy capſules, having each one cell opening longitudinally, containing ſeveral oval, ſhining-coloured ſeeds, fixed to the furrows. Linnæus reckons two, and Miller ſix ſpecies.

The ſeveral ſorts of this plant, with double flowers, are all very hardy, and will grow in almoſt any ſoil and ſituation; they are propagated by parting the roots, which multiply very faſt. They ſhould be planted in Auguſt, or the beginning of September, and will then flower the ſucceeding ſummer. The off-ſets ſhould not be too ſmall, and ſhould all have a faſt bud or eye. The ſingle kinds may alſo be propagated by ſowing their ſeeds in Auguſt in a light earth, and managing them in the method of all other ſeedling plants. There may probably be ſome good varieties of the flowers produced this way. The ſingle Portugal *piony* is of ſo ſweet a ſmell as to deſerve a place in any garden, though but a ſingle flower. Miller.

The roots, flowers, and ſeeds, of the male and female *piony*, are looked upon as lightly anodyne and corroborant; to the latter of which virtues they appear to have ſome claim. They have been principally recommended in ſpaſmodic and epileptic complaints; in which Dr. Lewis apprehends their effects are not very conſiderable.

PIP, or PEP, *pepia*, a diſeaſe among poultry, conſiſting of a white thin ſkin, or film, that grows under the tip of the tongue, and hinders their feeding.

It uſually ariſes from want of water, or from the drinking puddle-water, or eating filthy meat. It is cured by pulling off the film with the fingers, and rubbing the tongue with ſalt. Hawks are particularly liable to this diſeaſe, eſpecially from feeding on ſtinking fleſh.

PIPE, in *Building*, &c. a canal or conduit for the conveyance of water, and other liquids.

Pipes for water, water-engines, &c. are uſually of lead, iron, earth, or wood. The latter are commonly either oak or alder.

Thoſe of iron are caſt in the forges; their uſual length is about two feet and a half; ſeveral of theſe are commonly faſtened together, by means of four ſcrews at each end, with leather, or old hat, between them, to ſtop the water.

Thoſe of earth are made by the potters. Theſe are fitted into one another, one end being always made wider than the other.

To join them the cloſer, and prevent their leaking, they are covered with pitch and tow. Their length is uſually about the ſame with that of the iron *pipes*.

The wooden *pipes* are bored with large iron augres of different ſizes, ſucceeding one another from leſs to larger; the firſt pointed, the reſt formed ſpoon-wiſe, increaſing, in diameter, from one inch to ſix. See BORING *of wooden-pipes*. They are fitted into the extremities of each other, and are ſold by the foot.

Leaden *pipes* are of two kinds; the one ſoldered, the other not ſoldered: for the conſtruction of each kind whereof, ſee PLUMBERY.

For the PIPES *of organs*, See ORGAN.

*Bag-*PIPE. See BAG-PIPE.

PIPE is alſo a popular machine uſed in the ſmoaking of tobacco; conſiſting of a long ſlender tube, made of earth or clay; having, at one end, a little bole, or furnace, called the *bowl*, for the reception of the tobacco; the

fumes whereof are drawn by the mouth through the other end.

Pipes are made of various fashions, long, short, plain, worked, white, varnished, unvarnished, and of various colours, &c. The Turks use *pipes* three or four feet long, made of rushes, or of wood bored; at the end whereof they fix a kind of nut, of baked earth, which serves as a bowl, and which they take off when smoking. These they carry with them when they travel; they have made to screw three joints, to put into a bag; they cover the tube sometimes with cloth, and dip it in water to make it smoke cool.

The instrument used by the Persians for smoking, and called *nargui*, is so constructed, that the smoke of the tobacco passes through water before it comes into the mouth.

PIPE-*office*. See ACTS and TOBACCO-*pipe fish*.

PIPE, *tone*. See HORN-*fish*.

PIPE-*fish*, in *Botany*. See PHILADELPHUS and BILAC.

PIPE-*wort*, *tobacco*. See CASSIA.

PIPER, in *Mining*, is where the ore runs for warm endeavs in a body, and doth not sink downwards, or lie a vein.

PIPE-*ore*, an invention of the late ingenious Mr. Sutton, to clear flues of foul air. This he does by a *pipe*, the branches of which are laid in the hold, and the extremity of which is fixed into the altarside of the furnace. Mr. Watson has shewn how these *pipes* may be laid, so as to be no way inconvenient, and relates the success of a trial of them, made on a sink. See Phil. Trans. N° 462, p. 42.

We have now three different contrivances published for cleaning flues, and other close places, of foul air.

One by Dr. Desaguliers, which will change the air in the chamber of sick people, in a little time; either by drawing out the foul air, or driving in fresh; or doing both successfully, without opening doors or windows. See Phil. Trans. N° 437.

The other by Mr. Button before mentioned; and the third by means of Dr. Hales's ventilators, which seems to be the most expeditious and simple method. See VENTILATOR.

PIPE, *pipa*, in *Law*, is a roll in the exchequer, called also the *great roll*.

PIPE-*office* is an office wherein a person called the *clerk of the pipe* makes out leases of crown lands, by warrant from the lord-treasurer, or commissioners of the treasury, or chancellor of the exchequer.

Clerk of the pipe makes up all accounts of sheriffs, &c. and gives the accountants their quietus est. To this office are brought all accompts which pass the remembrancer's office, and remain there; that if any fleated debt be due from any person, the same may be drawn down into the great roll of the *pipe*, from the form of which he receives his name; upon which the comptroller issues out a writ, called the *summons of the pipe*, for recovery thereof. And if there be no goods or chattels, the clerk then draws down the debts in the lord-treasurer's remembrancer, to write threats against their lands.

All tallies, which touch the payment of any sum contained in such accompts, are examined, and allowed, by the chief *secretary of the pipe*.

Besides the chief clerk, and his deputy, in this office are a first and second secondary, six attorneys, or sworn clerks, and a comptroller, deputy and clerk, board-clerk, clerks, and tub-bearer.

PIPER, in *Botany*. See PEPPER.

PIPER *Africum*, in *Botany*, a name given by some authors to the *cubebs-berry-tree*, or *cassia caryophyllata*.

PIPER, in *Ichthyology*, the English name of a Species of TRIGLA, with a tubid snout, and tubulose nostrils. It is called by the generality of authors LYRA. See TRIGLA.

PIPER *Jamaicæ*, the *pepper-tree* of Jamaica. See PIMENTO.

PIPER *Nigrum*, *Negro pepper*. The plant called at present by this name is the CAPSICUM; or *Guinea pepper*, a remarkable herb, bearing large pods as red as coral, of which the Cayan button is made in America. But this is not the plant that was anciently known by this name. Avicenna and Serapion both mention a plant, which they call *fulfel albeth*, the English of which is, *the pepper of the white pepper*. But this was properly what has been since called the *Ethiopian pepper*; a sort of but seeds approaching to the nature of the common *pepper*, and containing several together in pods.

It is not easy, from the account we have left, to say what it is; but they have left description enough of it for us to say what it is not, and to find that they have all been mistaken, who have supposed it to be either the root tabi, or the sarmæ of the Arabians, which last was as large as a pear.

PIPER, *pied*, in *Ornithology*. See AREDARIA and SANDpiper.

PIPER *sylvestris*, in *Botany*, the clove-berry-tree, or *cubeba caryophyllata*, a tree whose bark is used in medicine.

PIPERARIUM, an old name of a plant found in Apulcius, and said to have had name from its use to the table; which was to offend us to the best, that if a piece of it were flung up in their hive, it would drive them all out.

This is a very strange account; and as we meet with nothing to countenance it in any other author, *there is reason to suspect it to be an error*; and there seems this occasion for it. The *acorus* root is said by Dioscorides to be the root of a plant allied to the papyrus, or paper-reed of the river Nile; and is thence called by that author *papyrosacus*. Avicenna and Serapion copy this, and frame the acorus plant to the *papyrus*; but in all the copies of the Greek author, it is often found written *piperosacus*. This word *piperosacus* may have been formed by Apuleius into *piperarium*, by way of an endowment, and all the rest might be occasioned by this.

PIPERITIS, in *Botany*, a name given by some authors to the *mint-plant*, or *mint*. See MENTHA *aquat.*

PIPERIVORA *avis*, in *Ornithology*, a name given by some authors to the TOUCAN, or Brasilian magpie, from its feeding on pepper.

PIPING, in *Sea-Language*. See CALL.

PIPPERIDGE-*tree*, in *Botany*. See BARBERRY-*tree*.

PIPRA, in *Ornithology*, a name given by Aristotle, and other ancient writers, to the *picus varius major*, the great spotted wood-pecker, or wet-wall.

PIPRA, in the Linnæan System of *Ornithology*, a genus of the PASSERES. Its characters are, that the bill is shorter than the head, three-cornered at the base, entire, and incurvated at the apex; the feet are formed for walking. Linnæus enumerates thirteen species.

PIQUE, in *Natural History*, a name given by the Spaniards to an insect of the tick of a flea, called by the Indians TUNG. It is common in the East and West Indies, and eats its way into the flesh under the nails, &c.

PIQUET. See PACKET.

PIQUETTE, among the *Florists*, a term used for a certain sort of carnations, which have always a white ground, and are spotted, or, as they call it, pounced with scarlet, red, purple, or other colours.

PIQUITINGA, in *Ichthyology*, the name of a small American river-fish. It seldom exceeds two inches in length; its mouth appears very small, but it can so plentifully open it to a great width; its eyes are very large and bright, with a silvery iris; it has six fins besides the tail, which is forked; its head is of a silvery white; its back olive colour, and its belly and sides are covered with silvery scales; the fins are all white, and the finlets are black, and very bright and shining. Margrave.

PIRA, in *Ichthyology*, a name by which Margrave and some other authors have called a quite horned fish of the West Indies, called by Clusius and others, the MONOCERAT *pisces*, or unicorn fish.

PIRA-*acanga*, in *Ichthyology*, the name of a Brasilian fish, resembling the perch in face and shape. It is of a small size, seldom exceeding four or five inches in length; its mouth is small; its tail is forked; and it has on the back only one long fin, which is supported by rigid and prickly spines; this it can depress at pleasure, and lurk within a cavity made for it in the back; its scales are of a silvery white. It is a wholesome and well-tasted fish. Margrave.

PIRA-*cucha*, in *Ichthyology*, a name used by some authors for the MILVUS, or kite-fish.

PIRA-*jubda*, in *Ichthyology*, the name of an American fish of the multifarious kind, much esteemed for the delicacy of its flesh. It grows to about twelve inches in length; its nose is pointed, and its mouth large, but without teeth; the upper jaw is longer than the other, and hangs over it in form of a cartilaginous prominence; its eyes are very large, and its tail forked; under each of the gill-fins it has a beard made of six white filaments, and is covered all over with silvery scales. Margrave.

PIRA-*jurumbaia*, in *Ichthyology*, the name of a Brasilian fish, called by many the *lupus minor*. It lives in the muddy bottom of the American seas, and is a long-bodied not flatted fish; it grows to a sufficient size, being sometimes caught of nine, and sometimes even of ten or eleven feet long, and two feet and a half thick; it has one long fin on the back, the anterior part of which is thin and prickled, and has a cavity on the back, into which the creature can depress the fin at pleasure; its tail is not forked; its scales are all of a silvery colour and brightness. It is a very well-tasted fish. Margrave.

PIRA-*sapanga*, in *Ichthyology*, the name of a Brasilian fish of the cardus or wrasse kind, and called by some the *gut-fish*. Its usual length is four or five inches; its mouth is considerably large, and furnished with very small and sharp teeth; its head is small, but its eyes large and pro-

minent; the pupil of a fine turquoise colour, and the iris yellow and red in various shades; the coverings of the gills end in a triangular figure, and are terminated by a short spine or prickle; its scales are very small, and so evenly arranged, and closely laid on the flesh, that it is very smooth to the touch; its tail is not forked, but rounded at the end; its whole body, head, tail, and fins, are of a pale yellow, variegated all over with very beautiful blood-coloured spots; these are round, and of the bigness of hemp-seed on the back and sides, and something larger on the belly; the fins are also spotted in the same manner, and are all marked with an edge of red. It is caught among the rocks, and about the shores, and is a very well tasted fish. Marggrave.

PIRANHA, in *Ichthyology*, a name given to the American fish more commonly known by the name PIRAYA.

PIRAQUIBA, or IEIRAQUEIRA, in *Ichthyology*, a name originally Brasilian, by which some authors express the REMORA, or sucking-fish.

PIRATE, *pyrata, piratus, raver*; a person, or vessel, that robs on the high seas, or makes descents on the coasts, &c. without the permission, or authority, of any prince or state.

The colours usually displayed by *pirates* are said to be a black field, with a death's head, a battle-axe, and an hour-glass.

By the ancient common law, *piracy*, if committed by a subject, was held to be a species of treason, and by an alien to be a felony only; but now, since the statute of treasons, 25 Edw. III. cap. 2. it is held to be only felony in a subject. Formerly it was only cognizable by the admiralty courts, which proceed by the rules of the civil law; but the statute 28 Hen VIII. cap. 15. established a new jurisdiction for this purpose, which proceeds according to the course of the common law. The offence of *piracy*, by common law, consists in committing those acts of robbery and depredation upon the high seas, which, if committed upon land, would have amounted to felony. But, by statute, some other offences are made *piracy* also; as by 11 & 12 W. III. cap. 7. if any natural born subject commits any act of hostility upon the high seas, against others of his majesty's subjects, under colour of a commission from any foreign power, this, which would be only an act of war in an alien, shall be construed *piracy* in a subject. And further, any commander, or other sea-faring person, betraying his trust, and running away with any ship, boat, ordnance, ammunition, or goods, or yielding them up voluntarily to a *pirate*, or conspiring to do these acts; or any person confining the commander of a vessel, to hinder him from fighting in defence of his ship, or to cause a revolt on board, shall, for each of these offences, be adjudged a *pirate*, felon, and robber, and shall suffer death, whether he be a principal or accessory. By 8 Geo I. cap. 24. the trading with known *pirates*, or furnishing them with stores or ammunition, or sitting out any vessel for that purpose, or in any wise consulting, combining, confederating, or corresponding with them; or the forcibly boarding any merchant vessel, though without seizing or carrying her off, and destroying or throwing any of the goods overboard, shall be deemed *piracy*; and all accessories to *piracy* are declared to be principal *pirates* and felons, without benefit of clergy. Commanders or seamen wounded, and the widows of such as are slain, in any *piratical* engagement, shall be entitled to a bounty, to be divided among them, not exceeding one fiftieth part of the value of the cargo on board; and such wounded seamen shall be entitled to the pension of Greenwich hospital. And if the commander shall behave cowardly, by not defending the ship, if she carries guns or arms, or shall discharge the mariners for fighting, so that the ship falls into the hands of *pirates*, such commander shall forfeit all his wages, and suffer six months imprisonment.

In different parts *pirates* are differently denominated; as in the West-Indies, *buccaneers, free-booters*, &c. In the Mediterranean, *corsairs*, &c.

Alexander, reproaching a *pirate* with his condition, was answered, "If I am a *pirate*, it is because I have only "a single vessel; had I a fleet, I should be a mighty "conqueror."

PIRATE was also anciently used for the person to whose care the mole, or port, of a haven, which in Latin was called *portus*, was entrusted.

PIRATE was sometimes too, according to Spelman, used for a sea-captain, or soldier. After, in the life of King Alfred, tells us, *infelix navim longam fabricavit, longitudine pariter in illius vitæ navigia cæteris duplo excedentem.*

PIRATIA-*piso*, in *Ichthyology*, the name of an American sea-fish, which grows to a very large size, and, while young, is eaten and accounted a delicacy; but, when full grown, is too coarse, rank, and strong; it has six fins besides the tail, which is made of a very large fin, of a somewhat square figure, and is not at all forked; it is all over of a dusky orange colour, but more obscurely so on the back than elsewhere; and its sides are variegated with grey spots, so disposed as to represent a sort of net-work. Piso.

PIRATIAPIA, in *Ichthyology*, the name of a Brasilian fish, approaching to the nature of the turbot or wrasse. Its body is oblong, not flatted, and very thick; it is a large fish, and sometimes grows even to fifty pounds weight. It is a very delicate and valuable fish. Marggrave.

PIRAUMBU, in *Ichthyology*, the name of a Brasilian fish, somewhat approaching to the nature of the turbot, and called by the Portuguese *thargarreo*. It is of the figure of the carp, and its usual length is six or seven inches, and its breadth in the broadest part about three inches, but gradually diminishing to the tail. It is caught among the rocks, and near shores, and is a well-tasted fish. Marggrave.

PIRAYA, in *Ichthyology*, the name of a fish caught in the American rivers. There are two kinds of it; the one growing to a foot long, and very broad in proportion; this loves the muddy bottoms of rivers; the other is much of the same size, but has two fins on its back, whereas the other has but one; this loves the sandy bottoms of rivers. There is also a smaller species of this; all three are eatable fish.

PIRIT, in *Natural History*, a name given by the people of the Philippine islands to a peculiar species of sparrow, which is very common with them. It is much smaller than our common sparrow, and feeds only on the seeds of the canary-grass, which is very commonly wild there.

PIROUETTE, or PYROUET, in the *Manege*, a turn or circumvolution which a horse makes, without changing his ground, his haunches remaining firm in the centre, and his shoulders forming and describing the circle. In this action the inner hind-leg must not be lifted from the ground, but turned round in the same place, like a pivot, while the other three legs, and the body of the horse, turn and wheel round it at the same time.

The word is French, and literally signifies a whirligig.

Pirouettes are either of *one tread* or *fish*, or of *two*. The first is an entire short turn which the horse makes upon one tread, and, almost, in one time; in such manner as that his head comes to the place where his tail was, without putting out his haunches. In the *pirouette* of *two treads* or *fishes*, he takes a small compass of ground, almost his length, and marks both with the fore-part and the hind.

PISCARY, *piscaria*, in our *Ancient Statutes*, the liberty of fishing in another man's waters.

This differs from a free fishery, which is an exclusive right: in this last a man has a property in the fish before they are caught; in a common of *piscary*, not till afterwards.

PISCES, in *Astronomy*, the twelfth sign, or constellation, of the zodiac.

The stars in *Pisces*, in Ptolemy's Catalogue, are 38; in Tycho's 36; in Hevelius 30; in the Britannic Catalogue 113; the longitudes, latitudes, magnitudes, &c. whereof are as follow.

PISCIDIA, in *Botany*, a genus of the *decandria dimynia* class. Its characters are, that it has an acute stigma, and a winged pod. There are two species.

PISCINA, in *Antiquity*, a large bason, in an open public place, or square, where the Roman youth learnt to swim; and which was surrounded with a high wall, to prevent the exiling of fish into it.

The word is formed from the Latin *piscis*, *fish*; because men here imitated fishes in swimming, and because fishes were actually kept in some of these places.

PISCINA was also used for the square bason in the middle of a bath.

PISCINA *probatica* was a pool or reservoir of water, near the court of Solomon's temple; so called from the Greek *προβατον*, *sheep*; because here they washed the cattle which were destined for sacrifice.

By this *piscina* it was that our Saviour wrought the miraculous cure of the paralytic. Davila observes, there are still remaining five arches of the portico, and part of the bason, of this *piscina*.

PISCINA, or *lavatory*, among the Turks, is a large bason placed in the middle of the court of a mosque, or under the porticus that encompass it.

Its form is usually a long square. It is built of stone or marble, furnished with a great number of cocks, where in the mussulmans wash themselves before they offer their prayers; as being persuaded, that ablution effaces sin.

PISCIS, in *Zoology*. See FISH.

PISCIS *australis*, in *Astronomy*. See AUSTRALIS.

PISCIS *fossilis*, in *Ichthyology*, a name given by Jonston to a kind of the cobitis, found buried in the land, and dug out by the people of many parts of Germany for food. It is called by many authors the *mustela fossilis*, and by some the *perca*. It is properly a species of cobitis, and is called by Artedi the *cobitis cirris*, with five longitudinal black lines on each side of the body.

PISCIS *fossilis Petri*, in *Ichthyology*, a name given by Jonston and some other authors to the *faber* or *John* DORE. It is properly a species of ZEUS.

PISCIS *volans*, the *flying fish*, in *Astronomy*, is a small constellation of the southern hemisphere, unknown to the ancients, and invisible to us in these northern regions. It contains eight stars, whose longitudes and latitudes, &c. are as follow:

Names and situations of the stars.	Signs.	Longitud.	Latitude.	Magnitude.
		° ′ ″	° ′ ″	
In the head	♋	16 36 14	72 22 35 S	5

Lower		15 38 28	72 27 26 S	5
In the right wing, upper	♍	3 31 11	76 45 0 S	6
Lower		11 51 58	79 21 46 S	5
Informis, between Chamæleon and the *Flying fish*		14 11 45	67 52 34 S	5

PISCIVOROUS *animals*, are such as feed on fish. See BIRD.

PISELAMIN *plum*, in *Botany*. *See Indian Date* PLUM.

PISMIRE, or ANT.

PISONIA, in *Botany*, the name given by Plumier, in honour of *Piso*, to a genus of plants, called by Vaillant *Guettarda*. See PINGRICO.

PISSASPHALTUM, or PISSASPHALTUS, *mineralogy*, compounded of *pissa*, *pitch*, and *asphaltum*, *bitumen*, in *Natural History*, denotes a native, solid bitumen, found in the Cevennes mountains of Apollonia; of an intermediate nature between pitch and asphaltum. Its characters are these: *The pissasphaltum* is a solid mineral bodies, of a form so that thick consistence, dusky, and opaque; of a strong smell, and readily inflammable, but leaving a reddish mass after burning.

There are three known species of this genus. 1. A thin and blackish kind, called *oleum petræ*. See OIL of the earth, and PETROL.

2. A thicker black one, called *pissasphaltum Indicum*, or BARBADOES *tar*. And, 3. A black and viscous one, called simply *pissasphaltum* in the shops.

Pissasphaltum is as tough and viscous as bird-lime, and of the same consistence when old. It very much resembles the common black pitch, when softened a little by heat; and has been generally thought to have something of the smell of that substance; but this seems to have arisen from its being too frequently adulterated by mixing pitch with it, and the true genuine substance has no other smell than the rank one of all the bitumens, which somewhat resembles that of oil of amber. It is produced in several parts of the world, and there are large quantities of it in Germany, in Persia, and in France. It yields a liniment oil by distillation, which very much resembles the native petroleum; and is too often sold with it under the name, being annually imported in large quantities from those parts of Germany where it is manufactured, and having itself no particular name in the shops of our druggists.

Pissasphaltum was much recommended by the ancients for external use, as an emollient, maturant, and digestive: with this intention it was used in cataplasms, for ripening all sorts of tumours, and against the sciatica and other pains of the limbs. They also had recourse to it for strengthening the limbs, after the reduction of dislocations. It is little used at present, the petroleum being thought very proper to supply its place.

PISSAVHELETUM is also a name given to a fictitious substance, compounded of pitch and asphaltus, or the true bitumen Judaicum.

The coarseness of this, the black colour, and the fetidness of the smell, distinguish it from the true asphaltum.

PISSAVHELTUM is also used, by some writers, to denote the sweet pitch, or simple asphaltus.

PISSELÆUM, *wax-cake*, *clean* PICTUM, or oil of pitch, a medicament compounded of oil and pitch.

PISSELEUM *Indicum*, among *Modern Writers*, denotes a bituminous substance brought from the West Indies, popularly called BARBADOES-*tar*.

It is a heavy, thick, and dusky-looking mineral fluid, of the colour and consistence of common treacle, and of a very opake hue: it is of a disagreeable smell, faintly approaching to that of oil of amber, and is very inflammable. It is found trickling down the sides of the mountains at the back of several of our plantations in America, and is in great esteem there for coughs and disorders of the lungs. We meet with very little in England that is genuine, several different sophistications of it being in common use, even upon the spot. See PETROL. It has a strong smell not unlike the common tar, and is not very pleasant to sight or taste. It is accounted a good balsamic, and where the stomach can dispense with it, will do great service in many disorders of the breast, which has also been experienced of common tar.

PISSEROS, the name of an ointment greatly recommended by Hippocrates in many cases, as in burns, fresh wounds, &c. It was made of oil of roses, beeswax, and pitch, proportioned so as to give the whole a soft consistence. It was of the nature of our modern black basilicon, and found a good ointment in many cases.

PISSINUM. Pliny says it was customary for the ancients to hold fleeces of wool over the steam of boiling tar, and squeeze the moisture from them, which watery substance was called *pissinum*.

But will have this to be the same with the *pisselæum* of the ancients: but Hardouin, in his notes on Pliny, thinks the *pissinum* to have been produced from the cones of cedars. What use they made of these liquors anciently is not known; but it may be presumed they were used in medicine, though at present it does not appear they are used at all.

PISSITES, a name given by the ancients to a wine impregnated with the virtues of liquid pitch or tar. To prepare it, the tar was ordered to be washed in sea-water or brine, and afterwards in fresh water many times; and after a tedious preparation of this kind, two ounces of it were ordered to be put to eight gallons of must, which is to be suffered to work together, and then the clear liquor to be bottled off.

This was accounted a warm wine, very assistant to concoction, and of an abstersive faculty, and a good pectoral: on these accounts it was given in disorders of the breast, and in obstructions of the liver, spleen, and uterus, if not attended with a fever; and was a common medicine in coughs and asthmas of all kinds.

PISSOCEROS, a name given by the old naturalists to a fubstance found very frequently in the lines of trees, and consisting of a mixture of propolis and wax. The ancients were well acquainted with the use of this substance, which was called the stopping up the cracks and chinks in the hives: they mention, indeed, three sorts of matter used by the bees for this purpose; the mercy, the *pissoceros*, and the propolis; but later authors call them all by the general term propolis, the *pissoceros* and mercy being only the same substance, mixed with wax in different proportions. This PROPOLIS is a resinous substance, of a soft and viscous consistence, collected from the buds of the poplar and other trees.

PISSOSUS, a word used by the old writers on medicine for the depraved appetite of young women about the full eruption of the menses, and of some women with child.

PISTACHIA *bastard*, in *Botany*, a name improperly given by some authors to the tribulant American BLADDER-NUT.

PISTACHIA, or PISTACH-*nut*, a fruit brought from several parts of Asia, chiefly from Aleppo and Persia. When swept in all its coats, it is of the size of a green almond; but when stripped of all but its shell, it resembles a small nut. The kernel is red without, and green within; its taste is very agreeable.

The word is formed from the Latin *Pistacium*, of the Greek *pistakion*, which, according to Menage, the city Pistacium took its name.

The tree that produces it is a kind of turpentine-tree. See MASTICH-*tree*.

The nuts are to be chosen new, heavy, and full; as to those that are broken, such as have kept their colours best are to be preferred; for nothing depends upon the fize.

Pistachios are aperitive, and propre to give vigour; and are used in confections, &c. in phthisical and nephritical cases. They also cure several agues, and are comfited, made into conserves, &c. There is likewise a kind of false *pistachio*, brought from the Caribbee islands, which some confound with the last-named, though very different, both with regard to the plants that produce them, and their quality. The former *pistachio* plant does not rise above a foot high, nor does the fruit grow on the branches, but is found at root. The pod sometimes only contains a single nut, which resembles an olive; but usually several; and in that case they are irregular. The substance is white, compact, and heavy.

This fruit is rarely eat raw, because of the ill effects it produces; it is usually roasted or comfited; it is used in ragouts, and to make tarts, &c.

PISTACHIA-*tree, shrub Pistachio*, a species of the *Rhamnus*. See *Plate* HALF.

PISTANA, in *Botany*, a name by which some authors have called the *sagittaria aquatica*, or water arrow-head.

PISTATIO, among *Pharmaceutic Writers*, a word used to express that preparation of simples which consists in covering them with, or including them in, a pulse, and feeding them in a baker's oven till tender throughout. Squills are sometimes prepared thus.

PISTEREEN, a Spanish coin, worth about a shilling.

PISTE, in the *Manege*, the track or trail, which a horse makes upon the ground he goes over.

The word is French, and literally signifies a *track*.

The *piste* of a horse may be either *high* or *low*.

If the rider make him go but an ordinary gallop, in a circle, or rather circles, he will make but a *large piste*: if he either make him gallop with his haunches in, or go terra à terra, he will make two *pistes*, one with the forepart, another with the hind. And the same if the rider make him manage, by go sideways, either in a strait line, or upon a circle.

PISTIA, *water-cabbage*, or *lettuce*, in *Botany*, the name given by Linnæus to a genus of plants of the gynandria-polyandria class and order, called *pistia* by Plumier, and in the Hortus Malabaricus. The characters of these are these: there is no cup: the flower consists of one petal, which is cucullated and rubinated, and the [illegible] linæ, and long lip, bent and folded [illegible] are no stamina, but six double anthers [illegible]

under the ſtigma; the germen of the piſtil is of an oval oblong figure; the ſtyle is ſhorter than the flower; the ſtigma is peltated, and obtuſely divided into ſix ſegments; the fruit is a capſule of an oval figure attenuated at the baſe, and contains one cell; the ſeeds are truncated. This genus ſeems nearly allied to the birth-worts. There is one ſpecies.

PISTIL, among *Botaniſts*, the female organ of generation in flowers. It is compoſed of three parts, the germen, the ſtyle, and the ſtigma: the germen ſupplies the place of the uterus in plants; its ſhape is various, but it is always ſituated at the bottom of the *piſtil*, and contains the embryo ſeeds: the ſtyle is a part of various figures alſo, but is always placed on the germen; in ſome it is extremely ſhort, in others it ſeems entirely wanting: the ſtigma is alſo of various figures; its place, however, is certain, as it always ſtands on the top of the ſtyle, and if there is no ſtyle, on the top of the germen.

The *piſtil* is an eſſential part of a flower; and the principal female organ of generation; it being in this that the ſeeds or young plants are formed.

It ariſes from the pedicle of the flower, or the centre of the calyx; and at length becomes the young fruit, which is ſometimes hid in the calyx, and ſometimes ſtands quite out.

The figure of the *piſtil* is very different in different flowers: ſometimes it is a little ſtalk, which enlarges at the two ends like a peſtle; ſometimes it is a mere ſtamen, or threat; ſometimes it is round, ſometimes ſquare, triangular, oval, &c.

Almoſt all *piſtils* are furniſhed at top, either with fine hairs, which make a kind of velvetting; or with little filaments diſpoſed in plumes; or elſe they are beſet with little veſicles full of glutinous juice.

Some flowers have ſeveral *piſtils*; or rather the *piſtils* terminate in ſeveral branches or horns, which have their riſe from as many young fruits, or as many different capſulæ, containing ſeeds.

All theſe *piſtils*, whatever form they be in, have certain apertures at their tops, or certain clefts continued the whole length, to the baſe or embryo of the fruit. This is very viſible in the lily, daffodil, and melon, either by cleaving the *piſtils* lengthwiſe, or cutting them tranſverſly. If, after cutting the *piſtil* of the lily, you immerge one extremity in water, and ſuck through the other end, the water will riſe through it as through a pipe.

By opening the *piſtils* in their different ſtates of growth, it appears evidently, that theſe form the young fruits, and contain within them the embryos of the ſeeds; whether thoſe ſeeds be diffuſed through the whole length of the *piſtil*, or whether they be all incloſed in its baſe; and that they are always open at top, and perforated either more or leſs ſenſibly, to the bottom; though this cavity is frequently effaced as the young fruit grows; and ſometimes a part of the *piſtil*, which Malpighi calls the *ſtyle*, or bodkin, dries and falls off.

The *piſtil*, we have obſerved, is the female organ of generation; its baſe does the office of the uterus, or womb, in women; and its length that of the vagina.

It is encompaſſed with the ſtamina, the apices whereof are full of a fine duſt called *farina fœcundans*; which burſting its veſicuhæ, or apices, when mature, is ſhed on the upper part of the *piſtil*, and thence is conveyed by the cavity thereof to the baſe or uterus; where being ſeſ with a fine juice, ſecreted by the petals, it grows, expands, and thus forms the embryo of a new plant, &c. For a more diſtinct account of the office of the *piſtil* in the generation of plants, ſee PLANT.

PISTIS, in the *Materia Medica of the Ancients*, a name given to the gum bdellium, particularly to that kind of it which was brought from Arabia, and was of a fine yelloviſh white, and in ſmall round drops, or lumps of a roundiſh ſhape, and firm conſiſtence.

PISTOL, a little fire-arm, borne at the ſaddle-bow, at the girdle, or in the pocket.

The *piſtol* is ſaid to have taken its name from *Piſtoya*, a city in Italy; where, as Fauchet tells us, it was firſt made. Borel derives the word from *fiſtula*, *pipe*; the barrel of this piece bearing ſome reſemblance to a flute.

PISTOLE, *doubloon*, in *Commerce*, a gold coin ſtruck in Spain, and ſeveral parts of Italy, Switzerland, &c.

It has its augmentations, and diminutions; which are *quadruple-piſtoles*, *double piſtoles*, and *half piſtoles*.

The *piſtole* is about the ſame weight, fineneſs, and value, with the French louis d'or; viz. it is equal to about ſixteen ſhillings and ſix pence ſterling.

In Spain the *piſtole* is accounted equal to four pieces of eight, or thirty-two rials, or a thouſand and eighty-eight maravadis, or a thouſand three hundred and ſixty maravadis of billon; the old money current at Seville and Cadiz, in Andaluſia, &c. being 25 per cent. better than the money they now reckon by at Madrid, Bilboa, &c. which augmentation was made by Charles II. in 1668, to prevent the exportation of money out of the kingdom.

Moſt of the exchanges in Italy are made on the foot of the *piſtole*.

PISTOLOCHIA, in *Botany*, a name uſed by ſome authors for the plant of which the Virginian ſnake-root of the ſhops is the root.

PISTON, a part or member in ſeveral machines, particularly pumps, air-pumps, ſyringes, &c. called alſo the *embolus*, and popularly the *ſucker*.

The *piſton* of a pump is a ſhort cylinder of metal, fixed exactly to the cavity of the barrel, or body; and which, being worked up and down alternately therein, raiſes the water; and when raiſed, preſſes it again, ſo as to make it force up a valve where with it is furniſhed, and to eſcape through the noſe of the PUMP.

There are two ſorts of *piſtons* uſed in pumps; the one with a valve, which is called a *ſucker*; and the other without a valve, which is called a FORCER.

The *piſtons* of air-pumps, ſyringes, &c. ſee deſcribed under AIR-PUMP and SYRINGE.

PISUM, in *Botany*. See PEA.

PIT *and gallows*, in our *Ancient Cuſtoms*. See FURCA and FOSSA.

PIT, *brine*, the name given by the people of Worceſterſhire and Cheſhire, to the wells or *pits* affording the ſalt water, out of which they extract the ſalt.

Theſe waters, though they all contain ſalt, yet have other things alſo in them, and theſe not in ſmall quantity. They all contain a very large proportion of ſtony matter; this is common to the whole ſet, but particular ſubſtances beſide this are found in the particular *pits*. At Northwich, in Cheſhire, there are four *pits*, the water of all which ſtinks very ſtrongly of ſulphur, and contains ſo much vitriol, that it will turn black like ink, with a decoction of galls; yet this is boiled into a very fine and pure kind of ſalt, common at our tables under the name of baſket ſalt, and having no ſuch properties.

There is a vaſt quantity of ſtony matter precipitated from theſe pans of *brine* in the boiling them to ſalt; this is partly ſaved in ſmall pans ſet at the ſide of the boiler, and partly precipitates to the bottom of the pan, where it forms a cruſt like that at the bottom and ſides of our tea-kettles, which the workmen find it neceſſary to remove every week; but there is no vitriol or ſulphur ſeparated. Phil. Tranſ. N° 150.

In the country near where theſe *brine-pits* are, the inſtruments uſed in boring often bring up fine and hard ſalt; ſo that they give proofs of there being rocks of ſalt in many places.

All along the river Weever, on each ſide, the earth affords *brine* wherever it is opened: but all theſe are not fit for boiling, many of the *pits* affording a *brine* too weak to be worked to any advantage. The very ſtrongeſt *pits* ſometimes alſo become at once too weak; this is owing to the irruption of freſh ſprings into them, and ſometimes the river itſelf makes its way into them, and overflows them with ſuch a quantity of freſh water, that they are utterly ſpoiled. The *brine-pits* at Weſton near Stafford afford a *brine* that ſtinks like rotten eggs; this turns inſtantly to ink with galls, and purges and vomits violently, if taken even in a ſmall quantity. This in boiling depoſits a white flaky ſand, or ſtony matter, without ſmell or taſte, and the ſalt is pure and fine.

The *pit* at Droitwich, in Worceſterſhire, affords no ſand in the boiling, nor any the leaſt ſediment of the ſtony matter at the bottom of the pan, and the ſalt is the pureſt of all the others: and by the people of the country it is eſteemed the moſt wholeſome; becauſe of its being without the ſand.

This and the other *pits* hereabout, all have the ſmell of rotten eggs, eſpecially after a little reſt, as on the Monday morning after the Sunday's reſt. If meat be put to pickle in the brine of theſe *pits*, inſtead of being preſerved it will ſtink in twenty-four hours, ſometimes in twelve, yet they yield the beſt ſalt of any inland *pits* in the world.

The ſulphur ſpaws of Yorkſhire, which are very numerous in different parts of the county, all ſtink violently of rotten eggs; but if well drawn and worked, they would prove as inoffenſive as the reſt, and only ſo many weaker or ſtronger brine *pits*; and the ſmell is no other than that of the Cheſhire and Staffordſhire brine, when it has been left ſome time at reſt. It is remarkable, that though the ſtony matter is depoſited in ſuch vaſt plenty by the waters of all our ſalt ſprings, it is not found in any abundance in thoſe places where ſalt is made out of ſea-ſand, as in Lancaſhire and ſome other places; ſo that it is much more than the natural quantity of ſpar contained in water that is thus depoſited; and indeed it appears from trial, that the brine of our ſalt ſprings, in

general, contains more than twenty times the quantity of four that common water does.

This stony matter separates itself from the water before the salt does, and thus it appears in many other waters impregnated with mineral particles. The vitriolic waters all contain ochre and salt, and in all these the ochre separates itself first in the boiling, and then the vitriol; and the stony matter precipitated from common salt springs affords, on an analysis, the salt called *nitrum calcarium*, in considerable abundance. Phil. Transf. N° 156.

PIT, *coal*. See COAL.

PIT, *teeth*. See COCK *pit*.

PIT, *foss*. See SAW.

PIT *of a theatre*, all that space between the amphitheatre or galleries, and the theatre or stage; called by the ancients *orchestra*; and by the French, *parterre*.

This being the most commodious part, it was here the Roman senate was placed. It has its name *pit*, in Latin *cavea*, from its being sunk below the level of the stage.

PIT-*fish*, or PIT-*worfe*, in *Ichthyology*, the Dutch name of an East Indian fish, approaching very much to the nature of the European turdus, but that it has no scales; its body is not flat but rounded, and is variegated with blue and yellow spots; its eyes stand very prominent, and the fish is able, at pleasure, to thrust them out or draw them in; its back-fin is prickly: it loves muddy and foul places, yet is a very well tasted fish.

PITANCIARIUS, PITANCIARIUS, or PITANTIARIUS, an office, in the ancient monasteries, whose business it was to provide and distribute the pittances of herbs and meat amongst the monks. See PITTANCE.

PITANGUAGUACU, in *Ornithology*, the name of a Brasilian bird of the starling kind, called by the Portuguese there the *bemetevi*. It is of the size of the common starling; its beak is long, thick, and of a pyramidal figure; its head broad and flatted; its neck short, which as it lies it contracts also, so as to make it appear much shorter; its legs and feet are of a dusky brown; it has a very loud and shrill voice; its head, neck, back, wings, and tail, are all of a brownish black, with a faint admixture of green; the lower part of the throat, the breast, and the belly, are yellow, the upper part of the throat white; its beak is very sharp-pointed.

PITCH, PIX, a tenacious sort of juice, or gum, drawn from fatty woods, chiefly from pines and firs; and used in shipping, in medicine, and in various other arts.

Pitch is properly a juice of the wild PINE, or pitch-tree; and is conceived to be no other than the oil thereof inspissated, and turned black, farther than in the balsam. For the method of procuring it from the wood of this tree, see PINE.

The best is that brought from Sweden and Norway. Its goodness consists in its being of a glossy black colour, dry, and brittle.

This is less pungent and less bitter than the liquid TAR, and used only in some external applications, as a warm, adhesive, resinous substance. Neumann observes, that when melted with oils, resins, and fats, into ointments and plasters, the *pitch* is very apt to separate and precipitate.

The ancients had a peculiar kind of *pitch* called AMUSIA, which was inspissated to a higher than ordinary degree for certain uses; such as the receiving a proper quantity of bees wax, to render it the zopissa used in coating the bottoms of ships; which the common *pitch* could not do, being of too soft a consistence for this use. Pliny tells us that it was made in this manner: the wood was cleaved and formed into a pile, with proper trenches cut in the earth to receive what run from it in burning. When the pile was lighted, the first thing that flowed into these trenches was a thin fluid liquor like water.

PITCH-*tree*, in *Botany*. See PINE-*tree*.

PITCH, *Burgundy*, is brought to us from Saxony, and is supposed to be a preparation of the same kind with the common ROSIN of the shops, only less divested of the oil, made by boiling the common TURPENTINE till it acquires a due consistence.

PITCH, *naval*, *pix navalis*, is that drawn from old pines, ranged and burnt like charcoal. This, with a mixture of tow, or beaten cables, serves for the pitching of vessels.

PITCH, *mineral*, is also a denomination given to that scraped from off the sides of old vessels; and which is supposed to have acquired an astringent virtue, by means of the salt water. It serves to make plasters; though it is certain the apothecaries usually substitute the common *black pitch* in its stead.

PITCH, *Greek*, or *Spanish* PITCH, is that boiled in water till it has lost its natural smell; upon which it becomes dry and friable.

The ancients called it *colophane*; from Colophon, a city in Greece, whence great quantities were brought.

PITCH, *oil of*, *oleum picinum*, is an oil procured from *pitch*, by separating the aqueous matter that swims a-top of the melted *pitch*. This, for the great virtues attributed to it, is also called *balsam of pitch*.

PITCH, *ointment of*, in *Medicine*, is made by melting tar with an equal weight of mutton suet, and straining the mixture whilst hot: this is used sometimes as a digestive, and said to be particularly serviceable against scorbutic and other cutaneous eruptions.

PITCH, *pills of*, are made of tar mixed with so much powdered liquorice, or other such powdered matter as is sufficient to render it of due consistence for being formed into pills.

PITCH *of Castro*, in the *Materia Medica*, the name given by Boccone and some other writers, to a thick kind of bitumen found issuing out of the cracks of some rocks near the village of Castro; from whence it has its name: it is famous in the ecclesiastical state for its medicinal virtues.

PITCH, *Jew's*. See ASPHALTUM.

PITCH, in *Music*. See GRAVITY *of Sound*, and KEY.

PITCH, in *Building*, denotes the angle or GABLE-end.

If the length of each rafter be three-fourths of the breadth of the building, the roof is said to be *true pitch*. This is used when the covering is of plain tiles.

If the rafters be longer, it is said to be a *high* or *sharp-pitched* roof; if shorter, which seldom happens, it is said to be a *low* or *flat-pitched* roof.

If the length of the principal rafters be equal to the breadth of the building, it is called *Gothic pitch*. This is used when the covering is of pantiles.

If to rule as a pediment, it is said to be pediment *pitch*. The perpendicular height of this *pitch* is equal to $\frac{3}{8}$ of the breadth of the building. This *pitch* is used when the covering is lead.

PITCHED, in the *Sea Language*. They say the mast is *pitched*, when it is put or let down into the step: also the mast is *pitched* too far aft, when placed too near the stern. When a ship falls with her head too much into the sea, or beats against it so as to endanger her top-masts, they say, she will *pitch her masts by the board*.

This motion may proceed from two causes; the waves which agitate the vessel, and the wind upon the sails, which makes her stoop to every blast thereof.

PITCHING. See PAVEMENT.

PITCHING-*penny*, a duty, commonly of one penny, paid for *pitching* or setting down every sack of corn, or pack of merchandize, in a fair or market.

PITCHT, *boulder*. See SHOULDER *pitcht*.

PITH, in *Vegetation*, the soft spongy substance contained in the central part of plants and trees. As the substance of the trunk in trees become more woody, the *pith* is compressed and straitened to such a degree, that it wholly disappears.

It is plain from this, that the office of the *pith* in vegetation cannot be very great, since it is not of perpetual duration. By its spongy structure, it seems fitted to receive any superfluous moisture that might transude through the pores of the woody fibres. If by the excess of such moisture, or from any other cause, it happens to rot and perish, as frequently happens in elms, the tree is found to grow full as well without it; a proof it is of no essential use in vegetation. Boerhaave, Chem. p. 139.

The *pith* of trees is continued farther into their minute parts than is generally conceived; the smallest branches and pedicles of the leaves and flowers have their share of it, according to the nature of the tree they belong to; and even the middle ribs of the leaves, when examined by the microscope, are not without it: a transverse section of one of these ribs of the leaf of a *pith* tree shows a very beautiful arrangement of vessels, or little bladders, containing a quantity of clear liquor, and resembling in all respects those of which the *pith* in the branches is composed. The *pith* in these is not round, however, as in the others, but flat, and runs from one end of the pedicle to the other, in form of a thin white rib, gradually lessening to a point.

The *pith* of plants, in fine, seems what the marrow is in animals, a congeries of an infinite number of vesicles, which seem destined to separate a finer juice than is necessary for the nourishment of the coarser parts of the tree. It is observed of plants which have a larger than ordinary share of *pith*, that they produce larger quantities of flowers than others; instances of this are seen in the rose, the lilac, and the common elder: and in the fesculaceous plants, the quantity of flowers is not only profusely large, according to the great quantity of *pith* in their stalks; but the *pith* seems carried up the stalks all the way to the seeds themselves; the long seed [illegible] the sweet myrrhis, and other the like plants, which [illegible] being only *pith*. Mem. Acad. Scienc. 1705.

Dr. Hales shews that the *pith* serves to supply [illegible] moisture for the tender shoots of plants; and that the figure of these may be oblong, and not round. In the fruit, there are tough diaphragms, or partitions in the

pith

pith at small distances from each other, which check the lateral expansion; as also horizontal fibres, which serve for the same purpose.

Of the same sort is the *pith* in the large growing feathers of birds; being composed of vesicles that can be distended lengthways, but have sphincters at the ends, to prevent too large a lateral dilatation. Vid. Hales's Veget. Statics, vol. i. p. 337.

PITHECALOPEX, the *semivulpa*, or *apo-fox*, a name given by Aldrovandus and some others, to that strange American animal which we call the OPOSSUM.

The name is compounded of that of the *fox* and the *ape*; of the natures of both which animals it is supposed by some to participate.

PITHIA, and PYTHIAN. See PYTHIA, and PYTHIAN.

PITHOS, or PITHITES, with some writers, a sort of comet, or rather meteor, in form of a tub. Of these it is said there are divers kinds, viz. some of an oval figure, others like a tun or barrel set perpendicular, and some like one inclined, or cut short off; others having a hairy train or bush, &c.

PITHYUSA, in *Botany*, a name used by many authors for a small species of SPURGE.

PITT. See PIT.

PITTACIUM, *Tarbeam*, in *Surgery*, a name which some authors give to a piece of cloth spread with a salve, to be laid on a part affected.

PITTANCE, *portantia*, the common, or allowance of meat, be it fish, flesh, or the like, ftatedly eaten at meals, besides bread.

The word is not much used except among religious, and those who live in college, or community. Du-Cange derives it from *pittantia*, used in the lower Latin for a monachal portion given to two monks in the same dish, consisting of something better than pulse.

Hence we sometimes also find it denote a meal, or commons, better than ordinary; such as is allowed in communities on feast days.

Others derive the word a *pittate*; and others, with Salmasius, from *pittacia*, a mess, or portion, allowed the soldiers, mentioned in several laws of the Theodosian code. It is added, that the word *pittacia* properly signified a title, or written label, added a-top of the vessel, to shew what was within-side, or for whom it was intended.

PITUINA, in the *Materia Medica*, a name for the resin of the pitch-tree.

PITUITA, one of the four humours found in the bodies of animals, on which their temperament is commonly supposed to depend.

The *pituita*, called also *phlegm*, is properly the most viscid and gluinous part of the blood, separated in the largest glands, where the contortions of the arteries are greatest, and give the greatest retardation to the blood's velocity; as in the glands about the mouth and head.

The class of phlegmagogues, as manna, &c. are supposed particularly to purge *pituita*.

Physicians give several epithets to the *pituita*, according to its conditions, or qualities; as *saline*, *vitreous*, *gypseous*, *acid*, &c.

Pituita is supposed to be the prevailing humour in cold, heavy, slow people, inclined to seriousness and study; as the bile is in those inclined to war, &c.

The *pituita*, discharged at the nostrils, is separated in the membrane that lines the cavities of the nose, cheeks, &c. Its use is, to keep that membrane soft, and defend it from injuries of extraneous bodies, especially those of the air, which passes this way, in inspiration, when the mouth is shut.

PITUITARY *gland* is a gland in the brain, somewhat difficult to be seen without removing it out of its place; and of a singular kind of substance, which seems to be neither medullary nor glandular. In figure, it is transversely oval or oblong, and in the lower part in some subjects it is divided by a small notch with two lobes, like a kidney bean. See *Tab. Anat. (Angiol.) fig.* 1. *lit.* 6.

It is of the size of a very large pea, and is placed in the sella of the os sphenoides, under the infundibulum, wherewith it communicates; and covered by the pia mater as by a bag; receiving a lympha, or juice, which the infundibulum derives from the plexus choroides, and pineal gland; and from this lympha does the gland itself take its name.

It also filtrates a juice itself; separating from the blood a white liquor, very subtile, and apparently very spirituous.

M. Littre observes a sinus, or reservoir of blood, which touches this gland; and which is open to it in the place of contact, so that the gland lies partly in the blood. This, that author takes to do the office of a balneum Mariæ, in keeping the gland of the degree of warmth necessary for the discharge of its functions.

This gland is found in all quadrupeds, fishes, and fowls, as well as in men. M. Littre gives an instance of a tedious disease, and at length death, arising solely from an obstruction and inflammation of the *pituitary* gland.

PITUITARY *membrane*, is that which lines the whole internal nares, the cellular convolutions, the conchæ, the sides of the septum narium, and, by an uninterrupted continuation, the inner surface of the sinus frontales and maxillares, and of the ductus lacrymales, palatini, and sphenoidales. It is likewise continued down from the nares to the pharynx, septum palati, &c. It is so called, because it separates from the arterial blood a mucilaginous lympha called PITUITA.

This membrane is of different structure in different parts. Near the edge of the external nares it is very thin, in other places it is thick and spongy; it is thickest on the septum narium, the lower portion of the internal nares, and the conchæ: in the sinuses its texture is more slender; and on the side next the periosteum and pericbondrium it is furnished with many small glands. Winslow.

PITY, in *Ethics*. See COMPASSION.

PITYIDES, a name used by some authors for the kernels inclosed in the cones of the fir or pitch-tree; they are recommended by the old physicians, in disorders of the breast.

PITYLISMA, a name of one of the exercises described by the ancient physicians, as of great service in chronic cases. It consisted in a person's walking on tip-toe, and stretching his hands as high above his head as he could, keeping the whole body also as much upon the stretch as might be. In this condition the patient was to walk as far as he was well able, all the while moving about both hands as much as he could, in all directions.

PITYRIASIS, a name given by the ancients to a scurfy disorder of the head and eye-brows, and of any other part where there is hair. It makes the skin seem as if covered with bran, and is attended with a troublesome itching.

PIVA, in the *Italian Music*, a HAUTBOY or CORNET.

PIVOT, or PIVOT, a foot or shoe of iron, or other metal, usually conical, or terminating in a point; whereby a body intended to turn round, bears on another fixed at rest, and performs its circumvolutions.

The *pivot* usually bears or runs round in a sole or piece of iron or brass, hollowed to receive it.

Large gates, &c. usually turn on *pivots*. The ancients tell us, they had theatres in Rome, that held eighty thousand people, which yet turned on a single *pivot*.

PLACAGNODIAUGIA, in *Natural History*, the name of a genus of spars.

The word is derived from the Greek πλαξ, *a cruſt*, αγνυω, *pure*, and διαυγης, *pellucid*.

The bodies of this genus are cryſtalline terrene ſpars, or ſparry bodies with much of the brightneſs and tranſparence of cryſtal, but debaſed by an admixture of earthy matter, and are imperfectly pellucid, and formed into thin plates with flat ſurfaces, but covered at times either in part or entirely, with tubercles or botryoide prominences, and are compoſed of arrangements of oblong concretions, of no determinately angular figure.

Of this genus there are only two known ſpecies, viz. a hard ſemipellucid and yellowiſh brown one; and a brittle pellucid and whitiſh one. Hill.

PLACAGNOSCIERIA, in *Natural History*, the name of a genus of ſpars.

The word is derived from the Greek πλαξ, *a cruſt*, αγνυω, *pure*, and σκληρος, *opake*.

The bodies of this genus are dull and opake cryſtalline terrene ſpars, formed into cruſts, and of an irregular and not ſtriated texture within.

Of this genus there are three known ſpecies, viz. a hard whitiſh brown one, a dull crumbly whitiſh one, and a dull pale brown friable one, of a very coarſe texture, which encruſts the ſides and bottoms of veſſels, in which water is frequently boiled. Hill.

PLACARD, or PLACART, PLACAERT, a foreign term, frequent in Gazettes, ſignifying a leaf, or ſheet of paper, ſtretched and applied upon a wall, or poſt. Edicts, regulations, &c. are to be made public in *placards*.

The word *placard* is alſo uſed for a libel or lampoon. At Rome, *placards* againſt the pope are frequently fixed, in the night-time, to the ſtatue of Paſquin. See PASQUINADE.

PLACARD, in *Architecture*, denotes the decoration of the door of an apartment, which is ſometimes a corniche ſupported by conſoles.

PLACARD, in *Our Cuſtoms*, denotes a licence whereby a perſon is permitted to ſhoot with a gun, or to take otherwiſe unlawful game.

PLACE, *locus*, in *Philoſophy*, that part of immoveable ſpace which any body poſſeſſes.

Ariſtotle, and his followers, divide *place* into *external*, and *internal*.

PLAGE,

PLACE, *internal*, is that ſpace, or room, which the body contains.

PLACE, *external*, is that which includes or contains the body; which is alſo called, by Ariſtotle, the firſt or concave and immoveable ſurface of the ambient body.

It is controverted, in the ſchools, whether *internal place* be a real entity, or only an imaginary being; i. e. whether it be any thing intrinſically, or only an aptitude and capacity of receiving bodies.

Some maintain it a poſitive being, incorporeal, eternal, independent, and infinite; and aſſert it even to conſtitute the immenſity of the Godhead.

The Carteſians, on the contrary, hold *internal place*, abſtractedly conſidered, to be no other than the very extenſion of the bodies contained therein; and therefore in no wiſe different from the bodies themſelves.

The ſchoolmen likewiſe diſpute, whether *external place* be moveable, or immoveable? Its immobility is argued from this conſideration; that what moves, muſt neceſſarily leave its *place*; which it cannot do, if it go along with the moveable. Others charge an abſurdity on this opinion of Ariſtotle; viz. that hence it follows, that a body really at reſt is continually ſhifting *place*: a tower, for inſtance, on a plain; or a rock in the middle of the ſea; becauſe the one and the other are continually incloſed with new air, or new water, muſt be ſaid to be in motion, or to change *place*.

To ſolve this difficulty, and ward off the abſurdity which follows from Ariſtotle's laying down external place as immoveable, many expedients have been had recourſe to. The Scotiſts contend for *place*'s being only immoveable, by equivalence. Thus, when the wind blows, the air which inveſted the ſurface of the tower does indeed recede, but then other ſimilar and equivalent air takes place. The Thomiſts chuſe to deduce the immobility of *external place*, from its keeping the ſame diſtance from the centre, and the cardinal points of the world; and the Nominaliſts, from a correſpondence with certain virtual parts of the divine immenſity.

The Carteſians deny *external place* to be either a ſurrounding ſurface, or a body ſurrounded, or a mean term between the two; and conceive it to be the ſituation of a body among adjacent bodies conſidered as at reſt. Thus the tower muſt be deemed to remain in the ſame *place*, though the ambient air be changed; ſince it retains the ſame ſituation, with regard to the neighbouring hills, trees, and other parts of the earth.

Sir Iſaac Newton better, and more intelligibly, diſtinguiſhes *place* into *abſolute*, and *relative*.

PLACE, *abſolute*, and *primary*, is that part of infinite and immoveable ſpace which a body poſſeſſes.

PLACE, *relative*, or *ſecondary*, is the ſpace it poſſeſſes, conſidered with regard to other adjacent objects.

Dr. Clark adds another kind of *relative place*, which he calls *relatively common place*; and defines it, that part of any moveable or meaſurable ſpace which a body poſſeſſes; which *place* moves together with the body.

PLACE, Mr. Locke obſerves, is ſometimes likewiſe taken for the portion of infinite ſpace poſſeſſed by the material world, though this, he adds, were more properly called extenſion.

The proper idea of *place*, according to him, is the relative poſition of any thing, with regard to its diſtance from certain fixed points; whence we ſay, a thing has or has not changed *place*; when its diſtance is, or is not altered with reſpect to thoſe bodies.

For the viſion of *place*, ſee VISION, and VISIBLE.

PLACE, in *Optics*, or *Optical* PLACE, is the point to which the eye refers an object.

Thus the points D and E (*Tab. V. Optics. fig.* 89.) to which two ſpectators in *d* and *e* refer the object C, are called *optic places*.

Here, if a right line joining the optic *places* D and E, be parallel to a right line paſſing through the eyes of the ſpectators *d*, *e*; the diſtance of the optic *places* D, E will be to the diſtance of the ſpectators *d* and *e*, as the diſtance of one of the optic *places* from the *place* of the object EC, to the diſtance of the other ſpectator from the ſame object *d* C.

PLACE, *optic*, of a ſtar, is a point in the ſurface of the mundane ſphere as C or B (*Tab. Aſtronomy, fig.* 27.), wherein a ſpectator in E, or T, ſees the centre of the ſtar S.

This is divided into *true*, and *apparent*.

PLACE, *true*, or *real optic*, is that point of the ſurface of the ſphere B, wherein a ſpectator, placed in the centre of the earth, ſees the centre of the ſtar, or phenomenon.

Or it is a point among the fixed ſtars, determined by a line drawn from the centre of the earth through that of the ſtar, and terminated in B among the ſtars.

PLACE, *apparent*, or *viſible optic*, is that point of the ſurface of the ſphere, wherein a ſpectator, placed on the ſurface of the earth in E, ſees the centre of the ſtar S. Or a point C found by a line paſſing from the ſpectator's eye through the ſtar, and terminated in the ſphere of the ſtars.

The diſtance between the two optic *places* makes what we call the PARALLAX.

The *apparent place*, in optics, is different from the *real* one; for when, by refraction through glaſſes, that parcel of rays which falls on the pupil of the eye, from each point of any near object, is made to flow as cloſe together, as that which comes from a diſtant one; or when, by the ſame means, the rays coming from diſtant objects are made to diverge as much as if they flowed from near ones; then the eye muſt neceſſarily ſee the *place* of the object changed; which change is its *apparent place*.

If an object be placed nearer to a convex glaſs than is the diſtance of its focus, its *apparent place* may be determined: but if the object be in the focus of the glaſs, the *locus apparens* of the object cannot be determined; only that it will appear vaſtly remote.

Nor can the *locus apparens* be determined if the object be beyond the focus of a convex glaſs: but if the object be farther diſtant from a convex glaſs than its focus, and the eye lie beyond the diſtinct baſe, its *apparent place* will be in the diſtinct baſe. See LENS.

PLACE *of the ſun*, a *ſtar*, or *planet*, ſimply, denotes the ſign and degree of the zodiac, which the luminary is in.

Or, it is that degree of the ecliptic, reckoned from the beginning of Aries, which the planet's or ſtar's circle of longitude cuts: and therefore it coincides with the longitude of the ſun, planet, or ſtar.

As the ſine of the ſun's greateſt declination 23° 30': to the ſine of any preſent declination given or obſerved, v. gr. 23° 1' 12" ſo is radius 10: to the ſine of his longitude 80° 53', which, if the inclination were north, would give 20° 51' of Gemini, if ſouth, 20° 52' of Capricorn, for the ſun's *place*.

PLACE, *aphrontical*. See ASTRONOMICAL.

PLACE, *mean*, is that point of her orbit wherein ſhe is found at any time.

This, by reaſon of the great inequalities in the lunar motions, which render a number of equations and reductions neceſſary before the juſt point be found, is of various kinds; viz. her *fictitious place*, which is the moon's *place* once equated; her *place mean in anno*, which is her *place* twice equated; and the moon's *true place*, which is her *place* thrice equated.

PLACE, *excentric*, *of a planet in its orbit*. See ECCENTRIC, and E, *Tab. Aſtron. fig.* 26.

PLACE, *heliocentric*, of a planet. See HELIOCENTRIC, and R, *fig.* 26.

PLACE, *geocentric*. See GEOCENTRIC, and R, *fig.* 26.

PLACE, *computation of a planet's*. See PLANET.

PLACE *of radiation*, in *Optics*, is the interval, or ſpace in a medium or tranſparent body, through which any viſible object radiates.

PLACE, in *Geometry*, is a line uſed in the ſolution of problems; more uſually called by the Latin name, *locus*.

See the doctrine of geometrical *places* under LOCUS; ſee alſo PLANE.

PLACE, in *War*, is a general name for all kinds of fortreſſes, where a party may defend themſelves.

In which ſenſe it may be defined to be a *place* ſo diſpoſed, as that the parts which encompaſs it defend and flank one another.

PLACE, *ſtrong*, or *fortified*, is a *place* flanked and covered with baſtions. See FORTIFIED *place*.

PLACE, *regular*, is that whoſe angles, ſides, baſtions, and other parts are equal; and this is uſually denominated from the number of its angles: as a pentagon, a hexagon, &c. Palma Nova, built by the Veneſians, is a dodecagon.

PLACE, *irregular*, is that whoſe ſides and angles are unequal.

PLACE *of arms*, in *Fortification*, is a ſtrong city or town, pitched upon for the chief magazine of an army. See *Tab. II. Fortific. fig.* 21. *lit.* ſſ, &c. and *Tab. VII. fig.* 38.

PLACE *of arms*, in a *city* or *garriſon*, is a large open ſpot of ground, uſually near the centre of the place, where the grand guard is commonly kept, and the garriſon holds its rendezvous at reviews, and in caſes of alarm, to receive orders from the governor.

PLACE *of arms*, of an *attack*, in a ſiege, is a ſpacious place covered from the enemy by a parapet or epaulement, where the ſoldiers are poſted ready to ſuſtain thoſe at work in the trenches, againſt the ſoldiers of the garriſon. It is cuſtomary to make three *places of arms*, when the ground will permit; the firſt and moſt diſtant from the place is about three hundred toiſes from the glacis of the covert way; the ſecond is within one hundred and forty toiſes: and the third at the foot of the glacis. See PARALLELS.

PLACE *of arms particular*, in a *garriſon*, is a place near every baſtion, where the ſoldiers, ſent from the grand

place to the quarters assigned them, relieve those that are either upon the guard, or in fight.

PLACE *of arms without*, is a place allowed to the covert-way, for the planting of cannon; to oblige those who advance in the approaches to retire.

Those *places of arms* that are in the covered way, are places made at the entering and saliant angles, considerably larger than the street of the covered way, and formed by turning the head of the glacis into two faces, projecting towards the country: those at the saliant angles are formed by the rounding of the counterscarp; those at the entering angles are constructed by taking the gorget at the head of the glacis of a certain length, drawing the faces at a certain angle, and parallel to those faces drawing a glacis. See FORTIFICATION *according to M. Vauban, and according to M. Cochorn.*

PLACE *of arms*, in a camp, is properly the bell-tents at the head of each company, where the arms are lodged. Italso denotes a large space at the head of the camp, for the army to be ranged in and drawn up in battalia.

PLACE *of arms* of a troop or company, is the spot of ground on which the troop, or company, draws up.

PLACE, *face of a*. See FACE.

PLACE, *tenaille of the*. See TENAILLE.

PLACE, *view of a*. See VIEW. See FORTIFICATION, *according to M. Vauban's first method.*

PLACE, *fire*. See FIRE-PLACES.

PLACE, among *Logicians* and *Orators*, denotes the seat or source of an ARGUMENT; or that from which it is taken.

PLACE is used in the doctrine of artificial memory; and these *places* may be either such in a proper sense, as a door, a window, a corner, &c. or familiar and known persons; or any thing at pleasure, provided they be placed in a certain order, animals, plants, words, letters, characters, historical personages, &c. though some of these are more and some less fit for the purpose; but such kinds of *places* greatly help the memory, and raise it far above its natural power. See MEMORY.

PLACE, *common*. See COMMON *place*.

PLACE *of units, tens, &c.* See UNIT, and NUMERATION.

PLACES, *topical*, in *Astrology*. See HYLEGIAL.

PLACE, *whispering*. See WHISPERING.

PLACE, *additions of*. See ADDITION.

PLACE, *unities of*. See UNITY.

PLACE *bricks* were kiln-burnt red *bricks* of a full size, now entirely disused in the metropolis; but in lieu of them, the soft insufficiently burnt bricks from the outside of the clamps are called, by way of distinction from stock or hard burnt bricks, *place bricks*. These are of a foul red colour, and will easily break or crush to pieces. The particular manner in which *place bricks* were formerly made was by dipping the mould in water before the clay was put in; which made the outer surfaces which burnt very coarse and hard. See BRICK.

PLACENTA, in *Anatomy*, a soliſh roundiſh maſs, found in the womb of a pregnant woman; wherein the ancients ſuppoſe the blood was purified, and prepared for the nourishment of the fœtus. See *Tab. Anat. (Splanchn.) fig.* 16. *lit.* e e.

Hence they alſo called it *hepar uterinum*, the liver of the womb, as if it did the office of a liver in preparing the blood.

It is called by the moderns *placenta*, q. d. womb-cake, becauſe in form of a cake.

The *placenta* is ſuppoſed by ſome to be only a maſs of coagulated blood: for, in the preſſing or waſhing it, it diſſolves; and its real uſe to be, to ſerve as a pillow for the umbilical veſſels to reſt on.

Its figure is not unlike that of a plate without brims; it is uſually three-quarters of a foot over, and ſometimes a foot. It is round, and generally concave and convex; the convex ſide adheres to the uterus, and is uneven, having divers protuberances and pits, by which it makes impreſſions upon, and receives others from, the uterus. Its place in the uterus, whatever ſome pretend, is not certain.

In women, unleſs in caſe of twins, &c. there is but one *placenta*: however, the number generally anſwers the number of the fœtus. In ſome brutes, eſpecially cow or ſheep, they are very numerous, ſometimes near a hundred, even for one fœtus; but ſmall, and only reſembling large conglomerate glands. From the external or concave ſide, which likewiſe has its protuberances, though covered with a ſmooth membrane, iſſue the umbilical veſſels, which are in great plenty diſtributed through the whole ſubſtance of it.

Some even imagine this part to be no more than a plexus of the veins and arteries, by whoſe extremities opening into the ſides of the hypogaſtric veſſels, the circulation is performed between the mother and the fœtus: for that ſide of the *placenta* which adheres to the womb appears to be nothing but the extremities of an infinite number of ſmall threads, which, in labour, dropping out of the pores in the ſides of the hypogaſtric blood-veſſels, into which they had inſinuated themſelves, is the occaſion of the flowing of the lochia, till the uterus collapſes, or the *porus*, by the natural elaſticity of the veſſels, contracts by degrees.

It is a great diſpute among the anatomiſts of the Royal Academy of Paris, whether the *placenta* have any external coat, whereby it is connected to the womb? M. Mery maintains it has none, and that nothing hinders the blood of the mother from paſſing out of the womb into the *placenta*, and thence to the fœtus: in which opinion he is ſeconded by M. Rohault. Meſſ. Vieuſſens and Winſlow maintain the contrary. In a ſubſequent memoir, M. Rohaule endeavours to ſhew, that the *placenta* is no particular part, but only a portion of the CHORION condenſed or thickened.

The *placenta* has generally been looked upon as an original part among the ſecundines; but according to Dr. Thomas Simſon of St. Andrew's, it ſeems to have no place in the ovarium, nor in the uterus, *till* once the ovum becomes contiguous to the fundus, and then every contiguous part becomes really a *placenta*. He thinks the fundus uteri, a place peculiarly fitted for the growth of the *placenta*, as proper ſoils encourage the growth of the roots of trees and ſhrubs, many of which are propagated by the branches however placed; ſo that every part of them ſeems equally fitted to be root or branch. Hence he thinks extra-uterine conceptions can have no *placenta*; and he ſays, there are no inſtances in authors to contradict his opinion. The *placenta* does not increaſe in the ſame proportion which the fœtus does; for the ſmaller the fœtus is, the *placenta* is proportionably larger.

The *placenta* generally adheres to, or near the fundus of the womb, and is covered on the ſide next to the womb, with a fine membranous continuation of the chorion. Vid. Monro, Medic. Eſſ. Edinb. vol. ii. p. 128, and the authorities there quoted.

The ſeparation of the *placenta* from the womb muſt produce abortions, and this may be occaſioned by different cauſes operating in various manners, and requires very different treatment to prevent the loſs of the fœtus.

PLACENTA, in *Botany*, a term improperly given by Mr. Houſton, in the Philoſophical Tranſactions, N° 421, to what is uſually called *receptacle*. See RECEPTACULUM *ſeminum*.

PLACENTA, in *Natural Hiſtory*, the name of one of the claſſes of the echini marini. The characters of theſe are, that they are of a ſuperficial or plano-convex form, and are wrought in various ſhapes, as the paſſey pears: under theſe echini they all have a cinquefoil flower as their baſe, and their mouth is in the middle of the baſe; the aperture for their anus is uſually near the edge.

Of this claſs there are three genera: 1. The *orbicularis*. 2. The *cordiformis*. And 3. The *ovalis*. Which ſee under their ſeveral heads.

PLACENTA, among the *Ancients*, a kind of cheeſe-cake, the moſt ſimple kind of which was made of flour mixed with oil and cheeſe, to which honey was added: but the more luxurious ſort of people added likewiſe a great variety of herbs and fruits, as alſo ſugar, eggs, butter, &c.

PLACITA, PLEAS, a term frequent in our laws and coſtoms.

Originally, *placita* ſignified certain public aſſemblies, of all degrees of men, wherein the king preſided, and where the great affairs of the kingdom were conſulted upon.

Theſe aſſemblies were called *placita generalia*; becauſe *generalitas univerſorum majorum tam ecclesiarum quam laicorum ibidem convenebat*. And hence the decrees, ordinances, ſentences, &c. of this aſſembly, were alſo called *placita*.

Sim. Dunelmenſis tells us, they were held in the open fields; *ut, ſive lis, ſive quæſtio aliqua ſuperſit regem in literis ad ſuam curiam, quia ibi ea judicat in aperto, ubicunque curia ſua.*

Some will have theſe *placita generalia*, and *curiæ regis*, of ancient times, to be much the ſame with what we now call a *parliament*.

The lords courts came hence alſo to be called *placita generalia*, though oftener *curiæ generales*; becauſe all their tenants and vaſſals were obliged to appear in them.

We alſo meet with *placitum commune*, for the day appointed a criminal to appear in, and make his defence. Leg. Hen. I. And *placitum fractum*, i. e. when the day is lapſed.

Lord Coke derives the word *placitum à placendo; quia homines placitare ſuper omnia placet*: indeed, this ſeems a very fanciful etymon; and others have more reaſon in deriving the word from the German *platz*, or the Latin *platea*, *plateæ*, or *ſtratæ*, where theſe aſſemblies were originally held.

PLACITARE, in the *Old Law Books*, ſignifies to plead cauſes. See PLEADING.

Mos placitandi, ante Conquæstum, fuit coram aldermannis, & præpositis, & coram hundredariis, &c. baronibus, majoribus, maneriorum, seneschallis, & aschenis. Misc. in Bibl. Cottob. Tit. Vitellius.

Hence, *placitator*, a pleader. Ralph Flambard is recorded to have been *tetius regni placitator*, in William the Second's time.

PLACITUM, in *Law*, a sentence of the court; or an opinion, ordinance, or decree.

Curia PLACITORUM *coronæ*. See CURIA.

PLAFOND, or PLATFOND, in *Architecture*, the ceiling of a room, whether it be flat or arched; lined with laths and plaister, and sometimes also enriched with paintings, &c. See CEILING.

PLAFOND is also more particularly used for the bottom of the projecture of the larmier of the corniche; called also the SOFFIT.

PLAGIARY, in *Philology, author-theft*; or the practice of purloining other people's works, and putting them off for a man's own.

Among the Romans, *plagiarius* was properly a person who bought, sold, or retained a freeman for a slave; so called, because the Flavian law condemned such a person *ad plagas*, to be whipped.

Thomasius has an express treatise *de plagio literario*; wherein he lays down the laws and measures of the right which authors have to one another's writings. Dictionary-writers, at least such as meddle with arts and sciences, seem in this case to be exempted from the common laws of meum and tuum; they do not pretend to set up on their own bottom, nor to treat the reader at their own cost. Their works are supposed, in great measure, compositions of other people's; and whatever they take from others, they do it avowedly. In effect, that quality gives them a title to appropriate every thing that may be for their purpose, wherever they find it, and, they do no otherwise, than as the bee does for the public service.

Their occupation is not pilaging, but collecting contributions; and, if you ask them their authority, they will produce you the practice of their predecessors of all ages and nations.

PLAGIAULUS, Πλαγιαυλος, among the *Ancients*, a kind of FLUTE.

PLAGIOPLATEUS, in *Natural History*, a term used by Artedi and others to signify depressed, in opposition to the term CATHETOPLATUS, which signifies compressed.

PLAGIUM, in *Civil Law*, the offence of spiriting away and stealing men and children; whence the offenders were called plagiarii, and were punishable with death. See KIDNAPPING.

PLAGIURI, in *Natural History*, the name of one of the great classes, or families of fish; the characters of which are, that the tail is placed horizontally; they respire by means of lungs, and have usually a double fistule in the head; they are viviparous, and the males have a penis and testes, the females the vulva, ovaria, mammæ, &c. and they bring up their young with milk.

The term is derived from the Greek πλαγιος, *transverse*, and ουρα, *a tail*.

Dalechamp distributes all fish are comprehended the following genera: the physeter, delphinus, balæna, monodon, catodon, and thrichechus; which see under their respective articles.

PLAGUE, PESTILENCE, PESTIS, a very acute, destructive, malignant, and contagious disease; being a putrid fever in its worst degrees, and usually proving mortal.

The *plague* is commonly defined by a malignant fever; but Dickenbrock thinks the two ought to be distinguished: the fever not being the essence, but only a symptom or effect, of the *plague*.

The *plague* is reckoned by Dr. Lister, and many others, as an exotic disease, never bred or propagated in England, but always imported from abroad, and particularly from the Levant, the coasts of Asia the Less, Egypt, &c. where it is familiar. Sydenham observes, that it rarely infects England oftener than once in forty years; but through the mercy of God, it is now greatly beyond this period since we have been visited.

The origin and cause of the *plague* have been a celebrated subject of controversy among physicians. The disorder is generally supposed to be communicated by the air; but how, and in what manner, the air becomes thus deadly, is the question.

Some will have infects the cause of *plagues*, as they are of blights: these, they say, being brought in swarms from other parts by the winds, are taken into the lungs in respiration, mix with the blood and juices, and attack and corrode the viscera. Mr. Boyle, on the other hand, attributes *plagues* principally to the effluvia or exhalations breathed into the atmosphere, from noxious minerals.

The air, in effect, is depraved in far more places than improved by being impregnated with subterraneous expirations. Indeed a long the minerals known to us, there are many more noxious than wholesome ones; and the power of the former to do mischief is more efficacious than of the latter to do good, as we may guess by the small benefit men receive in point of health, by the effluvia of any mineral or other known fossil, in comparison of the great and sudden damage often done by the expirations of orpiment, sandarac, and white arsenic.

Amongst the various sorts of particles wherewith the atmosphere is replete, some may be so small and solid, or so conveniently shaped, as to enter many of the numerous orifices of the minute glandules of the skin, or at other pores thereof. Thus, though neither paper nor bladder be pervious to the elastic parts of the air; yet may either of them be easily penetrated by other corpuscles of the atmosphere; and Mr. Boyle says, he has prepared a dry body, which being inclosed in either, would, without wetting or discolouring, or any ways sensibly altering them, pass immediately through the pores thereof, in such plenty, as to exert a manifest operation on bodies placed at some distance beyond them.

This is also confirmed from the sudden check almost every summer given to the *plague* at Grand Cairo; for since morbific causes operate more effectually than curative ones, it seems more than probable, that exhalations ascending from under-ground may produce pestilential fevers, and the *plague* itself; since the corpuscles which impregnate the Egyptian air upon the swelling of the Nile, put a speedy stop not only to the contagion, but to the malignity of the *plague*, assisted even by the summer's heat, which is there excessive.

It is possible there may be noxious minerals in a country, that are not often able to produce pestilences; they may be in strata, or beds, so deep, that even a small earthquake shall not affect them, though a more violent stroke may.

And hence we may account for the *plague*'s raging in some parts of Africa once in thirty, or once in a hundred years; since there may be periodical paroxysms, or grand and vehement commotions in the subterranean parts, though not yet observed in them.

It is probable, peculiar kinds of venomous exhalations may sometimes be emitted, especially after earthquakes; and thus occasion mortal diseases in animals of one kind, and not of another; as in this or that place, and not elsewhere. It is very easy to conceive, that the air we breathe, which is the general repository of the various effluvia emitted, not only by minerals and metals, but by stagnant waters, putrifying substances of different kinds, burning bodies, breathing animals, &c. may on some particular occasions, become in a peculiar degree noxious and fatal. How this effect is produced the reader will be able to perceive by consulting the articles AIR, DAMP, EFFLUVIA, PHLOGISTON, PUTREFACTION, &c.

Fernelius gives us an account of a *plague*, or murrain, in 1546, which invaded no creatures but oxen. Thomas Hollerianthus mentions a *plague*, which attacked none but mares; and that which raged in the time of Gemelin, killed scarce any women, and very few but fatter men. Boterus mentions another *plague*, which assaulted none but the younger sort; and we have instances of the same kind of a hasty handing. Cardan speaks of a *plague* at Basil, with which the Switzers, and not the Italians, Germans, or French, were infected; and Joh. Utenhovius takes notice of a cruel *plague* at Copenhagen, which, though it raged among the Danes, spared the Germans, Dutch, and English, who went with all freedom, and without the least danger, to the houses of the infected.

The *plague*, according to Sydenham, usually begins with a chilliness and shivering, like the accets of an intermitting fever; then comes on a nausea, with vehement vomitings; an intense pain about the region of the heart, as if pinched in a press; and a burning fever, which continually preys on the patient, till either death, or the eruption of some bubo, parotis, or other tumor, in the inguina or axillæ, or behind the ears, relieve him, and discharge the matter of the disease. Sometimes, indeed, it attacks without any fever; purple spots appearing all at once, the certain signs of present death; but this rarely happens except at the beginning of some terrible *plague*.

It has also been known to make its first appearance in tumors, without any fever, or other violent symptom.

Heaviness, pain in the stomach, head, and back, cardialgy, broken sleep, anxiety, alteration in the look, difficulty of breathing, hoccough, syncope, delirium, convulsive twichings, diarrhœa, eyes sunk or inflamed, tongue black and dry, vehement drought, fœtid breath, carbuncles, spots livid, purple, green, &c. are also symptoms usually attending this disease.

A great deal depends on the circumstances of the tumors, or *plague-sores*; as they appear and increase, the fever abates; and as they sink or diminish, it renews again. When they happen about the time of the crisis, and suppurate kindly, they are good prognostics of a happy recovery.

In acute diseases, says Hippocrates, prognostics are ever fallacious.

fallacious. However, in the terrible *plague* at Nimeguen, Diemerbroe who attended the sick through the whole progress of the disease, relates, that those taken ill about new and full moon rarely escaped; that faintings, sweatings, and palpitations of the heart, were usually deadly signs; an intermitting pulse always mortal; drowsiness, sneezings, tremulous motions, dosing, sore throat, &c. were ill omens: diarrhœas always mortal; costiveness a good sign: a diarrhœa almost constantly fatal; and that bloody stools or urine always presaged ill.

As to the cure, physicians are much divided. It is generally attempted with alexipharmics and cardiacs, with the assistance either of sudorifics, or phlebotomy, or both. Many eminent physicians, both ancient and modern, highly commend blood-letting; Sydenham particularly says, that if used copiously, and in time, it never yet did harm: but that sudorifics often prove pernicious. Diemerbroek, on the contrary, with other very experienced writers, protests against phlebotomy, as very dangerous, and often deadly; the chief hopes they founded on diaphoretics and sudorifics: emetics and purgatives are by most absolutely forbid; and yet Dr. Sayer used the former with good success, in the beginning of the disease in the *plague* at London, Ann. 1640. See ALEXIPHARMIC, &c.

The juice of lemons is commended, if singular efficacy in the *plague*, and pestilential severs: Piso relates, that it is the principal remedy of the Indians; and protests he never knew any thing come up to it. Dr. Harris observes, that the same remedy is what the Turks have principally recourse to. Camphor is also much extolled; this, Etmuller assures us, was the basis of Heinsius's antipestilential oil, who had a statue erected to him, when dead, in the city of Verona, for the service he had done thereby. It was prepared from equal quantities of camphor, citron-peel, and amber. The viperine salt, and rob of elder-berries, are also greatly commended.

For preservatives against the *plague*, they are usually summed up in that popular distich:

Hæc tria habitetur tollant adverbia pestem:
Aufer, longe, tarde, cito, procul, ride.

Cauteries, and especially issues, and setons in the inguins, are found of great service in preserving from infection. A piece of myrrh, held in the mouth in contagious places, is also commended. But Diemerbroek assures us, that there is nothing better to this intention, than smoking tobacco; but he adds, that it is only to such as have not made the practice familiar to them. The other preservatives used by that author were the rad. helenii, cardamoms, white-wine vinegar, and cheerfulness; and when he found his spirits low, as if the disease were taking possession, a cup of generous wine sometimes, even to a degree of ebriety. See *Pestilential* DISEASES, and EPIDEMIC.

Dr. Dover says he cured the *plague* among some sailors, in a voyage, by one very plentiful bleeding to the quantity of a hundred ounces, and with drink sharpened with spirit and oil of vitriol. Mem. Ed. Edinb.

Mayors, bailiffs, head officers of corporations, and justices of peace have power to tax inhabitants, houses, and lands, &c. within their precincts, for the relief of persons infected with the *plague*; and justices of the county may tax persons within five miles round, on a parish's inability; the taxes to be levied by distress and sale of goods, or in default thereof by imprisonment. Infected persons going abroad after being commanded to keep house for avoiding further infection, may be resisted by watchmen, &c. and punished as vagrants, if they have no sores upon them; and if they have infectious sores on them it is felony. Justices of peace, &c. are to appoint searchers, examiners, and buriers, of the dead, in places infected, and administer oaths to them for the performance of their duties, &c. 1 Jac. 1. cap. 31. See QUARENTINE.

PLAGUE-*water aqua epidemica*, is one of the compound waters of the shops, distilled from mint, rosemary, angelica roots, &c.

PLAIN, *planus*, an epithet applied to various things, generally importing them to be smooth, even, level, or superficial, or simple, or obvious, or the like.

In these senses the words stand opposed to rough, solid, laboured, enriched, &c.

It is a maxim in heraldry, that the *plainer* the coat, the nearer to antiquity. *Plain* coats are such as are least incumbered with figures, or charges, and which have nothing in them but what is natural.

PLAIN *figure*, in *Geometry*, is an uniform surface, from every point of whose perimeter, right lines may be drawn to every other point in the same.

Or, it is a figure which lies evenly between its bounding lines; and as a right line is the shortest extension from one point to another, so a *plain surface* is the shortest extension from one line to another.

PLAIN *angle* is an angle contained under two lines or surfaces.

It is so called in contradistinction to a *solid* angle.

PLAIN *triangle*, is a triangle included under three right lines, or surfaces; in opposition to a *spherical*, and a *mixt* triangle.

PLAIN *trigonometry* is the doctrine of plain triangles, their measures, proportions, &c.

PLAIN *glass*, or *mirror*, in *Optics*, is a glass or mirror whose surface is flat, or even. See the phenomena and laws of *plain* mirrors, under the article MIRROR.

PLAIN *style*. See DIAL.

PLAIN *scale* is a thin ruler, whereon are graduated the lines of chords, sines, tangents, secants, leagues, rhumbs, &c. of ready use in most parts of the mathematics, chiefly in navigation.

See its description and use under SCALE.

PLAIN *chant*, in *Music*. See CHANT.

PLAIN *descant*. See DESCANT.

PLAIN *chart*, in *Navigation*, is a sea-chart, wherein the meridians and parallels are represented by parallel straight lines; and where, of consequence, the degrees of longitude are the same in all the parallels of latitude.

See the properties, construction, &c. of this chart under CHART.

PLAIN *sailing*, in *Navigation*, is the art of working the several cases and varieties in a ship's motion on a *plain* CHART.

Plain sailing is founded on the supposition of the earth being a plane or flat; which though notoriously false, yet, places being laid down accordingly, and a long voyage broken into many short ones; the voyage may be tolerably performed by it, near the same meridian.

In *plain sailing* it is supposed that by the rhumb line, meridian, and parallel of latitude, there always will be formed a right-angled triangle; and that so posited, as that the perpendicular side may represent part of the meridian, or north and south line, containing the difference of latitude; the base of the triangle represent the departure; and the hypothenuse, the distance sailed. The angle at the vertex is the course, and the angle at the base, the complement of the course; any two of which, with the right angle, being given, the triangle may be protracted, and the other three parts found.

For the doctrine of *plain sailing*, see SAILING.

PLAIN *table*, in *Geometry*, &c. an instrument used in the surveying of land; whereby the draught, or plan, is taken on the spot, without any future protraction, or plotting.

The *plain table*, represented *Tab.* II. *Surveying*, *fig.* 34. consists of a parallelogram of wood, about fifteen inches long and twelve broad; round this goes a boxen jointed frame, by means whereof a sheet of paper is fastened right to the table, so that lines may be conveniently drawn upon it.

On each side the frame, which may be put on either side upwards, towards the inward edge, are scales of inches subdivided, for the ready drawing of parallel lines. Beside which, on one side are projected the 360 degrees of a circle, from a brass centre in the middle of the table (each degree halved) with two numbers to every tenth degree, the one expressing the degree, the other its complement to 360, to save subtraction: on the other side are projected the 180 degrees of a semicircle, from a brass centre in the middle of the table's length, and at ¼ of its breadth; each degree halved, and every tenth noted with two numbers, viz. the degree and its supplement, to 180°.

To one side of the table is fitted a compass, for placing the instrument by; and the whole is fixed by a socket, upon a three-legged staff for a stand, on which it is turned round, or fastened by a screw, as occasion requires.

Lastly, to the table belongs an index, which is a ruler at least fifteen inches long, and two broad; usually graduated with scales, &c. and having two sights perpendicularly placed on its extremities; and a sloped edge called the fiducial edge.

PLAIN *tables, use of the*. To take an angle by the *plain table*: or to find the distance of two places accessible from the same third.

Suppose D A, D B (*Tab. Surveying, fig.* 35.) the sides of the angle required; or A B the distance required. Place the instrument horizontally, as near the angle as possible; and assume a point in the paper on the table, v. gr. *a*. To this point apply the edge of the index, turning it about this and that way till through the sights you see the point B; and, in this situation of the ruler, draw by its edge the line *c c* indefinitely.

After the same manner turn about the index on the same point till through the sights you see the point A; and draw the right line *e d* indefinitely. Thus have you the quantity of the angle laid down.

Measure the lines D A, D B, with a chain; and from a scale

scale set off the measures thus found, on the respective lines; which suppose to reach from *c* to *A*, and from *c* to *o*. Thus will *cb* and *ca* be proportional to DB and DA. Transfer the distance *ab* to the same scale, and find its length; the length, thus found, will be the length, or distance of AB required.

2. *To find the distance of two places, one whereof is inaccessible, by the* plain table. Suppose the distance required AB (*fig.* 36.) and A the accessible point. 1. Place the *plain table* in C; look through the sights till you see A and B; and draw *ac* and *cb*. Measure the distance from your station to A; and set it off from the scale upon *ca*. 2. Remove the table to A, where place it so as that the point *a* representing A, and the index laid along the line *ac*, you see backwards the former station C (Note, in this fixing the instrument, lick the use of the compass; for the needle will hang over the same degree of the card in the first and the second case; so that some set the instrument by the needle alone; others only use it to shorten the trouble, by bringing the instrument nearly to its due position by means thereof; and then fixing for good by the back sight). 3. The instrument fixed, turn the sights to B, and draw the line *ab*. 4. On the scale measure the interval *ab*; which will be the distance of AB required.

3. *To find the distance of two inaccessible places by the* plain table. Suppose the distance of AB (*Tab. Surveying, fig.* 37.) required. 1. Choosing two stations in C and D, in the line, C, place the *plain table*; and through the sights look to D, B, and A, drawing, by the edge of the index the lines *cb*, *ca*, *cd*. 2. Measure the distance of the stations CD; and set this off from a scale on *cd*. 3. Removing the table from C, fix it in D; so as the point *d*, hanging over the place D, and the index lying along the line *dc*, through the sights you see the former station C. The instrument thus fixed, direct the sights to A and B, and draw the right lines *da* and *db*; lastly find the distance of *a* *b* on the scale, and this will be the distance of AB required. After the same manner may the distance of any number of places be found from two stations; and thus may a field, part of a country, &c. be surveyed.

4. *To take the plot of a field from one station, whence all the angles may be seen, with the* plain table. Placing the instrument in the station, assume a point in the paper, to represent the same, v. gr. O (*Tab. Surveying, fig.* 8.) laying the edge of the index to this point, direct it to the several angles of the field, ABCDEF, &c. and draw indefinite lines by its edge towards every angle; viz. O*a*, O*b*, O*c*, &c. measure the distance of each angle from the station; viz. OA, OB, OC, OD, &c. and from a scale set these off from O on their corresponding lines; the extremities hereof will give points, which, being connected by lines, will represent the field.

5. *To take the plot of a field, round, or the like, by going round the same, with the* plain table. Place the instrument horizontally at the first angle, v. gr. A; the needle being on the meridian of the card; assuming a point on the paper, to represent it; to that point lay the index, directing it till through the sights you see a mark in the angle B, and draw an indefinite line along it; measure the distance of A and B, and from a scale set it off on the line thus drawn; the extremity of this distance will represent the point B. Remove the instrument to B, where fix it so as that the needle hang over the meridian of the card; and so as the index lying along the line last drawn, you see the former station A through the sights: here fasten it, lay the index to the point B, and turn it till through the sights you see the next angle C, in this situation draw a line, as before, measure the distance BC, and set it off from a scale on the line. Remove the instrument to C, where, fixing it by the needle, and the back sight, as before, turn the index on the point C till you see the next angle D; draw the line, measure and set off the distance CD, as before, and remove the *plain table* to E; where fix it, as before; look in the next angle F, draw the line, measure and set off the distance, &c.

In this manner having compassed the whole field, you will have its whole perimeter plotted on the table; which may be now cast up, and its contents found, as in the article SURVEYING.

Manner of shifting paper on the plain table. When in large parcels of grounds the plot is found to exceed the dimensions of the plain *table*, and to run off from the paper, the sheet must be taken off the table, and a fresh one put on: the way of managing which shifting is as follows: suppose H, K, M, Z, (*Tab.* III. *Surveying, fig.* 41.) the limits of the *plain table*; so that having laid down the field from A to B, thence to C and D; you want room, the line DE running off the paper; draw as much of the line DE as the paper will well hold; viz. DO. And by means of the divisions on the edge of the frame, draw the line PQ through O, parallel to the edge of the table HM; and through the point of intersection O, draw ON parallel to MZ. This done, take off the frame, remove the sheet, and put a fresh one (*fig.* 42.) in its stead; drawing on it a line RS near the other edge parallel thereto. Then lay the first sheet on the table, so that the line PQ lie exactly on the line RS, to the best advantage, as at O. Lastly, draw as much of the line OD, on the fresh sheet, as the table will hold; and from O continue the remainder of the line D to E. From E proceed with the work as before to F, G, and A.

Use of the plain table, *as a theodolite, semicircle, or circumferentor.* The great inconveniency of the *plain table* is, that its paper renders its use impracticable in moist weather. Even the dew of the morning and evening is found to swell the paper considerably, and, of consequence, to distort the work. To avoid this inconvenience, and render the instrument useful in all weathers; by leaving off the paper, and fetting up a pin in the centre, it becomes a theodolite, a semicircle, or a circumferentor, and is applicable like them.

The *plain table*, ſtripped of its paper, becomes either a theodolite, or a ſemicircle, as that ſide of the frame, which has the projection of the degrees of a circle, or a ſemicircle, is turned upwards. *It is be to* ſerve for a theodolite; then index (the *plain table* turning on any point as a centre) is conſtantly to turn about the braſs centre-hole in the middle of the table.

If it be for a ſemicircle, it muſt turn on the other braſs centre-hole; in both caſes it is done by reaſon of a pin rivited in the holes. When the *plain table* is to ſerve as a circumferentor, ſcrew the compaſs to the index, and both of them to the head of the ſtaff, with a braſs ſcrew-pin fitted for the purpoſe; ſo that the ſtaff and table may ſtand fixed, the index, ſights, &c. may be eaſily moved, and *vice verſa*.

To take an angle by the plain table, *conſidered as a theodolite.* Suppoſe the quantity of the angle EKG (*Tab. Surveying, fig.* 6.) required. Place the inſtrument at K, ſo that the theodolite ſide of the frame upwards, laying the index on the diameter. Turn the whole inſtrument about, the index remaining on the diameter till through the ſights you ſpy E. Screw the inſtrument faſt there, and turn the index on its centre till through the ſights you ſpy G. The degrees here cut on the frame by the index, is the quantity of the angle ſought; which may be laid down on paper by the rules of common protraction.

Thus you may proceed to do every thing with the *plain table*, as with the common theodolite.

To take an angle with a plain table, *conſidered as a ſemicircle.* Proceed in the ſame manner with the inſtrument conſidered as a ſemicircle, as when conſidered as a theodolite; only laying the ſemicircular ſide of the frame, and turning the index on the other centre-hole in the middle of the length, and at about one-fourth of the breadth of the table.

To take an angle with the plain table, *conſidered as a circumferentor.* Suppoſe the former angle EKG required. Place the inſtrument at K, the fleur-de-lis towards you. Direct the ſights to E, and obſerve the degree cut by the ſouthend of the needle, which ſuppoſe 296. Turn the inſtrument about, the fleur-de-lis ſtill towards you, and direct the ſight to G, noting the degree cut by the other end of the needle, which ſuppoſe 32. Subtract the leſs from the greater, the remainder 264° is the quantity of the angle ſought. If the remainder chance to be more than 180°, then it muſt be again ſubtracted from 360. This ſecond remainder will be the angle required; which may be protracted, &c. as under PROTRACTOR.

Thus you may proceed to do every thing with the *plain table*, as with the common circumferentor.

PLAIN *number*. See NUMBER.

PLAIN *place*, in *Geometry*, *locus* PLANUS, or *locus ad* PLANUM, is a term which the ancient geometricians uſed for a geometrical locus, when it was a right line, or a circle, in oppoſition to a ſolid place, which was an ellipſis, parabola, or hyperbola.

Theſe *plain loci* the moderns diſtinguiſh into *loci ad rectum*, and *loci ad circulum*. See LOCUS.

PLAIN *problem*, in *Mathematics*, is ſuch a one as cannot be ſolved geometrically, but by the interſection either of a right line and a circle, or of the circumferences of two circles.

Such is the problem following. Given, the greateſt ſides, and the ſum of the other two ſides, of a right-angled triangle; to find the triangle. Such alſo is this, to deſcribe a trapezium that ſhall make a given area of four given lines.

Such problems can only have two ſolutions, becauſe a right line can only cut a circle, or one circle cut another in two points.

PLAIN, in *Heraldry*, is ſometimes uſed for the point of the ſhield, when coupled ſquare, a part remaining under the

the square, of a different colour, or metal, from the shield.

This has been sometimes used as a mark for bastardy, and called *champayne*: for when the legitimate descendants of bastards have taken away the bar, fillet, or traverse, borne by their fathers, they are to cut the point of the shield with a different colour, called *plain*.

PLAIN, used substantively, in *Perspective*, *Mechanics*, *Astronomy*, &c. See PLANE.

PLAINT, PLAINTE, in *Law*, the propounding or exhibiting any action, real or personal, in writing.

Hence, the party inveighing against, is called plaintiff.

PLAINTE, in the *Antient Customs of France*, was a request, or petition, presented to the king, against the judges of the provinces, and afterwards against bailiffs and seneschals, for denying justice, or for rendering judgment contrary to the laws of the realm.

For in those days there was no appeal from their decisions; but they all pronounced in the dernier resort; so that the *plainte* was not directed against the party, but against the judge; who was cited to see his own sentence declared null.

This was a kind of supplement to the way of appeals, which was then but up. The *plaintes*, in the Capitulars of Charlemagne, are called *querimoniæ*.

PLAINTIFF, in *Law*, he that sues, or complains, in an action, or in an action personal; as in an action of debt, trespass, deceit, detinue, and the like.

Plaintiff stands opposed to *defendant*.

PLAISE, in *Ichthyology*, the English name for the fish called by authors *platessa* and *passer laevis*, by some *quadratulus*, and the PLEURONECTES *platessa* of Linnæus.

It is, according to the Artedian system, a species of the pleuronectes, and is distinguished by that author by the name of the *pleuronectes* with smooth sides, and with a spine near the anus, and the eyes and six tubercles placed on the right side of the head.

It is a flat fish, of a dusky olive-colour, spotted with red on the back, and white on the belly.

The *plaise* are common on most of our coasts: the best and largest are taken off Rye, on the coast of Sussex, and also off the Dutch coasts. They spawn in the beginning of February.

PLAISTER, in *Building*. See PLASTER, MORTAR, &c.

PLAISTER, *casting in*. See CASTING.

PLAISTER, in *Medicine*. See EMPLASTER, and PLASTER.

PLAISTERED *walls*. See WALL.

PLAN, a representation of something, drawn on a plane.

Such are maps, charts, and ichnographies.

PLAN, in *Architecture*, is particularly used for a draught of a building; such as it appears, or is intended to appear, on the ground; shewing the extent, division, and distribution of its area into apartments, rooms, passages, &c.

The *plan* is the first device or sketch the architect makes; it is also called the *ground plot*, *platform*, and *ichnography*, of the building.

PLAN, *geometrical*, is that wherein the solid and vacant parts are represented in their natural proportion.

PLAN, *raised*, is that where the elevation, or upright, is shewn, upon the geometrical plan, so as to hide the distribution. See ELEVATION.

PLAN, *perspective*, is that conducted and exhibited by degradations, or diminutions, according to the rules of perspective.

To render *plans* intelligible, it is usual to distinguish the massive with a black wash. The projectures on the ground are drawn in full lines, and those supposed over them in dotted lines. The augmentations or alterations to be made are distinguished by a colour different from what is already built; and the ruins of each *plan* are made lighter as the stories are raised.

In large buildings, it is usual to have three several *plans* for the first three stories.

PLAN *of a fortification*, in the *Military Art*, is the same with the FACE of a *bastion*.

PLANCHER, or PLANCHER, in *Architecture*, the under part of the corona, or drip; making the superior part of the cornice, between two cymatiums.

PLANE, *planum*, in *Geometry*, denotes a *plain* figure, or a surface lying evenly between its bounding lines.

Wolfius defines *plane*, a surface, from every point of whose perimeter a right line may be drawn to every other point in the same.

As the right line is the shortest extent from one point to another, so is a *plane* the shortest extention between one line and another.

PLANE, *oblique*. See OBLIQUE.

PLANE, *parallel*. See PARALLEL.

PLANES are frequently used in *Astronomy*, &c. for imaginary surfaces, supposed to cut, and pass through, solid bodies, and on this foundation it is, that the whole doctrine of conic sections, and of the sphere, turns.

When a *plane cuts* a cone parallel to one of its sides, it makes a parabola; when it cuts the cone parallel to its base, it makes a circle.

The sphere is wholly explained by *planes*, imagined to cut the celestial luminaries, and to fill the areas or circumferences of the orbits; and they are differently inclined to each other; and by us the inhabitants of the earth, the *plane* of whose orbit is the *plane* of the ecliptic, their inclination is estimated with regard to this *plane*. See PLANETS.

PLANE, in *Mechanics*. A *horizontal* PLANE is a *plane* level or parallel to the horizon.

The determining how far any given *plane*, &c. deviates from a horizontal one makes the whole business of LEVELLING.

PLANE, *inclined*, in *Mechanics*, is a *plane* which makes an oblique angle with a horizontal *plane*.

A machine has been contrived for measuring the acceleration of a ball down an inclined *plane*, and comparing it with that found in bodies falling at liberty. See its description in Mem. de l'Acad. Roy. de Scienc. 1699, p. 343.

The doctrine of the motion of bodies on *inclined planes* makes a very considerable article in mechanics: the general principle of it has been already illustrated under MECHANICAL *powers*; and the substance of it is as follows:

Laws of descent of bodies on inclined planes. I. If a body be placed on an *inclined plane*, its relative gravity will be to its absolute gravity, as the height of the *plane*, *e.g.* AB (*Tab.* VI. *Mechan. fig.* 91.) to its length AC. For, the construction being as in the figure, it is evident that the absolute gravity, tending in a direction to the horizon, is to the relative gravity in the direction of the *plane*, as DF: FG or DE, *i.e.* because the triangles DEF and BAC are conjangular, as CA: AB.

Hence, 1. Since the ball D only gravitates on the *inclined plane*, with its relative gravity, the weight L, applied in a direction parallel to the length of the *plane*, will retain or suspend it, provided its weight be to that of the ball, as the altitude of the *plane* BA is to its length AC.

2. If the length of the *plane* CA be taken for the whole sine, or radius, AB will be the sine of the angle of inclination ACB. The absolute gravity of the body, therefore, is to its respective gravity applied to the *inclined plane*; and therefore, also the weight D to the weight L acting according to the direction DA, which sustains it, as the whole sine is to the sine of the angle of inclination.

3. Hence the respective gravities of the same body on different *inclined planes*, are to each other as the sines of the angle of inclination.

4. The greater therefore the respective gravity is, the greater is the angle of inclination.

5. As, therefore, in a vertical *plane*, where the inclination is greatest, viz. perpendicular; the respective gravity degenerates into absolute; so in a horizontal *plane*, where there is no inclination, the respective gravity vanishes: and hence it appears, that the inclination of the *plane* may be so small, that the greatest weight may be sustained on it by the smallest power.

II. To find the sine of the angle of inclination of a *plane*, on which a given power will be able to sustain a given weight. Say, as the weight it to the given power, so is the whole sine to the sine of the angle of inclination of the *plane*. Thus, suppose a weight of 1000 lb to be sustained by a power of 50, the angle of inclination will be found 3° 35′.

III. If the weight L descend according to the perpendicular direction AB, and raise up the weight D in a direction parallel to the *inclined plane*, the height of the ascent of D will be to that of the descent of L, as the sine of the angle of inclination C to the whole sine.

Hence, 1. The height of the ascent CD of the weight L, is to the height of ascent DH of the weight D, reciprocally as the weight D to the equivalent weight L.

2. Since then CD × L = DH × D, and the actions of the equiponderating bodies D and L are equal; the moments of the weights D and L are in a ratio compounded of their masses, and the altitudes through which they ascend or descend in a *plane*, either inclined or perpendicular.

3. The powers that raise weights through altitudes reciprocally proportional to them, are equal. This Des Cartes assumes as a principle whereby to demonstrate the power of machines.

Hence we see why a loaded waggon is drawn with more difficulty up an inclined than on an horizontal *plane*; as being pressed with a part of the weight which is to the whole weight in a ratio of the altitude of the plane, to its length.

IV. Weights E and F, *fig.* 92. equiponderating upon *inclined planes* A C and C B of the ſame height C D, are to each other as the lengths of the *planes* A C and C B.

S. Stevinus gives a very pretty demonſtration of this theorem, which, for its cafineſs and ingenuity, we ſhall here add. Put a chain, whoſe parts do all exactly weigh in proportion to their length, over a triangle, G I H, *fig.* 93; it is evident the parts G K and K H do balance each other. If then I H did not balance G I, the preponderating part would prevail; and there would ariſe a perpetual motion of the chain about G I H: but this being abſurd, it follows that the parts of the chain I H and G I, and conſequently all other bodies which are as the lengths of the *planes* I H and I G, will balance each other.

V. A heavy body deſcends on an *inclined plane*, with a motion uniformly accelerated.

Hence, 1. The ſpaces of deſcent are in a duplicate ratio of the times, and likewiſe of the velocities; and therefore in equal times they increaſe according to the unequal numbers, 1, 3, 5, 7, 9, &c.

2. The ſpace paſſed over by a heavy body deſcending on an *inclined plane* is ſubduple of that which it would paſs over in the ſame time, with the velocity it has acquired at the end of its fall.

3. Heavy bodies, therefore, deſcend by the ſame laws on *inclined planes*, as in perpendicular *planes*. Hence it was, that Galileo, to find the laws of perpendicular deſcent, made his experiments on *inclined planes*, becauſe the motions are ſlower in the latter than the former; as in the following theorem:

VI. The velocity of a heavy body deſcending on an *inclined plane*, at the end of any given time, is to the velocity which it would acquire in falling perpendicularly in the ſame time, as the height of the *inclined plane* is to its length.

VII. The ſpace paſſed over by a heavy body on an *inclined plane* A D (*fig.* 94.) is to the ſpace A B, it would paſs over in the ſame time in a perpendicular *plane*, as its velocity on the *inclined plane* is to its velocity in the perpendicular deſcent, at the end of any given time.

Hence, 1. The ſpace paſſed over on the *inclined plane* is to the ſpace it would deſcend in the ſame time in the perpendicular *plane*, as the altitude of the *plane* A B to its length A C; and therefore as the ſine of the angle of inclination C, to the whole ſine.

2. If then, from the right angle B, a perpendicular be let fall to A C; A C : A B :: A B : A D. So that in the ſame time wherein the body would fall perpendicularly from A to B; in an *inclined plane* it will deſcend from A to D.

3. The ſpace, therefore, of perpendicular deſcent being given in the altitude of the *plane* A B; by letting fall a perpendicular from B to A C, we have the ſpace A D to be paſſed over in the ſame time on the *inclined plane*.

4. In like manner, the ſpace A D, paſſed over on the *inclined plane*, being given, we have the ſpace A B, through which it would deſcend perpendicularly in the ſame time, by raiſing a perpendicular at D meeting the altitude of the *plane* in B.

5. Hence in the circle C D E F, *fig.* 95. the body will deſcend through all the *planes* A D, A E, A F, A C, in the ſame time; viz. in that time wherein it would fall through the diameter A B, ſuppoſing that perpendicular to the horizontal *plane* L M: becauſe all the angles D, E, F, C, in the ſemicircle, are right angles.

VIII. The ſpace A D, (*fig.* 94.) paſſed over an *inclined plane* A C being given, to determine the ſpace which would be paſſed over in any other *inclined plane* in the ſame time.

From the point D erect a perpendicular D B, meeting the altitude A B in B; then will A B be the ſpace through which the body would fall perpendicularly in that time. Wherefore if from B a perpendicular B E be let fall to the *plane* A F; A E will be the ſpace in the *inclined plane* which the body will paſs over, in the ſame time wherein it falls perpendicularly from A to B; and conſequently A D will be the ſpace in the other *inclined plane* A C, which it paſſes through in the ſame time.

Hence, ſince A B is to A D as the whole ſine to the ſine of the angle of inclination C; and A B is to A E as the whole ſine to the ſine of the angle of inclination F; the ſpaces A D and A E, which the body will paſs over in the ſame time on different *inclined planes*, are as the ſines of the angles of inclination, C and F, and reciprocally as the reſpective gravities on the ſame *planes*. And conſequently, they are alſo reciprocally as the lengths of *planes* equally high, A C and A F. Whence the problem may be reſolved various ways by calculation.

IX. The velocities acquired in the ſame time on different *inclined planes*, are as the ſpaces paſſed over in the ſame time.

For A D, A B, and A E, are the ſpaces paſſed over in the ſame time; and ſince A B : A C :: the velocity acquired in paſſing over A D to the velocity acquired in it, paſſing over A B; and A B : A F :: the velocity acquired in paſſing over A E to the velocity acquired in paſſing over A B; A B : A C :: A D : A B; and A B : A F :: A E : A B; the velocity acquired in paſſing over A D is to the velocity acquired in A B :: A D : A B, and the velocity acquired through A B to the velocity through A B :: A E : A B; therefore the velocities acquired in the ſame time in paſſing over A D and A E, will be as the ſpaces of A D and A E paſſed through in the ſame time.

Hence alſo, they are as the ſines of the angles of inclination C and F; reciprocally as the reſpective gravities on the ſame *planes*; and reciprocally as the lengths of equally high *planes* A C and A F.

X. A body deſcending on an *inclined plane* A C, when it arrives at the horizontal line C B, has acquired the ſame velocity which it would have acquired in a perpendicular deſcent A B, to the ſame horizontal line C B.

For A D is the ſpace paſſed over in the ſame time with A B; and, therefore, the celerity acquired in paſſing through A B is to that acquired through A D as A C to A B: but the celerity through A C is to that acquired through A D :: $\sqrt{AC} : \sqrt{AD}$, and, ſince A C : A B :: A B : A D, A C : A D :: A C : A B², and $\sqrt{AC} : \sqrt{AD}$ :: A C : A B: conſequently the celerity acquired through A C is to that acquired through A D as A C is to A B: therefore the celerity acquired through A C is equal to that acquired through A B.

Hence, 1. A heavy body deſcending through different *inclined planes*, A C, A G, A F, hath acquired the ſame velocity when it arrives at the ſame horizontal line B F. Hence alſo, 2. A body, continuing its deſcent through ſeveral contiguous *inclined planes*, acquires the ſame velocity which it would acquire in deſcending perpendicularly to the ſame horizontal *plane*.

XI. The time of deſcent along an *inclined plane* A C, is to the time of perpendicular deſcent through A B, as the length of the *plane* A C, to its altitude A B: but the times of deſcent through different *inclined planes* equally high, A C and A G, are as the lengths of the *planes*.

For the time through A C is equal to the time in which A C would be deſcribed uniformly with half the celerity acquired in C; and the time through A B is equal to that in which A B would be deſcribed uniformly with half the celerity acquired in B; but theſe celerities are equal; conſequently the times are as A C and A B. In the ſame manner it might be ſhewn, that the times of deſcent through A C and A G are as A C and A G.

XII. If the diameter of a circle A B (*fig.* 95.) be perpendicular to the horizontal line L M; a body will deſcend from any point of the periphery D, E, or C, to B, along an *inclined plane* D B, E B, and C B, in the ſame time wherein it will deſcend through the diameter A B.

For, letting fall the perpendicular C G, the time in which G B is deſcribed is to the time in which B C is deſcribed as B G : B C: but the time in which B C is deſcribed is to the time in which A B is deſcribed, in the ſubduplicate ratio of B G to A B; i. e. becauſe B G : B C :: B C : A B, in the ratio of B G to B C; conſequently, the time of deſcent through G B has the ſame ratio to the time of deſcent through B C and the diameter A B: therefore the time in which B C is deſcribed is equal to the time in which A B is deſcribed, &c. Hence,

XIII. The deſcents of bodies through a ſemicycloid D E F (*fig.* 96.) and through any arc thereof D G, are always iſochronal, or performed in the ſame time; on which principle is founded the doctrine of pendulums vibrating in a cycloid. See CYCLOID, and PENDULUM.

PLANES, *laws of deſcent of bodies on inclined.* I. If a body aſcend in a medium void of reſiſtance, in any direction, whether perpendicular, or along an *inclined plane*; its motion will be uniformly retarded.

Hence, 1. A body aſcending either perpendicularly or obliquely, in ſuch a medium, paſſes over a ſpace which is ſubduple of that it would paſs over in the ſame time in an *horizontal plane*, with an uniform celerity equal to that it has at the beginning of its motion.

2. Such ſpaces, therefore, performed in equal times, decreaſe in a retrograde order, as the uneven numbers 7, 5, 3, 1: and therefore the aſcent is ſo much impeded; and conſequently, when the impreſſed force is exhauſted, the body will deſcend again by the force of gravity.

3. They are, therefore, inverſely as the ſpaces deſcribed in the ſame times by a body deſcending through the ſame altitude. For, ſuppoſe the time divided into four parts; in the firſt moment, the body A deſcends through the ſpace 1, and B aſcends through 7 in the ſecond, A deſcends through 3, B aſcends through 5, &c.

4. Hence

4. Hence a body, rising with an impreſſed force, aſcends to that altitude, from which it muſt fall to acquire that velocity in falling wherewith it aſcended.

5. Hence, by falling, it acquires a force to riſe again to the height from whence it fell.

II. The time wherein a body aſcends to a given altitude, being given; to determine the ſpace paſſed over each moment.

Suppoſe the ſame body to deſcend from the ſame altitude in the ſame time; and find the ſpaces paſſed over each moment.

Theſe, taken inverſely, are the ſame with the ſpaces of aſcent required.

Suppoſe, v. gr. a body projected perpendicularly, to aſcend through a ſpace of 240 feet in four ſeconds; and the ſpaces of aſcent performed in the ſeveral times required; if now the body had deſcended, the deſcent in the firſt minute had been 15 feet, in the ſecond 45, in the third 75, in the fourth 105, &c. The deſcent therefore will be in the firſt moment 105, in the ſecond 75, &c.

III. If a body deſcend either perpendicularly through AD (*fig.* 96.) or in any other ſurface FED, and with the velocity it has there acquired, again aſcend along another ſurface DC, at points equally high, e. gr. at G, H, and Q, it will have the ſame force, and the ſame velocity.

Hence, if a body deſcend along any ſurface, FED, and again aſcend along another ſimilar and equal ſurface DGC, it is in the ſame as if it paſſed over the ſeveral parts of the ſame line twice.

Whence, the times of aſcent and deſcent through equal ſpaces are equal.

On this principle are founded the conſtruction and uſe of pendulums.

PLANE *of gravity*, or *gravitation*, is a plane ſuppoſed to paſs through the centre of gravity of the body, and in the direction of its tendency; that is, perpendicular to the horizon.

PLANE *of reflexion*, in *Catoptrics*, is a plane which paſſes through the point of reflexion; and is perpendicular to the plane of the glaſs, or reflecting body.

PLANE *of refraction* is a plane drawn through the incident and refracted ray.

PLANE, *perſpective*, is a plain pellucid ſurface, ordinarily perpendicular to the horizon, and placed between the ſpectator's eye and the object he views; through which the optic rays, emitted from the ſeveral points of the object, are ſuppoſed to paſs to the eye, and in their paſſage to leave marks that repreſent them on the ſaid plane.

Such is the *plane* HI (*Tab. Perſpect. fig.* 3). Some call it the *table*, or *picture*, becauſe the draught, or perſpective, of the object, is ſuppoſed to be thereon; others, the *ſection*, from its cutting the viſual rays; and others, the *glaſs*, from its ſuppoſed tranſparency. See PERSPECTIVE.

PLANE, *geometrical*, in *Perſpective*, is a plane parallel to the horizon, whereon the object to be delineated is ſuppoſed to be placed.

Such is the *plane* LM (*Tab. Perſpect. fig.* 3.) This *plane* is uſually at right angles with the *perſpective plane*. See PERSPECTIVE.

PLANE, *horizontal*, in *Perſpective*, is a plane paſſing through the ſpectator's eye, parallel to the horizon, cutting the perſpective *plane* when it is perpendicular to the geometrical one, at right angles.

PLANE, *vertical*, in *Perſpective*, a *plane* paſſing through the ſpectator's eye, perpendicular to the geometrical *plane*, and uſually at right angles to the perſpective *plane*. See PERSPECTIVE.

PLANE, *objective*, in *Perſpective*, is any *plane* ſituate in the horizontal *plane*, whoſe repreſentation in perſpective is required.

PLANE *of the horopter*, in *Optics*, is a *plane* that paſſes through the horopter AB (*Tab.* II. *Optics, fig.* 31) and is perpendicular to a *plane* paſſing through the two optic axes IC and CH. See HOROPTER.

PLANE *of the projection*, in the *Stereographic Projection of the Sphere*, is the ſame with the *perſpective plane*; which ſee.

PLANE *of a dial*, or *Dial*-PLANE, the ſurface whereon a dial is drawn. See DIAL.

We have *horizontal*, *vertical*, *inclining*, *declining*, *reclining*, *declinating*, *direct*, *oblique*, &c. *dial-planes*. See DECLINER, RECLINER, DIRECT, &c.

PLANE, *declination and inclination of a*. See DECLINATION and INCLINATION.

For the method of finding both, ſee DECLINATOR.

PLANE *glaſs*, *mirror*, *figure*, *number*, *problem*, &c. See PLAIN *glaſs*, *mirror*, *number*, *figure*, *problem*, &c.

PLANE, in *Joinery*, &c. denotes an edged inſtrument, uſed to pare or ſhave woods ſmooth, even, &c.

It conſiſts of a piece of wood very ſmooth at the bottom, ſerving as a ſtock, or ſhaft; in the middle whereof is an aperture, through which paſſes a ſteel edge, or chiſel, obliquely placed, and very ſharp, which takes off the inequalities of the wood it is ſlid along.

The *plane* acquires various names according to its various forms, ſizes, and uſes; as the

Jack plane, which is about eighteen inches long, and is that commonly firſt uſed; the edge of its iron is not ground ſtrait, but riſes with a convex arch in the middle, to bear being ſet the ranker; its uſe being to take off the greater irregularities of the ſtuff, and to prepare it for the

Long plane, which is about two feet in length, and ſmooths the work after the rough ſtuff is taken off by the former. This prepares the work for the *jointer*, if for the edges of a board; or for the

Smoothing-plane, which is ſhort and ſmall, being about ſix or ſeven inches in length, its iron fine; it takes off the great irregularities left by the *fore-plane*.

Jointer is the longeſt of all, being about ſix inches larger than the *long plane*; its edge very fine, not ſtanding out above a hair's breadth; it comes after the *ſmoothing-plane*, and is chiefly intended to ſhoot the edge of a board perfectly ſtraight for joining ſmooth tables, &c.

Rabbet-plane is uſed to cut the upper edge of a board, ſtraight or ſquare, down into the ſtuff, ſo as the edge of another, cut after the ſame manner, may join with it on the ſquare; it is alſo uſed to ſtrike faſeras in mouldings. Its iron is full as broad as its ſtock, that the angle may cut ſtraight; and it delivers its ſhavings at the ſides, not, like the others, at the top.

The *plough*, a narrow *rabbet-plane*, with the addition of two ſtaves, whereon are ſhoulders, and on the ſhoulders a fence. Its uſe is to plow a narrow ſquare groove on the edge of a board, &c.

Moulding-planes, called alſo *forſe-planes*. Of theſe there are various kinds, accommodated to the various forms and profiles of the mouldings.

Such are the *round-plane*, the *hollow*, the *O G*, the *ſnipe-bill*, &c. which are all of ſeveral ſizes, from half an inch to an inch and a half.

To uſe the *moulding-planes* on ſoft wood, as deal, pear-tree, &c. they ſet the iron to an angle of 45°, with the baſe or ſole of the *plane*. On hard wood, e. gr. ebony, box, &c. they ſet to an angle of 80°; ſometimes quite upright. To work on hard wood, the edge or baſil is ground to an angle of 18 or 20°; on ſoft wood to an angle of about 12°. For the more acute the baſil, the ſmoother the iron cuts; but the more obtuſe, the ſtronger. A method has been uſed of forming mouldings in marble with the *plane*.

PLANE, among *Fowlers*. To *plane*, is to fly or hover, as a kite or other bird does, without moving its wings.

PLANE-*tree*, *platanus*, in *Botany*, a genus of the *monœcia polyandria* claſs. Its characters are theſe: it hath male and female flowers growing ſeparate on the ſame tree; the male flowers are collected in a round ball; they have no petals, but have oblong coloured ſtamina, which are terminated by four-cornered ſummits; the female flowers have ſmall leafy empalements, and ſeveral ſmall concave petals, with ſeveral awl-ſhaped germina ſitting upon the ſtyles, crowned by recurved ſtigmas; theſe are collected in large balls; the germina afterward turn to roundiſh ſeeds ſitting upon the briſtly ſtyle, and ſurrounded with downy hairs. There are two ſpecies.

It is generally ſuppoſed, that the introduction of this tree into England is owing to the great lord-chancellor Bacon, who planted a noble parcel of them at Verulam, which were very flouriſhing ſome years ſince, but have lately been deſtroyed.

Notwithſtanding the *plane-tree* is backward in coming out in the ſpring, and the leaves decay ſoon in autumn, yet for the goodly appearance and great magnitude to which it will grow, it deſerves a place in large plantations, or ſhady receſſes near habitations, eſpecially if the plantation be deſigned on a moiſt ſoil, or near rivulets of water; in which places this tree will arrive to a prodigious ſize.

They are all propagated very eaſy by layers; every twig of them will take root, if they are but covered with earth; theſe layers will be well rooted in one year, when they ſhould be cut off from the old trees or ſtools, and planted in a nurſery, where they may remain two or three years to get ſtrength, and then be tranſplanted where they are to ſtand; for the younger theſe trees are planted, the better they will thrive. Miller.

PLANE-*tree*, *baſtard*, or *falſe*. See MAPLE.

PLANET, *planeta*, πλανήτης, *wanderer*; in oppoſition to a *ſtar* which remains fixed, in *Aſtronomy*, a celeſtial body, revolving round the ſun as a centre, and continually changing its poſition with reſpect to the other ſtars.

The *planets* are uſually diſtinguiſhed into *primary* and *ſecondary*.

PLANETS, *primary*, called also simply, and by way of eminence, *planets*, are those which move round the sun as their proper centre. Such are Saturn, Jupiter, Mars, the Earth, Venus, and Mercury.

PLANETS, *secondary*, are such as move round some *primary planet*, as their respective centre, in the same manner as the *primary planets* do round the sun. Saturn, Jupiter, and the Earth, are each attended with *secondary planets*; Jupiter with four, and Saturn with five, called the SATELLITES of those two *planets*.

The earth has one *secondary planet*, called the *moon*.

The motion of the primary *planets* is very simple and uniform, as being compounded only of a projectile motion, forward in a right line, which is a tangent to the orbit; and a gravitation towards the sun at the centre. See GRAVITY. Add, that being at such vast distances from each other, the effects of their mutual gravitation towards one another are in a considerable degree, though not altogether, insensible; for the action of Jupiter on Saturn, e. gr. is found to be $\frac{1}{1067}$ of the action of the sun upon Saturn, by comparing the matter of Jupiter with that of the sun, and the square of the distance of the sun from Saturn, with the square of the distance of Jupiter from Saturn; so that the elliptic orbit of Saturn will be found to be more just, if we suppose its focus not to be in the centre of the sun, but in the centre of gravity of the sun and Jupiter, or rather in the centre of gravity of the sun, and of all the *planets* below Saturn. In the same manner, the elliptic orbit of any other *planet* will be found more accurate, by supposing its focus to be to the centre of gravity of the sun, and of all the *planets* that are below it. But the matter is far otherwise, in respect of the *secondary planets*; for every one of these, though it chiefly gravitate towards its respective primary one, as towards its centre, yet at equal distances from the sun, it is also attracted towards him with an equally accelerated gravity, as the primary one is towards him; but with greater distance with less, and at a nearer distance with greater: from which double tendency towards the sun, and towards their own primary *planets*, the motion of the satellites, or *secondary planets*, comes to be very much compounded, and affected with many inequalities: as, for instance,

1. The satellite shall be continually accelerated in its motion, from the time of its quadrature with the sun to the next following conjunction or opposition; but contrariwise from the syzygies to the quadratures, it shall be retarded: and therefore it will always move swifter in or near the syzygies, and slower near the quadratures. From whence will follow that,

2. The orbits of these *secondary planets* will be of a figure more circular in the quadratures than in the syzygies, where the swiftness of the motion will make the figure of the orbit more rectilinear, and therefore the satellite will run farther from its primary planet at the quadratures than at the syzygies; so that the orbit will be a little elliptical, having the primary *planet* for its centre, and the longer diameter will coincide with the line of the quadratures, and the shorter with that of the syzygies. Which irregularities will arise, if the sun's power of disturbing the motion of the satellite be excluded, and the orbit be concentric with that of the primary *planets*: for if the orbit be eccentrical, it may happen that the satellite shall be farther off from the primary one in the syzygies, and so move slower than it does at the quadratures; and when this is the case, that the satellite's orbit is not a circle concentric to the primary orbit, but an ellipsis, in one of whose foci is the primary *planet* is placed, then the motion of the satellite will be so disturbed by the *sun*, that, as it proceeds in its orbit, the apsides of the orbit will be moved sometimes *in consequentia*, and sometimes *in antecedentia* (wherein the nodes and apsides of the primary *planets* are at rest).

3. When the plane of the satellite's orbit is inclined to the plane of the primary orbit, the line of the nodes of the *secondary* orbit will be moved *in antecedentia*, with an angular motion, and an unequal velocity; for it will recede most swiftly when the nodes are in quadrature to the sun; after which, it will move slower; and at the time of the nodes being in the syzygies, it will be perfectly at rest.

4. The inclination also of the plane of the *secondary* orbit, to the primary one, will be continually varying, and will be greatest when the nodes are in the syzygies with the sun, and less, *ceteris paribus*, when they are in the quadratures; and from the time of the nodes being in the syzygies, to the quadratures, it will be always decreasing, and from the time of their being in the quadratures to the syzygies, it will be always increasing: and all these irregularities, whether in any eccentric or concentric orbit, will always be something greater, when the satellite is in conjunction with the sun, than when he is in opposition to him. See MOON.

The *primary planets* are in number six, which are again distinguished into the *superior* and *inferior*.

PLANETS, *superior*, are those farther from the sun than our earth is. Such are Mars, Jupiter, and Saturn.

PLANETS, *inferior*, are those nearer the sun than our earth, and situate between the earth and sun. Such are Venus and Mercury. See the order, position, &c. of the *planets*, under *Copernican* SYSTEM.

The *planets* are represented by the same characters as the chemists use to represent their metals by, on account of some supposed analogy between these celestial and subterraneous bodies.

Saturn is represented by the character ♄. This *planet*, on account of its great distance, appears to the eye with a feeble light. It performs its revolutions round the sun in about thirty years.

Jupiter, marked ♃, is a bright refulgent star, finishing its course round the sun in about twelve years.

Mars, characterized ♂, is a ruddy fiery-coloured *planet*, finishing its course in about two years.

Venus, ♀, is the brightest of all the *planets*, constantly attending the sun, and never distant from him above 48 degrees. It finishes its course in about seven months.

When it goes before the sun, it is called PHOSPHORUS and *Lucifer*; and when it follows him, HESPERUS.

Mercury, ☿, a little bright *planet*, the sun's constant companion, from whose side it never departs above 28°, and by that means is usually hid in his splendor. It performs its course in about three months.

To which we now add Tellus, the earth, marked ⊕, performing its course about the sun, between Mars and Venus, in the space of a year.

From these definitions, a person may easily distinguish all the *planets*. For if after sun-set he sees a *planet* nearer the east than the west, he may conclude it is neither Mercury nor Venus; and may determine whether it is Saturn, Jupiter, or Mars, by the colour and light; by which also he may distinguish between Mercury and Venus.

PLANETS, *nature of*. From the several phases and appearances of the *planets*, they are found to be all like the moon, which we have shewn to be like our earth; whence it follows, that the *planets* are also dark, opake, spherical, &c. bodies, like our earth.

This may be shewn almost to a demonstration. 1. Venus observed with a telescope, is rarely found full, but with variable phases, like those of the moon; her illuminated part still turned towards the sun, viz. towards the east when she is the morning-star, and towards the west when the evening-star. And the like phases are observed in Mercury and Mars.

2. Gassendus first, and after him others, have observed Mercury on the face of the sun, across which he appeared to pass like a black round spot. Hevelius, in 1639, also observed Venus in the sun; where she made the same appearance. See PARALLAX and TRANSIT.

3. De la Hire, in 1700, with a telescope of fifteen feet, discovered mountains in Venus, larger than those of the moon.

4. Cassini observed two spots in Venus; four in Mars, likewise observed by Campani; and several, at several times, in Jupiter; and from his observations of these spots, he found that they had a rotation round their axes: he even determined the velocity of that motion, or the period wherein it was effected; v. gr. that of Jupiter, 9 hours 56′; that of Mars, 24 hours 40′; and that of Venus, 24 hours; and since the sun, moon, Jupiter, Mars, Venus, and the earth, are found to revolve on their axes, i. e. to have a diurnal rotation, no doubt Mercury and Saturn have the same; though the great nearness of the former to the sun, and the great distance of the latter, prevent any spots from being observed on them, whence that rotation might be demonstrated.

5. In Jupiter are observed two swathes, or belts, different from the rest of his disk, and moveable; they are sometimes found in one part, sometimes in another; and are sometimes broader, sometimes narrower.

6. In 1609 were first observed the little stars, or moons, moving about Jupiter, by Sim. Marius; and in 1610 the same were observed by Galileo: these are now frequently observed to disappear in a clear sky, when Jupiter happens to be diametrically interposed between them and the sun. Whence it appears they are void of light, at such time when the sun's rays, intercepted by Jupiter, cannot be propagated to them in right lines; and hence also that, like the moon, they are opake bodies illuminated by the sun; and hence again, since Jupiter does not illuminate his satellites when placed behind him, he himself, in that part turned from the sun, may be argued to be void of light.

7. When Jupiter's moons are diametrically interposed between Jupiter and the sun, there is seen a round spot on Jupiter's disk, which is sometimes larger than the satellite

tellite itſelf. Whence it appears, that the ſatellites are opake bodies, illuminated by the ſun; that they project a ſhadow from the ſun; and that the round ſpots, ſeen in Jupiter, are the ſhadows of the ſatellites.

Whence, alſo, the interſection of that ſhadow being found to be a circle, the ſhadow muſt be conical; and therefore the figure of the ſatellites, at leaſt as to ſenſe, is ſpherical.

3. The earth being between Jupiter and the ſun; if, at the ſame time, any of the ſatellites happen to be between Jupiter and the ſun, it is loſt in Jupiter's light; though ſometimes appearing like a black ſpot. This phenomenon has been frequently obſerved by Caſſini and Maraldi, who have likewiſe noted very conſiderable alterations in the apparent magnitudes of the ſatellites; for which no reaſon could be given from the diſtance of Jupiter, the ſun, or the earth: e. gr. that the fourth, which is uſually ſeen the ſmalleſt, is ſometimes the largeſt; and the third, which is uſually the largeſt, appears ſometimes the ſmalleſt. Hence, as the ſatellites are illuminated by the ſun, even then when immerged in Jupiter's light, yet do appear obſcure, there muſt be ſome alteration in their atmoſpheres, to prevent the ſun's rays being equally reflected from every part of their ſurface; which muſt likewiſe be the cauſe why their ſhadow is ſometimes larger than themſelves. Now, to ſum up the evidence: 1. Since in Venus, Mercury, and Mars, only that part of the diſk illuminated by the ſun, is found to ſhine; and, again, Venus, and Mercury, when between the earth and the ſun, appear like dark ſpots or maculæ, on the ſun's diſk, it is evident, that Mars, Jupiter, and Mercury, are opake bodies, illuminated with the borrowed light of the ſun. And the ſame appears of Jupiter, from its being void of light in that part to which the ſhadow of the ſatellites reaches, as well as in that part turned from the ſun; and that his ſatellites are opake, and reflect the ſun's light, is alſo abundantly ſhewn. Wherefore, ſince Saturn, with his ring and ſatellites, do only yield a faint light, fainter conſiderably than that of the fixed ſtars, though theſe be vaſtly more remote, and than that of the reſt of the *planets*, it is paſt doubt, that he too, with his attendants, are opake bodies.

2. Since the ſun's light is not tranſmitted through Mercury and Venus, when placed againſt him, it is plain they are denſe opake bodies; which is likewiſe evident of Jupiter, from his hiding the ſatellites in his ſhadow; and therefore, by analogy, the ſame may be concluded of Saturn.

3. From the variable ſpots in Venus, Mars, and Jupiter, ſome have concluded that theſe *planets* have a changeable atmoſphere; which changeable atmoſphere may, by a like argument, be inferred of the ſatellites of Jupiter; and therefore, by ſimilitude, the ſame may be concluded of the other *planets*. But we want a ſufficient number of obſervations to eſtabliſh this fact: there is reaſon, on the contrary, to apprehend, that ſome, at leaſt, of the *planets* have no atmoſphere. See MOON.

4. In like manner, from the mountains obſerved in Venus, the ſame may be ſuppoſed in the other *planets*.

5. Since then Saturn, Jupiter, the ſatellites of both, Mars, Venus, and Mercury, are opake bodies, ſhining with the ſun's borrowed light, and are furniſhed with mountains, and encompaſſed, as ſome have ſuppoſed, with a changeable atmoſphere, they have, of conſequence, waters, ſeas, &c. as well as dry land, and they are bodies, therefore, like the earth. Q. E. D.

And hence nothing hinders but that the *planets* may alſo be concluded to be inhabited. Huygens, in his Coſmotheoros, argues very plauſibly for the exiſtence of planetary inhabitants, from the ſimilitude of the *planets* with our earth: thoſe, like this, being opake, denſe, uneven, round, heavy, illuminated, and warmed by the ſun, having night and day, ſummer and winter, &c.

Wolfius deduces ſomething relating to this purpoſe from arguments of another kind. Thus, e. gr. it is fcarce to be doubted, that the inhabitants of Jupiter are much larger than thoſe of the earth, and, in effect, of the giant kind. For it is ſhewn in optics, that the pupil of the eye dilates in a ſtrong light, and contracts in a weak one: wherefore, ſince in Jupiter the ſun's meridian light is much feebler than on the earth, on account of Jupiter's greater diſtance from the ſun, the pupil will need to be much more dilatable in the inhabitants of Jupiter than in thoſe of the earth. But the pupil is obſerved to have a conſtant proportion to the ball of the eye, and the eye to the reſt of the body; ſo that in animals, the larger the pupil the larger the eye, and the larger the body.

To aſcertain the ſize of theſe Jovial inhabitants, it may be obſerved, that the diſtance of Jupiter from the ſun is to the earth's diſtance from the ſame, as 26 to 5; the intenſity of the ſun's light in Jupiter is to its intenſity on the earth, in a duplicate ratio of 5 to 26; but it is found by experience, that the pupil dilates in a ratio greater than that wherein the intenſity of light decreaſes; otherwiſe, a body at a great diſtance might be ſeen as clearly as a nearer: the diameter, therefore, of the pupil in its greateſt dilatation, in the earth, is to its diameter in the like ſtate in Jupiter, in a ratio greater than that of the duplicate of 5 to 26. If then we put it as 10 to 26, or as 5 to 13; ſince the ordinary ſtature of the inhabitants of the earth is computed at 5 Engliſh feet 4 inches and ½ (which Wolfius tells us was his own height), the ordinary ſtature of Jupiter's inhabitants will be found 14 feet ½, which is very nearly the ſize of the giant Og, mentioned by Moſes, whoſe iron bed was 9 cubits long, and its breadth 4. But arguments of this kind being more whimſical than ſolid, are needleſs, in order to juſtify the ſimilarity of the other *planets* to our earth, and a conjecture, that they are deſtined by the Creator for the ſame purpoſe.

PLANETS, *motion of the*. That the *planets* do all revolve round the ſun as their centre, and not round the earth, is evident from a thouſand phenomena. 1. The orbit wherein Venus, e. gr. moves, does certainly encompaſs the ſun; and therefore, in deſcribing that orbit, the *planet* muſt turn round the ſun.

That her orbit includes the ſun, appears hence, that ſhe is ſometimes above the ſun, ſometimes below it, ſometimes beyond it, and ſometimes on this ſide; all which are evident from the circumſtances of her phaſes.

That ſhe does not move round the earth, is no leſs apparent from her being ever obſerved in the ſame quarter with the ſun, never receding from him above 48°. She never therefore comes to be in oppoſition to the ſun; no, not to be in a quartile aſpect, or to have a quarter of the heavens between them; both which, like the earth, ſhe muſt frequently have, did ſhe attend and move round the earth.

2. That Mercury revolves round the ſun, appears in like manner from his phaſes, which reſemble thoſe of Venus and the moon; and from his neighbourhood to the ſun, from whom Mercury never recedes ſo far as Venus does.

3. That the orbit of Mars includes the ſun, is evident from that *planet*'s being found both in conjunction and oppoſition with the ſun; and in both caſes ſhining with a full face. Indeed, from the ſame circumſtances it appears, that the orbit of Mars encompaſſes the earth; but then it follows, likewiſe, from Mars's diameter appearing ſeven times as big when in oppoſition, as when in conjunction, that he is ſeven times nearer the earth in the former than the latter poſition. The earth, therefore, is far from being the centre of Mars's *motion*; but Mars is ever nearly at the ſame diſtance from the ſun. Again, Mars viewed from the earth moves very irregularly; is ſometimes ſeen to proceed ſlower, ſometimes faſter; ſometimes he ſtands ſtill, and ſometimes he goes backward (the reaſons whereof, ſee under the article OPTICAL *inequality*); but viewed from the ſun, he will ever appear to move with the ſame conſtant uniform tenor; whence it is evident, he reſpects the ſun, not the earth, as the centre of his *motion*.

4. The ſame appearances whence Mars is ſhewn to revolve round the ſun as a centre, are likewiſe obſerved in Jupiter and Saturn; whence the ſame concluſion may be made of them.

Laſtly, that the earth revolves round the ſun, as a centre, is evident from her place, which we have obſerved to be between the orbits of Mars and Venus; and from the phenomena of the ſuperior *planets* viewed from it. If the earth ſtood ſtill, we ſhould never ſee thoſe *planets* either ſtationary or retrograde: the earth therefore moves, but it is ſtill found between the orbits of Mars and Venus, which encompaſs the ſun; therefore the earth alſo encompaſſes the ſun.

To this aſtronomical demonſtration, may be added a phyſical demonſtration of the earth's motion from Sir Iſaac Newton. It appears from abundant obſervation, that either the earth turns round the ſun, or the ſun round the earth, ſo as to deſcribe equal areas in equal times; but he demonſtrates, that bodies revolving about one another according to ſuch law, do of neceſſity gravitate toward each other. Whence, if the ſun gravitate to the earth, action and reaction being ſtill equal, the earth will likewiſe gravitate toward the ſun. But he proves, farther, that two bodies gravitating towards each other, without directly approaching one another in right lines, muſt both of them turn round the common centre of gravity of both. The ſun and earth, therefore, do both revolve round one common centre; but the earth being but a point in compariſon of the ſun, the common centre of gravity of the two will be within the ſun's body, and not far from its centre. The earth, therefore, revolves round a point, within the body of the ſun, and therefore round the ſun. See the arguments for the earth's motion, under EARTH.

From the transit of Venus over the sun on the 6th of June, 1761, Mr. Ferguson has given the following account of the magnitudes, distances, revolutions, &c. of the sun and *planets*. See PARALLAX.

The sun's diameter is 890,000 Englifh miles, his fuperficial contens (or number of fquare miles contained in his furface) is 2,488,461,300,000, and his folid content, in cubic miles, is 369,121,768,400,000,000. He revolves round his axis in 25 days 6 hours, and his axis is inclined to the plane of the ecliptic at an angle of 8°.

Mercury's diameter is 3000 miles, its fuperficial content is 28,274,400 fquare miles, and its folid content is 14,137,200,000 cubic miles. Its diftance from the fun is 36,841,408 miles; it goes round the fun in 87 days 23 hours, moving at the rate of 109,699,$\frac{5}{8}$ miles per hour. The inclination of its orbit to the plane of the ecliptic is 6° 54'; the plane of its aphelion ♌ 13° 8', and the place of its afcending node ♈ 14° 43'.

Venus's diameter is 9330 miles, its fuperficial content is 273,472,824 fquare miles, and its folid content is 425,250,241,693 cubic miles. Its diftance from the fun is 68,891,486 miles; it goes round the fun in 224 days 17 hours, moving at the rate of 80,285,$\frac{2}{8}$ miles per hour; and round its own axis in 24 days 8 hours; its axis is inclined to the plane of its orbit at an angle of 75°; its orbit inclined to the ecliptic at an angle of 3° 20'; the place of its aphelion ♊ 4° 20'; and the place of its afcending node in 13° 59'.

The Earth's diameter is 7970 miles; its furface contains 199,537,259 fquare miles, and its folid content or bulk is 265,078,559,633 cubic miles. Its diftance from the fun is 95,173,000 miles; it goes round the fun in a year, moving at the rate of 68,243,$\frac{3}{8}$ miles per hour. Its axis is inclined to its orbit 23° 29'; and the place of its aphelion is ♑ 8° 1'.

Mars's diameter is 5400 miles; its fuperficial content is 91,608,456 fquare miles, and its folid content, in cubic miles, is 82,148,140,400. Its diftance from the fun is 145,014,148 miles; it goes round the fun in 1 year 321 days 17 hours, moving at the rate of 55,287 miles per hour. It revolves round its axis in 24 hours 40'; its orbit is inclined to the ecliptic at an angle of 1° 52'; the place of its aphelion is ♓ 0° 32', and of its afcending node ♉ 17° 17'.

Jupiter's diameter is 94000 miles; its fuperficial content is 27,759,077,600 fquare miles, and its folid content, in cubic miles, is 434,803,787,400,000. Its diftance from the fun is 494,990,976 miles; it goes round the fun in 11 years 314 days 18 hours, moving at the rate of 29,683,$\frac{3}{8}$ miles per hour. It revolves round its axis in 9 hours 56'; its orbit is inclined to the ecliptic at an angle of 1° 26'; the place of its aphelion is ♎ 9° 10', and of its afcending node ♋ 7° 20'.

Saturn's diameter is 78000 miles; its fuperficial content is 19,113,494,400 fquare miles; and its folid content, in cubic miles, is 248,475,427,200,000. Its diftance from the fun is 907,936,130 miles; it goes round the fun in 29 years 167 days 6 hours, moving at the rate of 22,101,$\frac{7}{8}$ miles per hour. His orbit is inclined to the ecliptic at an angle of 2° 30'; the place of its aphelion ♐ 25° 50', and of its afcending node ♋ 11° 13'.

The Sun is 539$\frac{1}{2}$ times as big as all the *planets* put together.

The Sun is 26,169,963 times as big as Mercury, 845,019 times as big as Venus, 1,392,500 times as big as the Earth, 4,477,011 times as big as Mars, 849 times as big as Jupiter, and 1,490 times as big as Saturn.

The Earth's bulk is to Mercury's bulk as 1 to 7,$\frac{1}{8}$, to Venus's bulk as 1 to 1,$\frac{1}{8}$, to Mars's bulk as 1 to 1,$\frac{1}{8}$, to Jupiter's bulk as 1 to 1640, and to Saturn's bulk as 1 to 937.

Supposing the light and heat received by the earth to be 1, thofe of Mercury will be 6$\frac{1}{2}$, of Venus 1$\frac{1}{2}$, of Mars $\frac{1}{3}$, of Jupiter $\frac{1}{27}$, of Saturn $\frac{1}{90}$.

If a body, projected from the fun, fhould continue to fly at the rate of 480 miles per hour (which is about the fwiftnefs of a cannon ball), it would reach the orbit of Mercury in 8 years 276 days; of Venus in 16 years 136 days; of the Earth in 22 years 226 days; of Mars in 34 years 169 days; of Jupiter in 117 years 234 days; and of Saturn in 215 years 287 days.

The Moon's diameter is 2180 miles; her bulk is in proportion to the Earth's bulk as 1 to 48,$\frac{1}{2}$; her diftance from the earth's centre is 240,000 miles, and a cannon ball would go from the earth's centre to the moon in 26 days 20 hours. She goes round her orbit in 27 days 7 hours 43 minutes, moving at the rate of 2209,$\frac{7}{8}$ miles per hour.

The quantities of matter in the Sun, Jupiter, Saturn, and the Earth, as determined by the Newtonian theory of gravity, are to each other as the numbers 1, $\frac{1}{1067}$, $\frac{1}{2855}$, and their denfities as the numbers 100, 94$\frac{1}{2}$, 67, and 400; and their attractive powers at their furfaces as the numbers 10000, 9425, 529, 435, refpectively.

Mr. Hutton, by very elaborate calculations, founded on the furvey and meafures taken at Schehallien, with a view to afcertain the ATTRACTION *of mountains*, has deduced the mean denfity of the earth, in comparifon with water, to be as 4$\frac{1}{2}$ to 1; and the relative denfities of the fun and *planets*, in refpect of water, admitting the denfities compared with each other to be as M. de la Lande has ftated them in his Aftronomy, will be as follow; viz. water 1, the fun 1,$\frac{1}{4}$, Mercury 9$\frac{1}{2}$, Venus 5$\frac{1}{4}$, the Earth 4$\frac{1}{2}$, Mars 3$\frac{1}{2}$, the Moon 3,$\frac{1}{4}$, Jupiter 1,$\frac{1}{2}$, and Saturn $\frac{1}{2}$. Phil. Tranf. vol. lxviii. part ii. art. 33.

For the diameters of the fun and *planets*, as feen from the earth, and the diameters of the *planets*, as feen from the fun, fee DIAMETER.

For the relative mean diftances of the *planets* from the fun, fee DISTANCE.

For the eccentricities of the *planets*, fee ECCENTRICITY.

The orbits of the *planets* are all ellipfes; one of whofe foci is in the fun. This Kepler firft found from Tycho's obfervations; before him, all aftronomers took the planetary orbits for eccentric circles.

The planes of thefe orbits do all interfect in the fun; and the line wherein the plane of each orbit cuts that of the earth, is called the *line of the nodes*; and the two points wherein the orbits themfelves touch that plane, *the nodes*.

The diftance between the centre of the fun, and the centre of each orbit, is called the ECCENTRICITY *of the planets*.

And the angle at which each plane cuts that of the ecliptic, is called *the inclination of the planes*.

To account for the *motion of the planets* about the fun, there needs nothing but to fuppofe an uniform projectile *motion*, in ftraight lines, at firft given them; and a power of attraction or gravitation, fuch as we obferve in all the great bodies in our fyftem. For a body A (*Tab. Aftron. fig.* 45) proceeding uniformly along the line AB, will, by the intervention of the attracting body C, be every moment diverted out of its rectilinear, and bent into a curvilinear path, according to the laws of central forces. If, then, the projectile *motion* be perpendicular to a line, CA, drawn from the attracting body C; and its velocity be fo proportioned to the force of attraction of A, as that the centripetal and centrifugal forces are equal, i. e. that the conatus to fall to the central body C, in a right line, AC; and that to proceed in the direction of the tangent, A B, balance each other; the body will revolve in a circular orbit, A, *b*, 7, 3, &c.

It is not improbable, that at the beginning this was the ftate of things; and that the velocities impreffed on the feveral *planets* were fo combined with their refpective maffes and diftances from the fun at which they were to roll, as that their momenta fhould counterbalance the fun's attractive force, and be precifely counterbalanced thereby; whence the primitive orbits muft have been perfect circles, from which they do not even now deviate very far. See ECCENTRICITY.

If the *planet's* projectile *motion* be not perfectly adjufted to the fun's attraction, the orbit defcribed will be an ellipfis. If it be too fwift, the orbit will be greater than a circle, and the nearer focus coincides with the central body; if too flow, the orbit will be lefs than a circle, and the farther focus coincide with the central body.

Indeed the form of the planetary orbits does not only depend on the adjuftment of the firft projectile velocity with the fun's attraction, but alfo on the direction wherein that motion was originally impreffed. If that direction were according to the tangent AB, as above fuppofed, and the central forces exactly balanced, the orbit would be circular; but if that direction were oblique, in any manner, whether afcending to or defcending from the fun, the orbit of the *planet*, notwithftanding any adjuftment of its velocity to the attraction, would be an ellipfis.

The *motions of the planets* in their ellipfic orbits are not equable, becaufe the fun is not in their centre, but their focus. Hence they move, fometimes fafter, and fometimes flower, as they are nearer or farther from the fun; but yet thefe irregularities are all certain, and follow according to an immutable law.

Thus, fuppofe the ellipfis BEP, &c. (*Tab. Aftron. fig.* 47.) the orbit of a *planet*, and the focus S, the fun's place; AP, the axis of the ellipfis, is called the *line of the apfides*; the point A, the *higher apfis* or *aphelion*; P, the *lower apfis* or *perihelion*; SC, the eccentricity; and ES, the mean diftance of the *planet* from the fun.

Now the *motion of the planet* in its perihelion, is fwifteft, and in its aphelion, floweft; at E the *motion* as well as the

the diſtance is mean, i. e. it is ſuch as would deſcribe the whole orbit in the ſame time it is really deſcribed in. The law whereby the *motion* is regulated in every point of the orbit, is, that a line, or radius, drawn from the centre of the ſun to the centre of the *planet*, and thus carried along with an angular *motion*, does always deſcribe an elliptic area proportional to the time. Suppoſe, e. gr. the *planet* in A, and thence in a certain time to proceed to B; the ſpace or area the radius SA deſcribes, is the triangle ASB: when, at length, the *planet* arrives at P, if from the centre of the ſun S there be drawn SD, in ſuch manner as that the elliptic area PSD is equal to that of ASB, the *planet* will here move through the arch PD, in the ſame time wherein it moved through the arch AB; which arcs are unequal, and nearly in a reciprocal proportion to their diſtance from the ſun. For from the equality of the areas it follows, that the arch PD muſt exceed AB as much as SA exceeds SP. This law was firſt demonſtrated by Kepler, from obſervation; and is ſince accounted for by Sir I. Newton from phyſical principles; and to this all aſtronomers now ſubſcribe, as of all others that which beſt ſolves the planetary phenomena.

Computation of a PLANET's *motion and place.* As to the periods and velocities of the *planets*, or the times wherein they perform their courſes, they are found to have a wonderful harmony with their diſtances from the ſun, and with one another. The nearer each *planet* is to the ſun, the quicker ſtill being its motion, and its period the ſhorter. The great law they here all immutably obſerve is, that the ſquares of their periodical times are as the cubes of their diſtances from the centres of their orbits. The knowledge of this law we alſo owe to the ſagacity of Kepler, who found it to obtain in all the primary *planets*; as aſtronomers have ſince found it alſo to do in the ſecondary ones.

Kepler deduced this law merely from obſervation, and compariſon of the ſeveral diſtances of the *planets* with their periods: the glory of inveſtigating it from phyſical principles is due to Sir Iſaac Newton, who has demonſtrated, that, in the preſent ſtate of things, ſuch a law was inevitable.

A *planet*'s motion, or diſtance from its apogee, is called the *mean anomaly* of the *planet*; and is meaſured by the arc or area it deſcribes in the time. When the *planet* arrives at the middle of its orbit, or the point G, the diſtance or time is called the *true anomaly*. When the *planet*'s motion is reckoned from the firſt point of Aries, it is called its *motion in longitude*; which is either mean, viz. ſuch as the *planet* would have, were it to move uniformly in a circle; or true, which is that wherewith the *planet* actually deſcribes its orbit, and meaſured by the arc of the ecliptic it deſcribes.

Hence may the *planet*'s place in its orbit for any given time after it has left the aphelion be found. For ſuppoſe the area of the ellipſis ſo divided by the line SG, that the whole elliptic area may have the ſame proportion to the area ASG as the whole periodical time wherein the *planet* deſcribes its orbit has to the time given: in this caſe G will be the *planet*'s place in its orbit.

PLANETS, *the phenomena of the inferior*, are their conjunctions, elongations, ſtations, retrogradations, phaſes, and eclipſes. See CONJUNCTION, ELONGATION, STATION, RETROGRADATION, &c.

PLANETS, *phenomena of the ſuperior*, are the ſame with thoſe of the inferior; with an additional one, viz. oppoſition.

PLANET, *the particular phenomena, circumſtances, &c. of each*, ſee under the name of the reſpective *planet*, &c. JUPITER, MARS, &c.

PLANETS, *configuration of the*. See CONFIGURATION.

PLANETS, *theories of the*. See THEORY.

PLANETARIUM, an aſtronomical machine, made to repreſent the motions of the planets, as they really are in nature, or at leaſt agreeably to the Copernican ſyſtem, and commonly called an ORRERY.

The moſt remarkable of theſe machines was that invented by Huygens, and deſcribed by him. See Deſcript. Automati Planetarii, ap. Huygen. Opuſcul. poſthum. tom. ii. p. 157, edit. Amſt. 1728.

In this *planetarium*, the five primary planets perform their revolutions about the ſun; and the moon performs her revolution about the earth, in the ſame time that theſe revolutions are really performed in the heavens. The orbits alſo of the moon and planets are repreſented with their true proportions, eccentricity, poſition, and declination, from the ecliptic or orbit of the earth; ſo that by this *planetarium* the ſituation of the planets, the conjunctions, oppoſitions, &c. may not only be known for the preſent time, but for any time paſt, or future, as in a perpetual ephemeris.

This machine is now preſerved among the curioſities of the univerſity of Leyden.

But the *planetariums* or orreries now moſt commonly uſed do not repreſent the true times of the celeſtial motions, but only their proportions; and are of uſe to beginners, to give them an idea of the planetary ſyſtem; as alſo, if conſtructed with ſufficient accuracy, to ſolve queſtions relating to the motions of the planets, and of the earth and moon, &c.

Theſe machines are made of various ſizes, ſome repreſenting more planets than others. However, theſe complex ones are far from being improvements upon the original *planetarium*, or orrery, which ſhewed only the motion of the moon round the earth, and of the earth and moon round the ſun. They give but very confuſed, and even falſe ideas of the diſtances and bigneſs of the planets; which muſt always be ſo whilſt the orbits of the moon, and other ſecondary planets, are fixed to the ſame machine, which contains the primary one. In the original one, every thing was well and properly executed; as the phenomena of day and night, and their gradual increaſe and decreaſe according to the ſeaſons; the places of the earth where the ſun is ſucceſſively vertical, and ſeems to deſcribe its parallels; the real annual motion of the earth, which gives the ſun an apparent annual motion; the rotation of the ſun about its axis; the periodical and ſynodical month; the ſolar and ſydereal days; the ſucceſſive illumination of all the parts of the moon, &c.

It is therefore proper to have a machine for repreſenting the general ſolar ſyſtem by itſelf; the ſun, moon, and earth, ought alſo to be ſhewn ſeparately; and the ſyſtem of any other primary planet; as Jupiter, for inſtance, with all its ſatellites, ſhould have a ſeparate machine ſo contrived, as to repreſent in true proportion their magnitudes, diſtances, and other phenomena.

Dr. Deſaguliers deſcribes a *planetarium* of his own contrivance, the frame of which, containing the clock-work, is made of ebony; its outſide is adorned with twelve pilaſters, between which are painted, on as many vertical planes, the twelve ſigns of the zodiac. The upper ſurface is flat, and made of poliſhed braſs; on the outward circumference of which are ſcrewed ſix braſs pillars, ſupporting a large flat ſilvered ring. On this ring, which repreſents the ecliptic, are drawn ſeveral circles; the three innermoſt being divided into twelve parts for the ſigns of the zodiac, and each of theſe into thirty degrees; and among thoſe degrees are graved in their proper places the nodes, aphelia, and greateſt north and ſouth latitudes of the planets. The next three circles have the months and days of the month, exactly correſponding to the ſun's place at noon each day throughout the year; and upon the braſs ſurface of the machine graduated are ſilver circles, which carry the planets, repreſented by ſilver balls, and raiſed upon arbors or ſtems to the height of the ecliptic.

Above the ecliptic ſtand ſome of the principal circles of the ſphere, according to their reſpective ſituation in the heavens, viz. the two colures, one half of the equinoctial circle, the tropic of Cancer, the arctic circle, &c. The whole machine is alſo ſo contrived, as to be ſet to any latitude, without injuring any of the inſide motions. Within the ecliptic ſtand the ſun and other planets; the ſun being in the centre of the whole ſyſtem, and the reſt repreſented agreeably to the above mentioned magnitudes and diſtances. When things are thus diſpoſed, by turning about the handle, or winch, of the *planetarium*, all the planets perform their revolutions round the ſun, according to their periodical times; and being furniſhed with indices of blued ſteel, theſe ſhew the longitudes of the planets, by pointing to the diviſions on the graduated ſilver circles, as they move round.

As the diſtances of the planets are in their true proportions to each other, ſo likewiſe are their magnitudes; but it cannot be expected, that the diameters of the planets ſhould be in proportion to the diameters of their orbits; for to effect this, the machine muſt either be made three thouſand times bigger than uſual, or the balls repreſenting the planets three thouſand times leſs than uſual; whereby they would all be rendered inviſible, excepting the ſun, and even it would be leſs than $\frac{1}{100}$th part of an inch in diameter. For the ſame reaſon it is found impracticable to repreſent the ſun by a ball, proportionally bigger than thoſe repreſenting the other planets.

Now as the orbit of the moon, as well as of the ſatellites of Jupiter and Saturn, bear no manner of proportion to the orbits of the primary planets, the diſproportion between theſe and their ſatellites muſt be ſtill greater. Hence appears the abſurdity of crowding them all into one machine, as is the caſe in the common orreries.

To give a right notion of the diſtances and magnitudes of the ſatellites with reſpect to their primary planets, it will be neceſſary to have a ſeparate machine for each ſyſtem; or, the ſame machine may be ſo contrived, as

to

to represent one system after another, by shifting and adjusting the magnitudes and distances of the balls. In this manner, the general solar system may be first exhibited; then that of the moon and earth round the sun; afterwards that of Jupiter and its satellites; and, lastly, that of Saturn and its satellites.

We have already taken notice of some of the phenomena explained by the general *planetarium*, as well as of that contrived to exhibit the revolution of the earth and moon round the sun. By these is likewise plainly shewn the causes of eclipses, as well as of the apparent stationary and retrograde motions of the planets.

By the *planetarium* adapted to the system of Jupiter, and its satellites, are exhibited the immersion or entrance of a satellite into the shadow of Jupiter; its emersion out of the shadow; when these are visible; when a satellite is hidden by the body of Jupiter before it comes into, or after it is gone out of the shadow; when a satellite may be seen to cross the body of Jupiter; when a satellite makes a solar eclipse in Jupiter; and when satellites eclipse one another. See Desaguliers's Exper. Phil. vol. i. p. 470, &c.

PLANETARY, something that relates to the *planets*.

In this sense we say *planetary* worlds, *planetary* inhabitants, &c. Huygens and Fontenelle bring several probable arguments for the reality of *planetary* worlds, and animals, plants, men, &c. The former in his *Kosmotheoros*, five de Terris Coelestibus; the latter in his Dialogues, Sur la Pluralité des Mondes.

PLANETARY *globe*. See GLOBE.

PLANETARY *system*, is the system or assemblage of the *planets*, primary and secondary, moving in their respective orbits round their common centre, the sun.

PLANETARY *hours*, in *Chronology*. See HOUR.

PLANETARY *days*. Among the ancients, the week was shared among the seven planets, each planet having its day. This we learn from Dion Cassius, and Plutarch, Synpos. lib. iv. q. 7. Herodotus adds, that they were the Egyptians who first discovered what god, that is, what planet, presides over each day; because among this people the planets were directors. And hence it is, that, in most European languages, the days of the week are still denominated from the planets; Sunday, Monday, &c.

PLANETARY *years*, the periods of time wherein the several planets make their revolutions round the sun, or earth.

As from the proper revolution of the sun, the solar year takes its original; so from the proper revolutions of the rest of the planets about the earth, so many sorts of years do arise; viz. the Saturnian year, which is defined by 29 Egyptian years, 174 hours 58 minutes, equivalent in a round number to 30 solar years. The Jovial year, containing 317 days 14 hours 59 minutes. The Martial year, containing 321 days 23 hours 31 minutes. For Venus and Mercury, as their years, when judged of with regard to the earth, are almost equal to the solar year; they are more usually estimated from the sun, the true centre of their motions: in which case, the former is equal to 224 days 16 hours 40 minutes; the latter to 87 days 23 hours 14 minutes.

PLANETARY *hours*, those wherein the *planetary* hours are inscribed.

PLANETARY *squares*, the squares of the seven numbers from 3 to 9, disposed magically.

Corn. Agrippa, in his famous book of magic, has given the construction of the seven *planetary* squares: M. Poignard, canon of Bruffels, in his Treatise of Sublime Squares, gives new, easy, and general methods, for making the seven *planetary* squares, and all others to infinity, by numbers in all sorts of progressions. See MAGIC *Square*.

PLANIFOLIOUS *flowers*. See FLOWER.

PLANIMETRY, *planimetria*, that part of geometry which considers lines and plain figures; without any consideration of heights or depths.

Planimetry is particularly restrained to the mensuration of planes or surfaces: in opposition to *stereometry*, or the mensuration of solids. See MEASURING and SURVEYING.

Planimetry, or the art of measuring the surfaces and planes of things, is performed with the squares of long measures, as square feet, square inches, square yards, square perches, &c. that is, by squares whose sides are an inch, a foot, a yard, a perch, &c. so that the area or content of any surface is said to be found, when we know how many such square inches, feet, yards, &c. it contains.

PLANISPHERE, a projection of the sphere, and the several circles thereof, on a plane; as upon paper, or the like.

In this sense, maps of the heavens and the earth, wherein are exhibited the meridians, and other circles of the sphere, are called *planispheres*.

PLANISPHERE is sometimes also considered as an astronomical instrument, used in observing the motions of the heavenly bodies; consisting of a projection of the celestial sphere upon a plane, representing the stars, constellations, &c. in their proper situations, distances, &c. Such is the ASTROLABE, which is a common name for all such projections.

In all *planispheres*, the eye is supposed to be a point viewing all the circles of the sphere, and referring them to a plane whereon the sphere is as it were flattened. This plane is called the *plane of the projection*.

A perspective plane is only a plane of projection placed between the eye and the object, so as to contain all the points which the several rays drawn from the object to the eye impress thereon. But in *planispheres* or astrolabes, the plane of the projection is placed beyond the object; which is the sphere. The plane of the projection is always some of the circles of the sphere.

Among the infinite number of *planispheres* which the different planes of projection, and the different positions of the eye, would furnish, there are two or three that have been preferred to the rest. Such are that of Ptolemy, where the plane of projection is parallel to the equator: that of Gemma Frisius, where the plane of projection is the colure, or solstitial meridian, and the eye the pole of the meridian: that of John de Royas, a Spaniard, whose plane of projection is a meridian, and the eye placed in the axis of that meridian, at an infinite distance. This last is called the ANALEMMA.

The common defect of all these projections is, that they distort and alter the figures of the constellations to as it is not easy to compare them with the heavens; and that the degrees in some places are so small, that they afford no room for operation.

All these faults M. de la Hire has provided against in a new projection, or *planisphere*; where it is proposed the eye shall be so placed, as that the divisions of the circles projected shall be sensibly equal in every part of the instrument. The plane of his projection is that of a meridian.

PLANISPHERE, *nautical*. See NAUTICAL.

PLANKING, in *Naval Architecture*, the art of covering and lining the sides of a ship with an assemblage of oak planks, which completes the process of ship-building, and is sometimes called by artificers laying on the skin.

PLANKS, in a *Ship*, are the timbers which go fore and aft on each side of the ship, whereon lie the beams of the first orlop.

PLANK, *garboard*, in a *Ship*. See GARBOARD.

PLANO-*concave glass*, or *lens*. See LENS.

PLANO-*convex glass*, or *lens*. See LENS.

PLANT, *planta*, an organical body, consisting of a root, and other parts; and producing usually leaves, a stem, branches, and flowers.

A *plant* may be defined in Boerhaave's manner to be an organical body composed of vessels and juices; to which body belong a root, or a part whereby it adheres to some other body, and particularly the earth, from which it derives the matter of its life and growth.

A *plant* is distinguished from a fossil by its being organical, and consisting of vessels and juices; and from an animal, by its adhering to another body, and deriving its nourishment therefrom.

That *plants* are organized bodies and endued with life is evident from many considerations: every body that has spontaneous motion must also have life; for proper and internal motion in every body depends on the spontaneous propulsion of fluids, and where this manifests itself, there is life. This kind of motion in *plants* appears in a variety of circumstances: thus herbs in green-houses or flores incline or turn towards the light. When shut up, if they find a hole in the wall, shutters, or frames, there they endeavour to penetrate. Several *plants* in the day-time turn their flowers towards the sun; most *plants* in a serene sky expand their flowers; but before rain, shut them up, or contract them at the approach of night. The flowers of many *plants* hang down in the night, as if the *plants* were asleep, lest rain or the moist air should injure the fertilizing dust. The trefoile, &c. shut up, or double their leaves before storms and tempests, but unfold them in a clear sky. The tamarind-tree is said by Alpinus and Acosta to enfold within its leaves the flowers or fruit every night, in order to guard them from cold or rain. Some of the sensitive *plants* and the wood-sorrel with pinnated leaves, upon being touched, roll up their leaves, and turn downwards or shrink, and after a little time expand them again, as if they had both life and sensation. And it farther appears, that motion is no less necessary to the vigour of *plants*, than exercise to the health and strength of animals. Thus *plants* in stoves and green-houses, though they have sufficient heat and nourishment, are slender, weak, and lose the colour of their leaves, and

learn

ſeem to languiſh for want of motion; and trees, ſurrounded with high walls or buildings, and confined within narrow bounds, are ſlender, and grow tall, but not ſtrong.

The organization and life of *plants* will be farther evinced in the ſequel of this article by many conſiderations, deduced from their anatomy, generation, œconomy, and vegetation.

Plant is a general name, under which are compriſed all vegetable bodies, as trees, ſhrubs, and herbs.

Trees are defined to be perennial *plants*, which riſe to a very great height, with a ſimple, woody, and durable ſtem or trunk: and by theſe characters they are accurately diſtinguiſhed from herbs, whoſe ſtems are frequently compound, herbaceous, or ſucculent, and die down to the root every year. Theſe differences ſuggeſted the very ancient diviſion of vegetables into herbs and trees; ſo that, from the time of Ariſtotle and Theophraſtus, this diviſion has obtained a principal place in almoſt every ſyſtem, except that of Linnæus, which mixes herbs, ſhrubs, and trees promiſcuouſly together: and thus is preſerved the harmony of his ſyſtem, which is ſolely founded on the fructification of every individual genus and ſpecies. Among the celebrated names in botany, which have retained the ancient diſtinction, are numbered Cæſalpinus, the father of ſyſtematic botany, Moriſon, Hermannus, Chriſtopher Knaut, Boerhaave, Ray, Pontederæ, and Tournefort. On the oppoſite ſide are ranged Rivinus, Chriſtian Knaut, Linnæus, Ludwig, &c. The diſtinction into trees and ſhrubs, though of equal antiquity, is neither ſo obvious, nor are its limits ſo accurately aſcertained.

The learned Dr. Alſton, in his Tyrocinium Botanicum, wiſhes to conſider the diſtinction into trees and ſhrubs, as a true natural diſtinction, and endeavours to trace its foundation in the internal ſtructure of the *plants* themſelves. All trees, ſays he, whether they bear buds or not, are covered with two barks, the outer and inner, called by the botaniſts *cortex* and *liber*.

Shrubs differ from herbaceous vegetables in the duration of their ſtems; from trees, in the nature of their covering, which is not a bark but a cuticle or ſimple ſkin: but this fact is not ſufficiently aſcertained. The farther diſtinction into ſhrubs and under-ſhrubs, which is exceedingly arbitrary and indeterminate, was firſt ſuggeſted by Cluſius, in a work intitled Rariorum & Exoticæ Plantæ, publiſhed in 1576, and adopted by Cæſalpinus and others. See Dr. Hunter's edition of Evelyn's Sylva, p. 2. note *.

From the obſervations of Malpighi, Dr. Grew, M. Reaumme, Bradley, and others, there appears a great ſimilitude between the mechaniſm of *plants*, and that of animals; the parts of the former bear a conſtant analogy to thoſe of the latter; and the vegetable and animal œconomy appear both formed on the ſame model. To give an idea hereof, it will be neceſſary to deſcribe the parts whereof *plants* conſiſt.

PLANTS, *anatomy of*. The general and obvious parts of a *plant* are five, *viz.* the root, the ſtem, the branches, the leaves, and the flower. A good microſcope diſcovers the conſtituent parts of a *plant* to be, 1. A very thin outer rind. 2. An inner rind, much thicker than the former. 3. A blea, of a ſpongy texture. 4. A vaſcular ſeries. 5. A fleſhy ſubſtance, which anſwers to the wood of a tree or ſhrub. 6. Pyramidal veſſels, contained within the fleſh. And 7. A pith. Whatever part of the *plant* we examine, we obſerve theſe and no more. The root, its aſcending ſtalk, and deſcending fibre, are one, and not three ſubſtances. This reduces the entire vegetable to one body; and what appears in the flower to be many parts is only compoſed of the extremities of theſeven above mentioned. The cup terminates the outer bark; the inner rind ends in the outer petals; the blea forms the inner petals; the vaſcular ſeries ends in the nectaria; the fleſh makes the ſtaments; the pyramidal veſſels form the receptacle; the pith furniſhes the ſeeds and their capſules.

Trees, ſhrubs, and herbs are organized in the ſame manner; but the colour and thickneſs of their component parts are different, according to their reſpective natures.

1. The outer bark, which firſt preſents itſelf to view, has the appearance of a fine film full of irregular meſhes, though in reality it conſiſts of two membranes, with a ſeries of veſſels between them. Theſe take their courſe upwards, and as they advance towards the cup of the flower, inoſculate with the ſmall veſſels of the inner bark, into which they pour part of the juices they have received from the earth and atmoſphere. The fine meſhes ſerve the purpoſes of inhalent or exhalent pores, according to the circumſtances of the weather.

2. The inner bark is much thicker than the outer. It is made up of ſeveral flakes laid evenly upon one another, each of which conſiſts of two membranes, incloſing a ſeries of veſſels. Theſe communicate freely through the whole ſubſtance of the rind, and as they inoſculate with the veſſels of the outer bark, ſo they alſo communicate with thoſe of the blea.

3. The blea lies immediately under the inner bark. It is a ſingle ſubſtance of uniform ſtructure, of conſiderable thickneſs, and made up of beds of hexagonal cells; in the angles formed by theſe cells, we obſerve the veſſels of the blea, which pour their contents into the cells, that appear to be reſervoirs for the water imbibed by the *plant*. Underneath the blea lies,

4. The vaſcular ſeries, whoſe ſtructure is extremely ſimple, being a ſingle courſe of greeniſh veſſels lodged between two membranes. At a certain ſeaſon of the year, the juices of the vaſcular ſeries are very mucilaginous. Its veſſels have a free communication with the wood and blea. The favourers of a circulation aſſert, that through theſe veſſels, which Mr. Bradley calls the venal veſſels, the returning ſap deſcends; but by the moſt accurate experiments of Dr. Hales, it appears that the vegetable juices do riſe and fall in the ſame ſeries of veſſels, and conſequently have no CIRCULATION.

5. The wood, or fleſhy part of a *plant* is that in which the life of the vegetable ſeems to be placed. It is univerſal in the *plant*, and made up of ſtrong fibres. From this all the other parts are produced; it ſhoots a pith inward, and a rind, blea, and vaſcular ſeries outward. Through every part of the wood or fleſh, there are veſſels, called by the advocates of circulation, arterial veſſels, that convey a juice highly elaborated, the greateſt part of which has undergone the concoction of the rinds, blea, and vaſcular ſeries. The woody fibres conſtitute an order of veſſels, which are named trachææ. Theſe are filled with elaſtic air, and may be diſcovered by the eye, in the wood of all trees. The trachææ form an arterial ſyſtem, and ſupply the place of the heart in animals. Being filled with air, they become ſubject to the alternate effects of heat and cold.

6. The pyramidal veſſels ſpread through the whole ſubſtance of the fleſh, and, as they advance upwards, their ramifications inoſculate, ſo as to prevent any poſſible obſtruction of the ſap. Their juices are very highly elaborated, having paſſed through all the orders of ſap-veſſels. Their ſides are conſtantly in contact with the trachææ; ſo that they are at all times ſubject to the viciſſitudes of the weather. The pyramidal veſſels communicate with,

7. The pith, which is found in all trees, ſhrubs, and *plants*, occupying the centre, but not always regularly continued. When examined by a microſcope, it has the appearance of a number of veſicles, and is of an uniform ſtructure. It does not appear to be abſolutely neceſſary to vegetation, becauſe elms and other trees live and thrive without it. In trees it is found in the branches, being obliterated in the trunk. The veſſels of the fleſh communicate with it, from which it receives a fluid, and it is probably the receptacle of part of the ſap; it is alſo diſcovered in tranſverſe ſections of the ribs of leaves; and when minutely traced, it is found to run up to the ovarium, where it forms the ſeeds and their capſules.

The fibres of a root are ſuppoſed to be ſimple capillary tubes; but upon a minute inſpection, we diſcover them to conſiſt of the ſeven component parts of a *plant*. At their extremities we obſerve a ſpongy kind of excreſcence pierced with innumerable ſmall holes, through which the nutritive juices of the earth are abſorbed, and which Boerhaave conſiders as analogous to the lacteals in animals. When a *plant* has been pulled up, it will be retarded in its growth, until nature has renewed that ſpongy nipple. The bark and leaves of a *plant* imbibe, at proper ſeaſons, the moiſture of the atmoſphere: at other times they perſpire the ſuperfluous nouriſtment. The leaves are broad, in order the more readily to receive the moiſture of the air. The roots are formed ſharp and pointed, to make their paſſage more eaſily through the earth. But experiments ſhew, that a young tree may have its branches placed in the earth, and its roots elevated in the air; and in that inverted ſtate it will continue to live and grow. The air contains, eſpecially during the ſummer months, all the principles of vegetation, which are greedily abſorbed by the veſſels of the leaves and bark; and conveyed to the innermoſt parts of the *plant* for its growth and fructification. When the air happens to be cold and moiſt, this abſorption takes place; when it is hot and dry, the ſame veſſels throw off the ſuperfluous moiſture by perſpiration.

PLANTS, *œconomy, or uſe of the parts of*. The analogy, that ſubſiſts between *plants* and animals, has induced ſome very eminent naturaliſts to ſuppoſe a regular circulation of the vegetable juices. M. Perrault, M. Major, M. Marriotte, Malpighi, and Grew, contended, much about the ſame time, for the CIRCULATION *of the ſap*.

According to their microſcopical obſervations, the wood

of trees and the flesh of *plants* conſiſt of fine capillary tubes, which run parallel from the root, through the trunk and branches. Theſe they looked upon as arteries. Other minute veſſels were obſerved running between the wood and inner bark, which they diſtinguiſhed by the name of veins. They alſo deſcribed very correctly, the tracheæ or air-veſſels, which take their courſe through the fibres of the wood. From theſe preliminaries they reaſoned in this manner: the root having abſorbed a quantity of juice from the earth, it is made to aſcend through the veſſels of the wood, by the alternate expanſion and contraction of the tracheæ, aſſiſted by the natural abſorption of the ſap-veſſels themſelves. They ſuppoſe the ſap to be rarefied to the degree of a fine vapour, in which ſtate it mounted upward to the extreme parts of the *plant*, where, meeting with the external air, it became condenſed into a liquor, and in that form, returned to the root by the veſſels, between the wood and bark.

Dr. Hales, in the moſt ſatisfactory manner, exploded this doctrine, and ſubſtituted another in its place, more conſonant to reaſon and experiment: and it is remarked, that, as Dr. Harvey eſtabliſhed the *circulation of the* BLOOD, in oppoſition to moſt of the anatomiſts in Europe, Dr. Hales clearly diſcovered the CIRCULATION *of the ſap*, againſt the opinion of almoſt every naturaliſt of his time.

In order to have a diſtinct view of the motion of the ſap, it is neceſſary to reflect, that the root, ſtem, branches, and leaves are conſtructed in the ſame manner. Sallows, willows, vines, and moſt ſhrubs, will grow in an inverted ſtate, with their tops downward in the earth. Dr. Bradley deſcribes the manner of inverting a young cherry-tree, the roots of which will put forth leaves, and the branches become roots. Hence it is evident, that the nutritive matter may be conveyed by the leaves as well as by the roots, their veſcular ſtructure being the ſame.

For underſtanding the motion of the ſap, according to theſe principles, it is to be conſidered, that, during the heat of a ſummer's day, all plants perſpire freely from the pores of their leaves and bark. At that time the juices are highly rarefied. The diameters of the tracheæ, or air-veſſels, are enlarged, ſo as to preſs upon and ſtraiten the veſſels that carry the ſap; in conſequence of which, their juices, not being able to eſcape by the roots, are preſſed upward, where there is the leaſt reſiſtance, and perſpire off the excrementitious parts by the leaves and top-branches, in the form of vapour. When the ſolar heat declines, the tracheæ are contracted: the ſap-veſſels are enlarged, and the ſap ſinks down in the manner of the ſpirits of a thermometer. In conſequence of this change, the capillary veſſels of the leaves and top-branches become empty. Being ſurrounded with the humid vapours of the evening, they fill themſelves, from the known laws of attraction, and ſend down the new-acquired juices to be mixed with thoſe that are more elaborated. As ſoon as the ſun has altered the temperature of the air, the tracheæ become again diſtended, and the ſap-veſſels are ſtraitened. The ſame cauſe always produces the ſame effect; and this alternate aſcent and deſcent through the ſame ſyſtem of veſſels, continues as long as the *plant* ſurvives. The irregular motion of the ſtem and branches is another cauſe that contributes to the aſcent of the ſap. Whenever theſe parts are agitated by the air, they are made to aſſume a variety of angles, whereby the ſap-veſſels are ſuddenly ſtraitened. The contained juices, conſequently, receive reiterated impulſes, ſimilar to what happens to the blood of animals from the contraction of the heart. Theſe obſervations convey a general idea of the motion of the ſap, which varies according to the temperature of the weather; which is ſeldom the ſame in any ſucceeding moment: and, therefore, the ſap muſt ſometimes move quick, and ſometimes ſlow. It may riſe and fall many times in a day, puſhed upward by ſudden heats, and falling by ſudden cold. Thus the juices are blended, and the ſecretions forwarded.

As to the manner in which the nutritive juices of the earth and atmoſphere are conveyed into the ſap-veſſels, we are to conſider, that the outer bark which covers every external part of the vegetable, as well below as above the ſurface, is full of perſpiratory or abſorbent holes. The veſſels of this bark, being endowed with the power inherent in capillary tubes, draw up the moiſture that is applied to their ſurface. From them it is committed to the veſſels of the inner bark. After receiving ſome degree of meliioration, the ſap is delivered to the bleа, from the bleа, it paſſes, by anaſtomoſing canals, to the veſcular ſeries. From thence to the wood or fleſh, where it receives its laſt concoction. The nutritive particles, being ſeparated by the mechaniſm of theſe numerous canals, are applied towards the ſuuſiſtence and increaſe of the *plant*; while the watery and excrementitious parts are carried expeditiouſly to the leaves, where they are perſpired off in the form of vapour.

It is evident, however, that, as water contains but few particles that are fit for nouriſhment, it was neceſſary that *plants* ſhould have a power of imbibing a large portion of that fluid. For which reaſon the ſun-flower, conſidered bulk for bulk, takes in ſeventeen times more nouriſhment than a man, and conſequently perſpires more. Air, likewiſe, which contains the life of vegetables, as well as of animals, and which exiſts in two ſtates, both elaſtic and fixed, paſſes in both ſtates into the abſorbent veſſels of *plants*, and, mixing with their juices, circulates through every part.

Dr. Hales, in his Statical Experiments upon the Vine, diſcovered in aſcending with the ſap in the bleeding ſeaſon; and we learn from him that *fixed air* conſtitutes near one third part of the ſolid contents of the heart of oak: and it is found to bear the ſame proportion in peas, beans, and other vegetable ſubſtances. From the combinations of the nutritive particles thus received, a number of different fluids are prepared in the ſame *plant*.

The univerſal juice of a *plant* is a limpid ſub-acid liquor, which, as it moves through the innumerable ſmall veſſels, becomes more and more concocted, and is the general maſs from which all the juices are derived. It may be called the blood of the *plant*. By a certain modification it produces high-flavoured oils, gums, honey, wax, turpentine, roſin, and even the conſtituent parts of the *plant* itſelf. See *Food of* PLANTS.

PLANTS, *generation of*. All *plants* are produced from ſeeds, as all animals are produced from eggs, and the proceſs of nature is very ſimilar in both kinds of generation. The ſmalleſt vegetables have ſeeds, though often not diſcoverable by the naked eye: Valiſneria has diſcovered the ſeeds in ducks-meat, and Micheli has diſcovered them in the mucor and byſſus; Bobart in the ferns; Linnæus in the moſſes; and Reaumur in the fungi. Miſſletoe is alſo known to be produced from ſeed; and the teſtile and flat fungoſes, which ſome conſider as morbid excreſcences, are now known to be true ſpecies of thoſe agarics, which are furniſhed with caps and ſtems, and grow on the ground, whoſe ſeeds falling on a moiſt tree, produce, as it were, half caps without ſtems. Beſides, that ſeeds are the eggs of *plants* appears from hence, that as every egg produces an offspring ſimilar to the parent, ſo do alſo the ſeeds of vegetables, and, therefore, they alſo are eggs. A ſeed reſembles the egg of a hen; as this, as well as the egg, has a ſhell, external membrane or film, a membrane incloſing the yolk, the yolk itſelf, and the ſcar or point of life. In ſeeds the white is wanting, becauſe the moiſture of the earth ſupplies its place, and nouriſhes the embryo of the *plant*. When the flower is going off, the ſeed begins to ſwell, and on the outſide there is ſeen a veſicle, which is the amnion of Malpighi, furniſhed with an umbilical chord or navel-ſtring, which is produced through the chorion to the oppoſite ſide of the egg. While with the egg, the amnion increaſeth, on its top is obſerved another ſmall body, which likewiſe increaſeth continually, till it has filled the whole chorion and egg; and the amnion and chorion are turned into the external ſhell or coat of the ſeed. Thus, as the ſame changes are brought about on the ſeed as in the egg, the ſeeds muſt be the eggs of *plants*. Farther, that *plants* ſpring from eggs, is plain from the lobes, which, when we ſpeak of ſcows and ſimilar quadrupeds, are nothing elſe than ſeveral ſecundines, always adhering to the fœtus, drawing their ſupply of fluids from the matrix, which fluids they prepare for the nouriſhment of the tender fœtus. That moſt *plants* have ſeminal leaves or lobes is very well known. Theſe ſeminal leaves once conſtituted the whole ſeed, except the hilum, or little heart, in which is the point of life; and theſe lobes prepare the nouriſhment for the very tender plant, until it be able to ſtrike root in the earth; in the ſame manner as the yolk in an egg, becoming the placenta, prepares the nouriſhment, and feeds it by the navel-ſtring to the chick; after which they drop off. Hence it appears, that the ſeminal leaves are the lobes; but ſince all lobes proceed from the egg or ſeed, we may fairly conclude that *plants* are produced from eggs. But as no egg can produce an animal, till it be impregnated or fecundated by the male, it will be neceſſary to inveſtigate the ſituation of the genital organs deſtined by nature for this purpoſe in *plants*.

It is plain, that the genital organs of *plants* muſt be ſituated where the ſeeds are produced, but the ſeeds are produced where the flower and fruit are; therefore the flower and fruit are the genital organs of *plants*. And as there was never a clear and evident example produced of any plant which wanted flowers and fruit, though they might not be diſtinctly known on account of their exceeding minuteneſs, we may juſtly ſay, that the eſſence of *plants* conſiſts in their fructification. Moreover, as generation

precedes the birth in animals, the flower in *plants* always precedes the fruit; and, therefore, we are neceſſarily led to aſcribe fecundation to the flower, and the birth or excluſion of the ſeed to the ripe fruit. The flower may, conſequently, be defined to be the genital organs of a *plant*, ſerving for fecundation, and the fruit to be the genital organs ſerving for the birth or maturation of the ſeed. And ſince we know that there are many *plants*, ſome of which want the calyx, others the corolla, others the filaments of the ſtamina, and others the ſtyle, but that all flowers, the meſſes only excepted, are furniſhed with the antheræ or ſtigmata, or both together; theſe parts muſt conſtitute the eſſence of the flower. If we find a flower with antheræ, but no ſtigmata, we may alſo aſſuredly find another flower either in the ſame, or a different *plant* of the ſame ſpecies, which has ſtigmata with the antheræ, or without them. The act of fecundation is performed in the flower, and, therefore, the genital organs of both ſexes muſt be preſent in the flower; not, indeed, always in one and the ſame flower, but it is ſufficient that thoſe of the male be in *one* flower, and thoſe of the female in the other; and theſe genital organs are the antheræ and ſtigmata. The antheræ, or male organs of generation in flowers, are nothing elſe but the bodies which prepare and contain the male ſperm; therefore theſe antheræ are the teſticles together with the ſeminal veſicles, and their duſt the genuine male ſperm of *plants*, anſwering to thoſe particles which are called animalcules in the male ſperm of animals. This propoſition may be evinced by the following arguments: the antheræ and their duſt always come before the fruit; and when they ſhed their duſt, which they do before the flower has attained its full vigour, they have performed their office, and then they drop and become uſeleſs. Beſides, the antheræ are ſo ſituated in the flower, that their duſt, which is the male ſperm, may reach the piſtil or female organs; for the ſtamina either ſurround the piſtil, as in moſt flowers, or if the piſtil incline to the upper ſide of the flower, the ſtamina do the ſame; or if the piſtil nod, the ſtamina aſcend.

Farther, the antheræ and ſtigmata are in full vigour at the ſame time, both when they are in the ſame flower and when they are in ſeparate flowers. Moreover, if we cut aſunder the antheræ before they have ſhed their duſt, their ſtructure will be found altogether as wonderful and curious as that of the ſeed-veſſels themſelves; for within they conſiſt of one, two, three, or four cells, and they open either longitudinally, or at the baſe, ſeparating into pieces or valves, or from the top, or at the two points or horns. And, if we cut off the antheræ of any plant which bears but one flower, taking care at the ſame time that no other *plant* of the ſame ſpecies is near it, the fruit proves abortive, or at leaſt produces ſeeds which will not vegetate. Finally, the figure of the fertilizing duſt will clearly convince any one that this fine powder is not accumulated by chance, or from the dryneſs of the antheræ. Malpighi, Grew, Moreland, and Geoffroy, who have viewed the figure of theſe particles with good microſcopes, found all of them exactly equal to one another, but in different genera as great a difference in ſhape and figure as the ſeeds themſelves ever have. The powder of the antheræ, in point of fecundation, anſwers to Leeuwenhoeck's animalcules in the male ſperm; and the ſtigma which receives this duſt is always moiſtiſh, that the duſt may inſtantly adhere or ſtick to it. That the ſtigmata, which are the other eſſential parts of a flower, are the female organ of generation, may be proved by the following conſiderations: the parts of the piſtillum are the germen, the ſtyle, and the ſtigma; the germen, or ſeed-bud, while the *plant* is in flower, is always imperfect and immature, being only the rudiment of the future fœtus; the ſtyle is no eſſential part, for it is wanting in many ſpecies of *plants*; but the germen can never bring the fruit to maturity, except it be within the flower along with the ſtigma. Hence it follows, that the ſtigma is that part of the flower which receives the impregnating duſt. This will farther appear, if we conſider, that the ſtigma is always ſo ſituated, that the antheræ, or their impregnating duſt, can reach it: moreover, it has always a figure peculiar to itſelf, ſo that in moſt (though not all) *plants* it is double when the fruit conſiſts of two cells; triple when the ſeed-veſſel has three cells; quadruple when it has four cells, &c. Again, the ſtigmata are always in full vigour at the ſame time with the antheræ; beſides, the ſtigmata in moſt *plants*, when they have diſcharged their office, drop off in the ſame manner as the antheræ do; which proves, that the ſtigmata contribute nothing to the ripening of the fruit, but ſerve only for the purpoſe of generation. If the ſtigmata be cut off before they have received the impregnating duſt of the antheræ, the *plant* is caſtrated as to the female organs, and the fruit periſhes. The ſtigma of the flower has, beſides, two other ſingular properties: viz. that it is always diveſted of the cuticle or film, that has it any bark as the other parts have, and then it is always bedewed with a moiſture. Upon the whole it appears, that the *generation of plants* is accompliſhed by the antheræ ſhedding their duſt on the ſtigmata. It is not ſufficiently clear, in what way the generation of animals is accompliſhed; but thus far we are certain, that the male ſperm muſt come in contact with the female organ, if there be any impregnation. In the vegetable kingdom the genital duſt is carried by the air to the moiſt ſtigmata, where the particles burſt and diſcharge their exceeding fine or ſoluble contents, which impregnate the ovary. This will appear if it be conſidered, that when a *plant* is in flower, and the duſt of the antheræ flying about, part of this duſt viſibly lights upon and clings to the ſtigma; the ſtamina and piſtillum are generally of the ſame height, that the male duſt may more eaſily come at the ſtigma, and in thoſe *plants* where this is not the caſe, a ſingular proceſs of fecundation may be obſerved; thus in the African tree crane's-bill, or *geranium inquinans*, where the piſtillum is ſhorter than the ſtamina, the flowers before they blow are pendulous, but upon their opening they ſtand upright, that the powder may fall upon the ſtigma; after which they again nod till the fruit is ripe, and then ſtand upright a ſecond time, that their ſeeds may be more eaſily ſcattered about. In ſome of the pinks, the piſtilla, which are longer than the ſtamina, are bent back like ram's horns towards the antheræ.

Again, the ſtamina for the moſt part ſurround the piſtillum, ſo that ſome of the duſt is always blown by the wind on the ſtigma. Moreover, the ſtamina and piſtillum come at the ſame time, not only in one and the ſame flower, but alſo where ſome are male and others female, on the ſame plant, very few excepted.

Farther, in almoſt all ſorts of flowers we ſee how they expand or open by the heat of the ſun, but in the evening and a moiſt ſtate of the air, they cloſe or contract their flowers, leſt the moiſture getting to the duſt of the antheræ ſhould coagulate the ſame, and render it incapable of being blown on the ſtigma; but when once the fecundation is over, the flowers neither contract in the evening, nor yet againſt rain.

The culture of palm-trees furniſhes a deciſive confirmation of the ſame doctrine of vegetable generation. That the cultivators of the common palm-tree or date-tree, cut off the male ſpadixes, and place them over the females, is recorded by Theophraſtus, Pliny, Proſper Alpinus, Tournefort, Kæmpfer, and others; and if they neglect to do this, the dates are harſh, bad-taſted, and many trees wholly deſtitute of nuts or fruit. The date-tree is every year thus impregnated in Arabia, Perſia, and Egypt, by the inhabitants. The wind does on many occaſions ſerve as a vehicle for bringing the farina of the males to the females. M. Geoffroy cites a ſtory from Joſius Fontanus, who relates, that in his time there were two palm-trees, the one male, cultivated at Brindiſi, the other female, in the wood of Otranto, fifteen leagues apart; that this latter was ſeveral years without bearing any fruit; till at length, riſing above the other trees of the foreſt, to as it might ſee (ſays the poet) the male palm-tree at Brindiſi, it then began to bear fruit in abundance. M. Geoffroy makes no doubt but that the tree then only began to bear fruit, becauſe, it was in a condition to catch on its branches the farina of the male brought thither by the wind. In the male and females of the piſtachia nut-tree they obſerve the ſame method as in thoſe of the date-tree. We may obſerve farther, that ſince the male duſt is generally of greater ſpecific gravity than the air, in moſt plants that have the piſtillum longer than the ſtamina, the all-wiſe Creator has made the flowers nodding, that the powder may more eaſily reach the ſtigma. With reſpect to thoſe *plants*, whoſe ſtems grow under water, the flowers, a little before they blow, emerge or riſe above the ſurface of the water; and thoſe, all whoſe parts grow under water, about the time of flowering, raiſe their flowering ſtems above the water, which ſtems ſink again as ſoon as the time of flowering is over. A ſimilar concluſion may be farther eſtabliſhed from the conſideration of all ſorts of flowers; but enough has been ſaid to prove, that the generation of *plants* is performed by the genital duſt of the antheræ falling on the moiſt ſtigma or female organ, which duſt, by the help of the moiſture, adhers and burſts, diſcharging its contents, the ſubtile particles of which are abſorbed by the ſtyle, into the ovarium, germen, or ſeed-bud. However, the duſt of the antheræ does not penetrate through the ſtyle to the germen and rudiments of the ſeed, as ſome writers have ſuppoſed: the contrary appears to be the caſe from opening a flower of the Oriental rough poppy, with a large flower, cutting its piſtillum perpendicularly downwards; and the ſame-

le or folds, the placentæ and the small seeds sticking to them will be found of a pure white colour, though at the same time the style and all the stigma are wholly tinged with a purple hue from the dust of the antheræ. Hence we may conclude, that not one grain or particle of the farina enters the folds of the receptacle or seeds themselves.

We may close this account with observing upon the whole, that the calyx is the marriage-bed, in which the stamina and pistilla, the male and female organs, celebrate the nuptials of *plants*, and where they are cherished and defended from external injuries: the coroila or petals are the curtains, closely surrounding the genital organs, in order to keep off storm, rain, or cold; but when the sun shines bright, they freely expand, both to give access to the sun's rays, and the fecundating dust: the filaments are the spermatic vessels by which the juice, secreted from the *plant*, is carried to the antheræ; the antheræ are the testicles, and may not improperly be compared to the soft roe or milt of fishes: the dust of the antheræ answers to the sperm and seminal animalcules; for though it is dry, that it may be the more easily conveyed by the wind, yet it gets moisture upon touching the stigma: the stigma is that external part of the female organ, which receives the male dust, and on which the male dust acts: the style is the vagina or tube, through which the effluvia of the male dust pass to the germen or seed-bud: the germen is the ovary, for it contains the unimpregnated or unfertilized seeds: the pericarpium or seed-vessel, answers to the impregnated ovary, and in fact, is the same with the germen or seed-bud, only increased in bulk and loaded with fertile seeds; the seeds are the eggs. Moreover, the calyx is a production of the external bark of the *plant*: the coroila of the inner bark; the stamina of the alburnum or white sap; the pericarpium or seed-vessel of the woody substance; and the seeds of the pith of the tree; for in this manner they are placed, and in this they are also unfolded; so that in the flower we find all the internal parts of a *plant* unfolded.

The stomach of *plants* is the earth, from which they receive their nourishment, and the finest and most subtile parts of its soil is their chyle: the root, which carries the chyle from the stomach to the body of the *plant* is analogous to the lacteals or chyliferous vessels of animals: the trunk, which supports and gives strength to the whole plant, is analogous to the bones: the leaves, by which *plants* transpire, are instead of lungs, and they may be also compared to the muscles of animals, for by their agitation with the wind the *plant* is put in motion; on which account herbs furnished with leaves cannot thrive, except they have air; but succulent *plants* which have no leaves, though shut up in green-houses and quite deprived of the external air, thrive very well: heat is to *plants* analogous to the heart in animals, for they have no heart nor have they occasion for any; because they live like polypes in the animal kingdom; their juices mixed with air being propelled through their vessels, but not circulated back again by returning vessels. *Plants* have generally their genital organs placed at their ramifications, as animals have theirs at the ramification of the iliac vessels, with this difference, that the ramifications of *plants* ascend, whereas those of animals go downwards or backwards; whence the ancients called a *plant* an inverted animal. Pliny observes, that there is in *plants* a natural instinct to generation, and that the males by a certain blast, and subtile powder do consummate the nuptials on the females. See Hunter's edit. of Evelyn's Sylva, p. 216, &c. notes.

For the manner wherein the farina fecundifies, M. Geoffroy advances two opinions:—1. That the farina being always found of a sulphureous composition, and full of subtile penetrating parts (as appears from its sprightly odour) falling on the pistils of the flowers, there resolves, and the subtilest of its parts penetrating the substance of the pistil and the young fruit, excite a fermentation sufficient to open and unfold the young *plant*, inclosed in the embryo of the seed. In this hypothesis the seed is supposed to contain the *plant* in miniature, and only to want a proper juice to unfold its parts, and make them grow. The second opinion is, that the farina of the flower is the first germ or bud of the new *plant*, and needs nothing to unfold it, and enable it to grow, but the juice it finds prepared in the embryon of the seed.

These two theories of vegetable generation, the reader will observe, bear a strict analogy to those two of animal generation; viz. either that the young animal is in the semen masculinum, and only needs the juice of the matrix to cherish and bring it forth; or that the animal is contained in the female ovum, and needs only the male seed to excite a fermentation, &c.

M. Geoffroy rather takes the proper seed to be in the farina; inasmuch as the best microscopes do not discover the least appearance of any bud in the little embryos of the grains, when examined before the apices have shed their dust. In leguminous *plants*, if the leaves and stamina be removed, and the pistil, or that part which becomes the pod, be viewed with the microscope, before the flower be opened; the little green transparent vesiculæ, which are to become the grains, will appear in their natural order; but still shewing nothing else but the mere coat or skin of the grain. If the observation be continued for several days successively, in other flowers, as they advance, the vesiculæ will be found to swell, by degrees to become replete with a limpid liquor; wherein, when the farina comes to be shed, and the leaves of the flower to fall, we observe a little greenish speck, or globule, floating about at large. At first there is not any appearance of organization in this little body; but in time, as it grows, we begin to distinguish two little leaves like two horns. The liquor diminishes insensibly, as the little body grows, till at length the grain becomes quite opake; when, upon opening it, we find its cavity filled with a young *plant* in miniature; consisting of a little germ or *plumula*, a little root, and the lobes of the bean, or pea, &c.

The manner wherein this germ of the apex enters the vesicula of the seed, is not very difficult to determine. For, besides that the cavity of the pistil reaches from the top to the embryon of the grains, those grains or vesiculæ have a little aperture corresponding to the extremity of the cavity of the pistil, so that the small dust, or farina, may easily fall through the aperture into the mouth of the vesicula, which is the embryo of the grain. This cavity, or cicatricula, is much the same in most grains, and it is easily observed in peas, beans, &c. without the microscope. The root of the little germ is just against this aperture, and through this it passes out when the little grain comes to germinate.

The process of nature in the generation of vegetables, and the apparatus she has contrived for that purpose, are so curious, and withal so little known among us, that we shall illustrate them farther with figures; taking the melon for our example, in regard the parts of generation are here very distinct.

By the way it must be observed, that though the melon contains both sexes, yet the disposition of the organs differs, here, from that of the tulip: in effect, on the melon *plant* are two distinct flowers, or blossoms, the one doing the male office, the other the female; which we shall therefore call the *male* and *female flowers*.

In *Tab. Nat. Hist. fig.* 10. is represented the male flower or blossom of the pumpion, a plant of the melon kind, the leaves being stripped from the circle F F. A B E represent the head, placed in the centre of the flower, and formed of the circumvolutions of the apices B, and sustained by four columns, G G G G. The part B of the head represents the circumvolutions of the apices while yet thus; and the part E represents them open, and covered with the farina, which they before contained, but which is diffused on the outside when the *plant* arrives at maturity. Each apex forms a kind of canal separated by a partition into two. A grain of the farina is represented by D. H represents the pedicle that sustains the flower, and which in the male flower produces nothing.

Fig. 11. represents the female flower, or blossom of the pumpion, or that which bears the fruit. The leaves are stripped off the circle F F, as before, the better to shew the other parts. The knot of the flower, or the embryo of the fruit, is represented by A. The pistil is represented by B B; and is only a continuation of the embryo of the fruit A. The top of the pistil spreads in B B into several oblong bodies, each separable into two lobes. These bodies are very rough, furnished with hairs and little vesicles proper to catch the dust of the male flower, and to conduct them to the mouths of the canals, which communicate as far as the cells of the grains contained in the young fruit. Upon cutting the pistil transversely in its smallest part, we find as many canals as there are divisions in its head; which canals correspond to as many little cells, each including two orders of grains, or seeds, ranged in a spongy placenta.

This doctrine of generation affords us a hint how to alter, improve, &c. the taste, form, and quality, of fruits, &c. viz. by impregnating the flower of one, with the farina of another of the same class.

To this accidental coupling and intermixing it is, that the numberless varieties of new fruits, flowers, &c. produced every year by our gardeners, with many other phenomena in the vegetable kingdom, are to be ascribed.

PLANTS, *diseases of*. See DISEASES *of Plants*.
PLANTS, *fecundity of*. See FECUNDITY, and *propagation of* PLANTS, *infra*.
PLANTS, *flowering of*. See FLOWERING.
PLANTS, *food, pabulum, or pasture of*, is the matter of their nourishment

nourishment and increase. What this matter is, has been the subject of considerable dispute. We shall endeavour in the sequel of this article to collect the principal opinions that have occurred to us on this subject, and to state what appears to be the most rational and the most conformable to the latest experiments and observations. The ancients, in general, ascribed to the earth the power of producing *plants* and animals; and for this reason they gave it the general title of parent earth, and mother of all things. They supposed that into this common parent all things returned again at last; and that after a time of dissolution in its bowels, they reverted back again into the formation of more bodies of the same kind. Even those among them, who asserted the doctrine of the four elements, allowed that the earth was the matter which constituted those bodies, and that the other three, that is, fire, air, and water, served only to convey and distribute this as occasion required; and Thales is only misunderstood, when he is supposed to deviate in his opinion from this general system of the ancients.

But though the ancients generally ascribed to the earth the power of producing animals and other bodies, the moderns have adopted another opinion, viz. that water is the origin of all. Lord Bacon was one of the first who argued on this principle: he says, that *plants* derive their nourishment principally, if not altogether, from water; and that the earth only serves to keep the stalk upright, and to defend the root from an excess of heat or of cold. Since the time of this great author, many have been more express in asserting and more positive in defending this opinion; and they have affirmed, that water is the only principle of all natural things, supposing that, by some secret process of nature, water is transmuted into stones, *plants*, and other substances. Helmont attempted to establish this doctrine by many experiments: and Mr. Boyle, who followed him through the whole course of his experiments, seems to assent to his opinion, that water is transmuted by nature into wood and stone; though, in his usual way, he delivers his thoughts with great modesty and caution.

The two principal facts upon which their opinion is founded, are that of mint and some other *plants* growing in water; and that of a tree being planted in a small quantity of earth, which, being baked to a dryness, and weighed before the tree was set in it, and again baked, and weighed afterwards, will be found to have lost nothing of its own weight; though the tree has increased to a very great degree, merely, as they say, from the water with which they have, from time to time, moistened this earth.

To the last experiment it might be objected, that it is not easy to bake earth to the same degree of dryness twice over, so as to have any hopes of being exact in the weight; but allowing the greatest possible degree of exactness, the experiment must be inconclusive, unless it could be proved that the water which was used was pure and homogeneous, and not charged with any terrestrial matter: for if it were, the plant might owe its increase to that alone, and the water only serve, according to the doctrine of the ancients, to convey and distribute this grand nourishing element, in a necessary and proper manner. Water always contains a solution of animal and vegetable substances; and these may constitute the nourishment of *plants*, whilst the element, in which they are suspended, acts only as a vehicle, in guiding them through the fine vessels of the vegetable body. In conformity to the first experiment, it has been alledged, that the hyacinth, and other bulbous roots are known to perfect their flowers in pure water. See FLOWERING *of Plants*.

Hence superficial observers have deduced an argument in favour of water being the food of vegetables.

But the truth is, the roots, stem, and flowers of such *plants* are nourished by the mucilaginous juices of the bulb, diluted by the surrounding water: this mucilage is just sufficient to perfect the flower, and no more. Such a bulb neither forms seeds, nor sends forth off-sets; at the end of the season, it appears weak, shrivelled, and exhausted, and is rendered unfit to produce flowers the succeeding year. A root of the same kind, that has been fed by the only and mucilaginous juices of the earth, essentially differs in every particular. It has a plump appearance, is full of mucilage, with off-sets upon its sides.

That water is the food of vegetables has been also argued, from setting a sprig of balm, mint, or such plant in a phial of pure water, without any mixture of earth; in which state the sprig grows, and puts forth roots, leaves, and branches. Agreeable to which is another experiment of Van Helmont; who, drying two hundred pounds of earth, and planting a willow which weighed five pounds in it, watered it only with rain or distilled water; and to secure it from any earth, covered it with a perforated tin cover; at five years end, weighing the tree with all the leaves it had borne in that time, he found it to weigh one hundred and sixty nine pounds, three ounces; yet the earth was only diminished two ounces.

Dr. Woodward has made many experiments, with a view of ascertaining this point; from the result of which he draws conclusions favourable to the opinion which has very generally prevailed, till of late, that earth is the nutriment of *plants*. Most of his experiments were made with sprigs of mint, and some other *plants*, nicely weighed and inclosed in equal glass phials, well covered up with parchment; leaving room for the stems to ascend through it, and filled with water; some with spring water, others with rain water, and others with Thames water. At the end of seventy-seven days, he took them all out again, and weighed them, and also the water left; and computed the weight of water expended on them, and the proportion of the increase of the plant to the expence of the water. The next year, viz. 1692, he made fresh experiments with the same phials and the same sorts of *plants*, weighed as before, only some were filled with Hyde-park conduit water alone, others with the same water, and a certain proportion of garden earth dissolved in it; and others with the same water distilled. At the end of fifty-six days, he weighed the *plants*, waters, &c. and computed what each plant had gained, what quantity of water was expended on the *plant*, and the proportion of the increase of the *plant* to the decrease of the water.

The result of all these experiments he gives us in the following observations and reflections. 1. In *plants* of the same kind, the less they are in bulk, the smaller quantity of the fluid wafts, in which they are set, is drawn off: the consumption, where the mass is of equal thickness, being nearly proportional to the bulk of the *plant*. In reality, the water seems to ascend up the vessels of *plants* in much the same manner as in a filtre; and, therefore, it is no wonder, that the larger filtre should draw off more water than the smaller: or that a *plant*, which hath more and larger vessels, should take up a greater share of the fluid in which it is set, than one that has fewer. 2. Much the greater part of the fluid mass, thus drawn off and conveyed into the *plants*, does not settle or abide there, but passes through their pores and exhales up into the atmosphere. See *Perspiration of* PLANTS. The least proportion of the water expended was to the augment of the *plant* as 46 or 50 to 1; and in some as 109, 200, nay in one as 700 to 1. Nor does this humidity go off alone; but it usually carries with it many parts of the same nature with those, of which the *plant*, through which it passes, consists: the grosser, indeed, are not so easily borne up into the atmosphere, but are usually deposited on the surface of leaves, flowers, and other parts of the *plant*; whence proceed our manna, honeys, and other plentiful exudations of vegetables; but the finer and lighter parts are with greater ease transmitted to the atmosphere, where they are conveyed to our organs of smell, and by the air we draw in respiration; and they are pleasant or offensive, beneficial or injurious to us, according to the nature of the *plants* from which they arise. And as these owe their rise to the water that ascends out of the earth, through the bodies of *plants*, we may hence perceive the reason why they are more numerous in the air in wet summers, and a greater quantity of odours is found exhaling from vegetables in warm humid seasons, than in any other. 3. A great part, says Dr. Woodward, of the terrestrial matter that is mixed with water ascends up into the *plant*, as well as the water. There was much more terrestrial matter, at the end of the experiment, in the water of the glasses that had no *plants* in them, than in those which had *plants*. The garden mould dissolved in some of the glasses was considerably diminished and carried off: nay the terrestrial and vegetable matter was borne up in the tubes filled with sand, cotton, &c. in such a quantity as to be evident to sense; and the bodies in the cavities of the other tubes, that had their lower ends immersed in water, wherein saffron, cochineal, &c. had been infused, were tinged with yellow, purple, &c. Marine *plants*, he observes, absorb mineral matter with the vegetables. As for the vegetable matter, this is so fine and light, as to be surprisingly adapted and disposed to attend water in all its motions, and into each of its recesses: for if water be percolated with all the care imaginable, and filtered over so many times, yet some terrestrial matter will remain. Dr. Woodward filtered water through several sheets of thick paper, and afterwards, through very close fine cloth, twelve times doubled; and this he did repeatedly: and yet a considerable quantity of this matter discovered itself, after all his pains, in the water. Hence he reasons, that if it there passes interstices that are so very small and fine, along with the water, it is less strange that it should attend it in its passage

through the ducts and vessels of *plants*: and although in filtering and distilling the water, some of the earthy matter with which it was before impregnated is intercepted, and made to quit it, yet that which remains in the water after these operations is fine and light, and such as, in his apprehension, is peculiarly fit for the nourishment and growth of vegetables. This, he says, is the case of rain-water; the quantity of terrestrial matter in it is not great; but it is chiefly of the light kind, and is perfectly dissolved and reduced to simple corpuscles, fit to enter the tubules and vessels of *plants*; on which account this water is so fertile and prolific. The reason why all the terrestrial matter mixed with the water does not ascend into the *plant* is, that the mineral matter comprises a great part of it; and this is not only gross and ponderous, but fixed and inflexible, and not disposed to enter the pores of the roots; besides many of the simple vegetable particles, by degrees, unite and form small clods or molecules, which adhere to the extremities of the roots; and others of them, entangled in a loose manner, form the substance or green bodies so commonly observed in stagnant waters: these, when thus combined, are too large to enter the pores or attend up the vessels of *plants*, which simply they might have done.

We shall here observe, that this green matter is itself a *plant*, probably belonging to the genus of CONFERVA. The seeds of it are invisible in the air, insinuate themselves into vessels of water, through the smallest apertures, and then diffuse themselves through the whole mass of it: and are capable of producing *plants* in all seasons of the year, whenever they meet with water, especially if it be impregnated with a proper proportion of vegetable or animal substance, or a state of putrefaction. But though the richest pabulum for this *plant* is the nutritious parts of animal and vegetable substances, some of them are unfavourable to it, and prevent its growth.

Dr. Priestley has made many curious *experiments* on this green matter, or water-moss, as he calls it; and shews how powerfully the influence of light, it contributes to depurate or disembarrass the air previously contained in water.

Of *earth*, *water*, and *air*.

Hence it is, as Dr. Woodward proceeds, that to ASCERTAIN, let the earth be ever so rich, good, and fit for the production of corn, or other vegetables, little will come of it, unless the parts of it be separated and loosened; and it is on this account, such gains are bestowed in digging, plowing, fallowing, harrowing, and otherwise tumbling the cloddish lumps of earth; and thus, Dr. Woodward says, sea-mud, marle, and other salts promote vegetation.

Mr. Tull has founded his new system of HUSBANDRY, to a great measure, on this principle, that earth is the food of *plants*. The increased fertility of a well pulverized soil induced him to imagine that the plough, &c. could do nothing more than divide the particles of earth, as to fit them for entering into the roots of *plants*. The mouths of the vessels destined to take in the food or nourishment of the *plant* are all situated on the convex surface of the roots; and these, according to him, take their pabulum or food, which is extremely small particles of earth, blended with a due proportion of water, from the superficies of the pores or cavities within which the roots are included. It is certain, he says, that the earth is not digested for this purpose by any other means than by the roots of *plants*: for actual fact shews, that where no vegetables are suffered to be, the ground will always grow the richer. Plough it or harrow it as often as you please; let it be exposed to the sun in hot, dry, parts all the summer, and to the frosts all the winter; let it be covered by water at the bottom of ponds and ditches, or grind it to fine powder; the longer it is exposed or treated by any or all of these methods, or in any other possible way, except actual fire be used, the more fertile it will be. Those particles, which are the pabulum of *plants*, are so extremely subtile and light, as not to be much attracted to the earth, if separated from those parts to which they adhere, or with which they are in contact. They adhere in the earth like dust on the surface of a smooth clay, which, though you turn it up and down, still remains in its place, as these particles do to those parts of the earth, till they are removed by some external agent. The proper agent for this purpose is the root of a *plant*, but this cannot act upon them unless they are first moistened by water, which dissolves to some extent, and goes with them into the mouths of the vessels in the roots. It is necessary also that the parts of the air come in contact with the matter of this pabulum, in order to relax and render it fit to be separated and imbibed by the roots of those *plants* which are in the way of it. As to the size of the particles of the pabulum of *plants*, it is not unlikely that the roots may take in some grosser than those on which the colours of bodies depend; but to discover the magnitude of these corpuscles, Dr. Hooke thinks will require a microscope that will represent things five or six hundred times bigger than they appear to the eye at a foot distance, and that with sufficient distinctness. We are well assured, he adds, that the fine particles of the food of *plants*, after they have been reduced into the bodies of *plants*, do perspire through their pores in a large quantity, and fly off into the air; which affords a proof, that they are not to be separated from the parts of the earth with which they are in contact, otherwise than by means of *plants*; for if they could, then all our stirring and digging the earth would make it the poorer, by giving them occasion to evaporate; the contrary of which is found by experience. Water alone affords, in appearance, nourishment to *plants*, since they will grow in water; but this water is allowed never to be free from earth; and that makes it so very nutritive to *plants*, even when just descending in rain. This is the earthy matter, which is properly the pabulum, or food of *plants*, which is continually in great abundance evaporated from *plants* and trees into the air, and in a manner fills the whole atmosphere about them; this is not to be embodied in the watery vapours in their ascent, and again brought down to the earth in showers of rain with them. Hence it is no wonder that rain water proves so very nutritive to *plants*, since it contains the very matter of their food, ready separated from the rest of the earth, and mixed in that vehicle with which, and by means of which alone, it can be received into the bodies of *plants*, through the mouths of the vessels of their roots. The pores, cavities, and interstices of the earth being of two sorts, viz. natural and artificial, the one adapted to the natural, the other to artificial pasture for *plants*; all depending on the different nature of the interstices or cavities of the earth. But from the system of Mr. Tull, it seems to follow, that all this, equally good, would prove equally prolific. It is certain, that an open soil, if not too light in its own nature, will always produce plentiful crops; because it readily receives the air, rains, and dews into its bosom, and at the same time gives the roots of *plants* a free passage or smell of food. This seems to be the true reason why land well tilled is so remarkably fruitful. But to return to the further reasoning of Dr. Woodward. Some authors imagine nitre essential to *plants*; but this author affirms on, that by all the trials he has been able to make, the case is quite otherwise, and that nitre, when contiguous to the *plant*, destroys instead of nourishing it. But nitre, and other salts, loosen the earth, and thus dispose its parts to be attenuated by the water, and carried up into the food or *plant*, for its formation or increase. In the same way, lime is likewise serviceable to vegetation: the husbandman say, it does not famen, but only mellows the ground; rendering it more capable of entering the foods of vegetables let in it, in order to its nourishment, than otherwise it would have been.

4. The *plant*, according to Dr. Woodward, is more or less nourished in proportion as the water in which it stands, contains more or less proper terrestrial matter in it. The truth of this proposition, he infers, from the whole process of his experiments. The mint in one of his glasses was of much the same bulk and weight with that of two or three others; but the water in which the first was, being river-water, which was apparently more copiously furnished than the others with terrestrial matter, this occasioned it to arrive at almost double their bulk, and with a less expence of water: so likewise the mint in another glass, in which water was dissolved a small quantity of good garden mould, though it had the disadvantage of being last, when first set, than either of the mints in two other glasses, whose water was the same with the first, without any mixture of earth in it, yet, in a short time, the plant merely overtook it in growth, but much out-stripped the others. However, Dr. Woodward is of opinion, that every kind of vegetable, and even every part of the same vegetable, requires a peculiar and specific matter for its formation and nourishment; so that if the soil in which any vegetable or seed is planted, contains all or most of the proper ingredients for its composition, and these in due quantity, it will grow and thrive; otherwise it will not prosper at all, or not attain its natural stature; and it will be defective in taste, smell, colour, or some other respect. Besides, the soil once proper for the production of some sort of vegetable does not always continue to be so, but in length of time less or more, as it becomes barren; the vegetative matter with which it was accustomed, being reduced and lurking, bearing another succession of the same vegetables, it must be supplied with a new fund of matter similar to that which it contained at first, either by lying fallow and ex-

posed to the air and rain, or by being manured. And this simply consists chiefly of the parts of vegetables or of animals. Many facts of this kind, which Dr. Woodward alledges, point out a peculiar terrestrial matter, and not water, for the subject to which *plants* owe their increase; for if it were water only, there would be no need of manure or transplanting; since the rain falls in all places and, perhaps, these facts and even the doctor's reasoning upon them, would lead us to presume, that some other substance, which pervades the terrestrial matter under peculiar modifications of it, may be necessary for the purposes of vegetation; as we shall see more particularly in the sequel of this article.

5. Vegetables, Dr. Woodward concludes, are not formed of water, but of a certain terrestrial matter. A little distillation shews, that there is a considerable quantity of this matter contained in rain, spring, and river-water; and experiments shew, that the much greatest part of the fluid mass that receives into *plants* does not settle or abide there, but passes through their pores and exhales into the atmosphere; and that a great part of the terrestrial matter, mixed with the water, passes up into the *plant* along with it; and that the *plant* is more or less augmented, in proportion as the water contains a greater or smaller quantity of that matter: from all which we may reasonably infer, that earth, and not water, is the matter that constitutes vegetables. One of the sprigs of mint drew up into it two thousand five hundred and one grains of the fluid mass, and yet had received but three and $\frac{1}{2}$ grains of increase from it: a second, though it was at first less than the third, yet, being set in water with which earth was plentifully mixed, and the other in water without such earth, had very much outgrown it; weighing, at last, one hundred and forty five grains more than the former: a fourth *plant*, though at first much less than the fifth, yet, being set in the foul thick water, that was left in the still, after that in which the last was set was drawn off, had gained in weight, at the end, above double what that in the finer and thinner water had gained. The proportion of the augment of that *plant* which those mull was to the fluid mass spent upon it but as one to forty-six; in others as one to fifty, one hundred, two hundred, and in the categoric but as one to seven hundred and fourteen. One of the sprigs took up thirty-nine grains of water a day, one day with another; which was much more than the whole *plant* weighed originally, and yet it gained not $\frac{1}{3}$ of a grain a day in weight; and another took up two hundred and fifty-three grains a day, which was near twice as much as its original weight; and after all the daily increase of the *plant* was no more than $2\frac{1}{2}$ grains.

6. Spring and rain-water contain nearly an equal charge of vegetable matter; and river-water more than either of them. Their proportions hold in the main, though, for various reasons, a strict and just comparison is hardly to be expected. Some rivers abound with this matter more than others; of this we have a remarkable instance in the Nile, the Ganges, and other rivers, that yearly overflow the neighbouring plains; their lands producing the largest crops of any in the world.

7. Water serves only for a vehicle to the terrestrial matter which forms vegetables, and does not itself make any addition to them. Where the proper terrestrial matter is wanting, the *plant* is not augmented, though ever so much water ascend into it; so that water is not the matter that compoles vegetable bodies: this is only the agent that conveys the matter to them, and distributes it to their several parts for their nourishment: that matter is sluggish and inactive, and would be eternally confined to its beds of earth, without advancing up into *plants*, if water or some such instrument did not draw it forth, and convey it to them. This fluid is fit for such a necessary vehicle on various accounts; the figure of its parts, which are exactly spherical, renders it fit for motion and for moving other bodies; the intervals of such parts are, with respect to their bulk, larger than those of any other; and, therefore, the fittest to receive and contain other matter in them: the constituent corpuscles of water are also, singly considered, absolutely solid, and do not easily yield to any external force, which secures their figure, and, consequently, their intervals from any alteration. Water is further capacitated to be a vehicle for this matter by the tenacity of the corpuscles of which it consists; so that they will pass through pores and interstices, which are impassable to air and any other fluid. Thus they are capable of entering into the finest tubes and vesicles of *plants*, and of introducing the terrestrial matter with them, conveying it to all their parts; whilst each, by means of organs with which it is endued for this purpose, intercepts and assumes to itself such particles, as are suitable to its own nature, letting the rest pass on through the common duct.

8. Water is not capable of performing this office to *plants*, unless it is assisted by a due degree of heat. This must concur, or vegetation will not succeed. The *plants* set to the gasses in October and the following colder months, had not nearly the quantity of water conveyed into them, or nearly such an additional increase, as those that were set in June and the better months. The particles of water are perceptible of every impression, and are eafily put into motion by heat. Besides, it is observable in autumn, that as the sun's power is gradually less and less, so its effect on *plants* is remitted, and vegetation slackens by little and little. Its failure is first observable in trees, next in shrubs, and then in herbs and the lower tribes of vegetables; the heat being, at length, not sufficient to supply even those which are to near the earth and the fund of their nourishment. As the heat returns in the succeeding spring, they will recruit again, and are furnished with fresh supplies and verdure; the lowest first, then the shrubs, and lastly the trees. The greater the heat given to *plants* to a certain degree in the natural way, the sooner they pass through the several stages of fructification. In the northern regions, e. gr. in Lapland, where the greater part of the year is subject to intense and inceslant frosts, the summer season affords an excessive heat for two months, the sun never setting in all that time. This season comes on towards the latter end of June, and the grass and other herbs then first begin to appear in their young shoots above the ground; but after this vegetation is carried on with such speed, that in a fortnight the flowers of the herbs and trees are expanded, and the leaves attain to their full size and maturity. Thus, as the heat of the several seasons affords us a different face of things, so the several distant climates exhibit the different scenes of nature, and productions of the earth. The hotter countries ordinarily yield the largest and tallest trees, and in greater variety than the colder; and those *plants* common to both attain to a much greater bulk in the southern than in the northern climes; nay, there are some regions so cold, that they raise no vegetables at all to any considerable size: thus we learn from Greenland, Iceland, and other places of like cold situation: in these there are no trees, and the shrubs are poor, small, and low. We also find, that even in the warmer climates, if there happen a remission or diminution of the usual heat, their productions are always impeded in proportion. But it is not merely the sun, or the ordinary emission of the subterranean heat, that promotes vegetation, but likewise any other, according to its degree and power; as we find from our stoves and hot-beds.

Such are the systems of vegetation, that have been founded on the supposition, that water or earth is the principal pabulum of *plants*. *See* Food *of Plants*.

Modern experiments and discoveries have loft the way to another theory with respect to the food of *plants*, that seems to be less exceptionable than either of the former. Dr. Hales, whose experiments and reasoning on the subject of vegetation have been deservedly applauded, observes, that the substances of vegetables appear, by a chemical analysis, to be composed of sulphur, volatile salt, water, and earth; which principles, he says, are all endued with mutually attracting powers; and also of a large portion of air, which has a wonderful property of strongly attracting, in a fixed state, or of repelling in an elastic state, with a power which is superior to great compressive forces; and it is by the infinite combinations, action, and re-action of these principles, that all the operations in animal and vegetable bodies are effected. These active aereal principles are very serviceable in carrying on the work of vegetation to its perfection and maturity; not only in helping by their elasticity to dilate and subtilize part, but also by enlivening and invigorating their hopwhere, uniting with the other mutually attracting principles, they are by gentle heat and motion let at liberty to stimulate into the nourishment of the respective parts. The sum of the attracting powers of these mutually acting and re-acting principles is, while in this nutritive state, superior to their repelling power; whereby the work of nutrition is gradually advanced by the nearer and nearer union of these principles from a less to a greater degree of consistency, till they are advanced to that viscid ductile state, whence the several parts of vegetables are formed; and are at length firmly compacted into hard substances, by the flying off of the watery dilating vehicle: but when they are again dissolved by the watery particles, then repelling power is thereby become superior to their attracting power, and the union of the parts of vegetables is so thoroughly dissolved that putrefaction commences. Of these principles of vegetables they are found greater proportions at out in the more exalted and elaborate parts, as in the seeds and flowers. Hence it is argued, that nature's chief business in bringing the parts of a vegetable, especially its fruit and seed, to maturity,

is to combine together in a due proportion the more active and noble principles of sulphur and air, that chiefly constitute oil, which in its more refined state is never found without some degree of earth and salt in it.

Dr. Hunter, so well known, and so justly celebrated both as an anatomist and naturalist, is induced by a number of experiments, accurately conducted, to believe, that all vegetables receive their principal nourishment from oily particles incorporated with water, by means of an alkaline salt, or absorbent earth. Till oil is made miscible, it is unable to enter the radical vessels of vegetables: and, on that account, Providence has bountifully supplied all natural soils with chalky or other absorbent particles; and those soils which have been assisted by art are full of materials for that purpose; such as lime, marl, soap-ashes, and the volatile alkaline salt of putrid dunghills. Natural soils receive their oily particles from the air or atmosphere, which, during the summer months, is full of putrid exhalations arising from the steam of dunghills, the perspiration of animals and insects; and every shower brings down these oleaginous particles for the nourishment of *plants*. All rich soils, in a state of nature, contain oil, and in lands that have been ploughed for some years, it is found in proportion to the quantity of putrid dung that is laid upon them, allowance being made for the crop they have sustained. By attending to the effects of manures of an oily nature, Dr. Hunter apprehends that we must be satisfied, that oil, however qualified, is one of the chief instruments of vegetation. Thus, rape-shell, laid on land, is a certain and speedy manure, as it contains the food of *plants* ready prepared: soot is also an oily manure, but different from the former, because it contains alkaline salt, in its own nature calculated as well for opening the soil, as for rendering the oily parts miscible with water: the dung of pigeons, which feed chiefly upon grains and oily seeds, is a rich and lasting manure: the dung of horses that are kept in stables, and fed upon beans, oats, and hay, which contain much oil, is also a strong manure, more especially when it has undergone the putrid ferment, in order to mix and assimilate its oily, watery, and saline parts. Swine's dung is of a dispositions and oily nature, and perhaps is the richest of the animal manures. The dung of ruminant animals, as cows and sheep, is preferable to that of horses at grass, owing to the quantity of animal juices mixed with their food in chewing; and the latter the animal, *cæteris paribus*, the richer is the dung. Human ordure, which is full of oil and a volatile alkaline salt, is of itself too strong a manure for any land: the dung of carnivorous animals is plentifully stored with oil; animals that feed upon fowls and grains come next, and after them follow those which subsist upon grass only.

Besides, the argument in favour of oil being the principal food of *plants*, is confirmed by the observation, that all vegetables, whose seeds are of an oily nature, are found to be remarkable impoverishers of the soil, as hemp, rape, and flax; and the best manures for lands worn out by these crops are such as have a good deal of oil in their composition, provided that they are laid on with lime, chalk, marl, or soap-ashes, so as to render the oily particles miscible with water.

Farther, oily particles constitute the nourishment of *plants* in their embryo state; and by a fair inference we may suppose that something of the same nature is continued to them as they advance in growth. The oily seeds, as rape, hemp, line, and turnip, consist of two lobes, which, when spread upon the surface, form the seminal leaves, in these the whole oil of the seed is contained. The moisture of the atmosphere penetrates the cuticle of the leaves, and, mixing with the oil, constitutes an emulsion for the nourishment of the *plant*. The oleaginous liquor being consumed, the seminal leaves having performed their office decay. The leguminous and farinaceous *plants* keep their placenta, or seminal leaves, within the earth; in which situation they supply the tender germ with oily nutriment, until its roots are grown sufficiently strong to penetrate the soil. See VEGETATION.

It has been a received opinion, that lime enriches the land, upon which it is laid, by supplying it with a salt fit for the nourishment of *plants*; but by all the experiments that have been made upon lime, it is found to contain no kind of salt. Its operation, therefore, should be considered in a different light: by the fermentation which it occasions, the earth is opened and divided, and, by its absorbent and alkaline quality, it unites the oily and watery parts of the soil. It seems also to have the property of collecting the acid of the air, which it readily forms into a neutral salt, of great use in vegetation. It is probable, therefore, that lime tends to rob the soil of its oily particles, and will, in time, render it barren, unless care be taken to support it with rotten dung, or other manures of an oily nature. Its great excellence, however, upon a sandy soil, is by mechanically binding the loose particles, and thereby preventing the liquid parts of the manure from escaping out of the reach of the radical fibres of the *plants*. Upon clay its effect is different, for, by the gentle fermentation it produces, the unsubdued soil is opened and divided; the manures laid on readily come into contact with every part of it; and the fibres of the *plants* have full liberty to spread themselves. Clay, well limed, will fall in water, and ferment with acids; and in these circumstances, the air, rains, and dews, are freely admitted, and the soil is unable to retain the nourishment which they respectively afford. In consequence of a fermentation raised in the soil, the fixed air is let at liberty, which, in a surprising manner, promotes vegetation.

To the universal principle of oil, Dr. Hunter adds another of great efficacy, which is the nitrous acid of the air. The existence of such a principle is demonstrable from the method of making salt-petre in different parts of the world. See NITRE.

And though experiments have not yet ascertained the efficacy of nitre, considered as a manure, Dr. Hunter considers it as a vivifying principle in the process of vegetation.

In order to conceive how *plants* receive their nourishment, we must recur to the analogy that is known to subsist between *plants* and animals. Oil and water seem to make up the nourishment of both. Earth enters very little into the composition of either. It is known that animals take in a great many earthy particles at the mouth, but they are soon discharged by urine and stool. Vegetables take in the smallest portion imaginable of earth; and the reason is, they have no way to discharge it. It is highly probable, that the radical fibres of *plants* take up their nourishment from the earth, in the same manner that the lacteal vessels absorb the nutriment from the intestines; and as the oily and watery parts of our food are perfectly united into a milky liquor, by means of the spittle, pancreatic juice, and bile, before the orifices of the lacteals, we have all the reason imaginable to keep up the analogy, and suppose that the oleaginous and watery parts of the soil are also incorporated, previous to their being taken up by the absorbing vessels of the *plant*. To form a perfect judgment of this, we must reflect that every soil, in a state of nature, has in itself a quantity of absorbent earth, sufficient to incorporate its inherent oil and water; but when we load it with fat manures, it becomes essentially necessary to bestow upon it, at the same time, something to assimilate the parts. Lime, soap-ashes, kelp, marl, and all the alkaline substances, perform that office. In order to render this operation visible to the senses, dissolve one drachm of Russia pot-ash in four ounces of water; then add one spoonful of oil; shake the mixture, and it will instantly become an uniform mass of a whitish colour, adapted to all the purposes of vegetation. This easy and familiar experiment is a just representation of what happens after the operation of BURN-*baking*, and, consequently, may be considered as a confirmation of the hypothesis advanced. In this process, the sward being reduced to ashes, a fixed alkaline salt is produced; the moisture of the atmosphere soon reduces that salt into a fluid state, which, mixing with the soil, brings about an union of the oily and watery parts, in the manner demonstrated in the experiment. When the under-stratum consists of a rich vegetable mould, the effects of burn-baking will be lasting; but when the soil happens to be thin and poor, the first crop frequently suffers before it arrives at maturity. The farmer, therefore, who is at the expence of paring and burning a thin soil, should bestow upon it a portion of rotten dung, or thambles manure, before the ashes are spread, in order to supply the deficiency of oily particles: in this way, the crop will be supported during its growth, and the land will be preserved in health and vigour. But *plants* not only receive nourishment by their roots, but also by their leaves. Vegetables that have a lanceolate leaf, such as vetches, peas, beans, and buck-wheat, draw a great part of their nourishment from the air, and on that account impoverish the soil less than wheat, oats, barley, or rye, the leaves of which are of a firmer texture. Rape and hemp are oil-bearing *plants*, and, consequently, impoverishers of the soil, but the former less so than the latter, on account of the greater succulency of its leaf. The leaves of all kinds of grain are succulent for a time, during which period the *plants* take little from the earth; but as soon as the ear begins to be formed, they lose their softness, and diminish in their attractive power. The radical fibres are then more vigorously employed in extracting the oily particles of the earth, for the nourishment of the seed. Dr. Hales observes, that the leaves of *plants* serve, not only as excretory ducts to separate and carry off the redundant watery fluid, which, by being long detained in the plants, would turn

turn rancid and prejudicial to them; but likewise to imbibe the dew, and rain, which contain salt, sulphur, &c. and to be of the same use to *plants*, that the lungs are to animals. However he adds, that as *plants* have not a dilating and contracting thorax, their inspirations and expirations will not be so frequent as those of animals, but depend wholly on the alternate changes from hot to cold for inspiration, and *vice versâ* for expiration. But the greater part of their nourishment is derived from the roots. These, therefore, are found to bear a considerable proportion to the body of the *plant* above ground; the superficies of the former being above four-tenths of that of the latter. Hence appears the necessity of cutting off many branches from a transplanted tree; because in digging it up, a great part of the roots is cut off. See *Oeconomy and use of the parts of* PLANTS, and *Perspiration of* PLANTS.

The facts above stated, with regard to the influence of putrid air, arising from dunghills and the perspiration of animals, on the nourishment and increase of *plants*, were published by Dr. Hunter in his Georgical Essays, in 1769 and 1770; but they were afterwards ascertained, in the most satisfactory manner, by a variety of curious experiments made by Dr. Priestley, in the years 1771 and 1772, an account of which was presented to the Royal Society, in 1773. Having discovered, that sprigs of mint thrive, in a most surprising manner, in air that had been freshly and strongly tainted with putrefaction, and that was immediately fatal to animal life, he was led to conclude, that *plants*, instead of affecting the air in the same manner with animal respiration, reverse the effects of breathing, and tend to keep the atmosphere sweet and wholesome, when it is become noxious in consequence of animals either living and breathing, or dying and putrefying in it. See AIR *philosophical*.

In order to ascertain this, he took a quantity of air, made thoroughly noxious, by mice breathing and dying in it, and divided it into two parts: one of which he put into a phial immersed in water, and to the other, which was contained in a glass jar, standing in water, he put a sprig of mint. After eight or nine days, he found that a mouse lived perfectly well in that part of the air, in which the sprig of mint had grown, but died the moment it was put into the other part of the same original quantity of air, exposed in the same manner, but without any *plant* growing in it. This experiment was several times repeated, with different kinds of tainted air, and generally with the same success. From these facts he reasons thus: since the *plants* that were made use of manifestly grow and thrive in putrid air; since putrid matter is well known to afford proper nourishment for the roots of *plants*; and since it is likewise certain that they receive nourishment by their leaves as well as by their roots, it seems to be exceedingly probable, that the putrid effluvium is in some measure extracted from the air, by means of the leaves of *plants*; and, therefore, that they render the remainder more fit for respiration.

Dr. Priestley repeated and varied experiments of the same kind, and established the principle, that air, rendered noxious by respiration, putrefaction, the burning of inflammable substances, &c. was restored by vegetation. He also found, that common air is rendered in some measure dephlogisticated by vegetating *plants*, so as to be much more diminished by *nitrous* AIR than before: and also, that *plants do* not grow so well in dephlogisticated air as in common air, which affords a presumption, that dephlogisticated air does not supply that *pabulum*, which *plants* derive even from common air: and farther, that aquatic *plants*, by means of the action of light upon them, depurate the air contained in the water, in which they grow. So that air, combined with water, is liable to be dephlogisticated by vegetation as well as to be phlogisticated by respiration, as much as air in an elastic state, out of water.

Dr. Priestley having ascertained the fact, that vitiated air was restored by vegetation, and considered that common air is vitiated by being combined, in various ways, with PHLOGISTON, (see *Fixed* AIR), was led to conjecture, that this restoration was effected by *plants* imbibing the phlogistic matter with which air is loaded by any of those processes, that tend to injure it. And hence it was natural to conclude, that phlogiston is the principal pabulum or food of *plants*, upon which their nourishment and increase very materially depends. See on the subject of this article, Phil. Trans. N° 253. Dr. Hunter's Georgical Essays, vol. i. Evelyn's Silva, with Dr. Hunter's notes, quarto, 1776. Hales's Statics, vol. i. Priestley's Observations on Air, vol. i. p. 49, 87, vol. iv. p. 299, 305, vol. v. p. 12, &c. See VEGETATION *of Plants*.

PLANTS, *fructification of*. See FRUCTIFICATION, *Oeconomy, &c. of* PLANTS, and *Food of* PLANTS.

PLANTS, *perpendicularity of*. See PERPENDICULARITY.

PLANTS, *perspiration of*. We have already observed under *Oeconomy, &c. of* PLANTS, and *Food of* PLANTS, that vegetables imbibe and perspire moisture and air very copiously. These properties of *plants*, on which their nourishment and vigour depend, are very elaborately illustrated and evinced by Dr. Hales. In order to try what moisture *plants* would imbibe, the shorter cut off several branches of apple-trees, pear, cherry, and apricot-trees; and having immersed them into a known quantity of water, he found some of them imbibing fifteen ounces, some twenty ounces, and others twenty-five or thirty ounces, in twelve hours day; more or less, according to the quantity of leaves they had: and yet when he weighed them at night, they were lighter than in the morning, which undoubtedly was owing to their perspiration. The quantity imbibed decreased very much every day, the sap-vessels being probably shrunk at the transverse cut, and too much saturated with water, to let any more pass, so that usually in four or five days, the leaves faded and withered much. He made the same experiments with elm-branches, oak, osier, willow, fallow, aspen, currant, gooseberry, and filbeard branches; but none of these imbibed so much as the foregoing; and several sorts of evergreens much less. From an experiment with the stem of an apple-tree, he concludes, that the imbibing and perspiring powers of leaves, &c. are proportionable to their surfaces; and thence he infers, that the use of those leaves, which are placed just where the fruit joins to the tree, is to bring nourishment to the fruit. From another experiment with hop-vines, he determined, that one of them with its leaves imbibed in twelve hours day, four ounces, and the other without leaves 4 of an ounce: whence, allowing 1000 hills in an acre of hop-ground, three poles to each hill, and three vines to each pole, so that the number of vines is 9000, each of which imbibes four ounces, the sum of the ounces imbibed in an acre in twelve hours day, will be 36000 ounces = 1576800 grains, = 62047 cubic inches, or 202 ale gallons, which, divided by 6272640 the number of square inches in an acre, will give the quantity of liquor perspired by all the hop-vines, equal to an area of liquor as broad as an acre, and $\frac{1}{100}$ part of an inch deep. In a kindly state of the air, this moisture is daily carried off, so that the hops are kept in a healthy state; but in a rainy moist state of air, the moisture hovering about the hops hinders the kindly perspiration of the leaves, so that the stagnating sap corrupts and breeds mouldy sets, which spoils many hop-grounds. See FIRE-*blight*, and HONEY-*dew*.

Farther, Dr. Hales made several experiments to ascertain the force with which *plants* imbibe moisture. This he did by putting the stump of a branch into one end of a glass tube, cementing it fast, and then immersing the other end of the tube, after being first filled with water, into a cistern of mercury; on which, removing his finger that stopped up the lower end of the tube, the stump imbibed the water with so much vigour, that in six minutes time the mercury was raised eight inches in the tube. For the method of conducting these experiments, &c. see *Aqueo-mercurial* GAGE.

The imbibing force of a great variety of trees being tried in the same manner, by immersing branches of them in aqueo-mercurial gages, it was found that the pear, quince, cherry, walnut, peach, apricot, plum, black-thorn, white-thorn, gooseberry, waterelder, and sycamore, raised the mercury from three to six inches high. The elm, oak, horse-chesnut, filberd, fig, mulberry, willow, fallow, osier, ash, linden, and currant, raised the mercury only one or two inches. But the evergreens, and the following trees and *plants*, viz. laurel, rosemary, laurustine, phyllorea, furze, rue, barberry, jessamine, cucumber-branch, pumkin, and Jerusalem artichoke, did not raise it at all. In another experiment it was found, that the force with which peas dilate by imbibing water, is sufficient to lift up a weight of one hundred and eighty-four pounds laid upon them; and the dilatation of the peas is always equal to the quantity of water they imbibe.

In order to discover with what force the sap of the vine is pushed forth in the bleeding season, the following experiments were made. Dr. Hales cut off a vine on a western aspect, within seven inches of the ground, the remaining stump having no lateral branches, and being four or five years old, and $\frac{3}{4}$ of an inch in diameter. To the top of this stump he fixed a glass tube, twenty-five feet high, securing the joint with stiff cement made of bees-wax and turpentine, besides several folds of wet bladder fastened over it with packthread. As the stem did not at first bleed into the tube, he filled the tube two feet high with water, which the same afternoon was imbibed by the stem within three inches of the bottom. Next day the stem began to bleed so, that the sap in the tube continued rising daily, till it was above twenty-one feet high, and would very probably have risen higher, if the joint had

not several times leaked. In the chief bleeding season, it would continue rising night and day; but much more in the day than night; and most of all in the greatest heat of the day. When the sun shone hot upon the vine, there was always a continued series of air-bubbles ascending from the stem through the sap in the tube, in so great plenty, as to make a large froth on the upper part of the sap, which shews the great quantity of air drawn in through the roots and stem.

This force of the sap is five times greater than the force of the blood in the great crural artery of a horse; seven times greater than the force of the blood in the like artery of a dog; and eight times greater than the blood's force in the same artery of a fallow doe.

The free communication of the sap-vessels of *plants* appears from hence; that though deep gaps or notches be cut in a branch, it will nevertheless imbibe water in the manner already mentioned. In order to try whether it would not be the same in branches, as they grow on trees, the doctor cut two such opposite gaps in a duck-cherry branch, three inches distant from each other, notwithstanding which, the leaves of this branch continued green, within sight or ten days as long as the leaves on the other branches of the same tree.

As to the quantity of moisture perspired by *plants* and trees, there appears to be a very considerable difference in different vegetables. The lemon-tree, which is an evergreen, perspires much less than the sun-flower, or than the vine, or the apple-tree, whose leaves fall off in winter. Thus, from equal areas, the lemon-tree was found to perspire only $\frac{1}{250}$ of an inch in height, during twelve hours of the day in the month of July; the apple-tree $\frac{1}{154}$, a cabbage $\frac{1}{34}$, a vine $\frac{1}{17}$, and a sun-flower $\frac{1}{13}$, in a day and night. Dr. Hales, having taken a pretty exact account of the weight, size, and surface of the sun-flower, and of the quantities imbibed and perspired by it, formed a curious comparison of what is taken in and perspired by a human body, and this plant. The weight of a well-sized man is equal to 160 pounds; the weight of the sun-flower was 3 pounds: so that their weights are to each other as 160 to 3, or as 53:1. The surface of such human body is equal to 15 square feet, or 2160 square inches. The surface of the sun-flower is 4616 square inches; and, therefore, it is to that of the human body as 26:10. The quantity perspired by a man in twenty-four hours is about thirty-one ounces, according to Dr. Keill. The quantity perspired by the *plant* in the same time is twenty-two ounces; so that the perspiration of a man to that of the sun-flower is as 141:100. Abating the 6 ounces of the 31 ounces to be carried off by respiration from the lungs in the 24 hours, the 25 ounces, multiplied by 438, the number of grains in an ounce avoirdupoise, give a product of 10950 grains; which, divided by 254, the number of grains in a cubic inch of water, gives 43 cubic inches perspired by a man; which, divided by the surface of his body, viz. 2160 square inches, gives a quotient, which is nearly $\frac{1}{50}$th part of a cubic inch perspired off a square inch in 24 hours. Therefore in equal surfaces and equal times, the man perspires $\frac{1}{50}$, the *plant* $\frac{1}{70}$, or as 50:35. Dr. Keill, by estimating the quantities of the several evacuations of his body, found that he ate and drank every 24 hours 4 pounds 10 ounces; the sun-flower imbibed and perspired in the same time 22 ounces; so the man's food to that of the *plant* is as 74 ounces to 22 ounces, or as 7:2. But, compared both for both, the *plant* imbibes 17 times more fresh food than the man; for deducting 5 ounces, which Dr. Keill allows for the *faeces alvi*, there will remain 4 pounds 5 ounces of fresh liquor, which enters a man's veins, and an equal quantity passes off every 24 hours. Then it will be found, that 17 times more new fluid enters the sap-vessels of the *plant*, and passes off in 24 hours, than there enters the veins of a man, and passes off in the same time. One reason of this greater plenty of fresh fluid in the vegetable than in the animal body may be, because the fluid which is filtrated through the roots immediately from the earth is not near so full freighted with nutritive particles as the chyle which enters the lacteals of animals; not to add, that the motion of the sap is thereby much accelerated. Since then a plentiful perspiration is found so necessary for the health of a plant or tree, it is probable that many of their diseases are owing to a stoppage of this perspiration by inclement air. It appears also, that the power of perspiration much depends on exposure to the air; and that the perspiring matter is more actuated by warmth and so exhaled, than protruded by the force of the sap upwards. For this purpose the roots of trees and *plants* are, by means of the sun's warmth, constantly irrigated with fresh supplies of moisture from those parts of the earth which are not immediately adjacent to them; which, by the same means, insinuates itself with some vigour into the roots, and ascends, by the principle of attraction, up their fine capillary vessels, and is carried off in perspiration by the action of warmth; without which perspiration the *sap* must stagnate. This perspiration is greatest in the middle of the day, but decreases towards evening, and probably wholly ceases when the dews fall.

In animals it is the heart which sets the blood in motion, and makes it continually circulate; but in vegetables no other cause of the sap's motion can be discovered, but the strong attraction of the capillary sap-vessels, assisted by the brisk undulations and vibrations caused by the sun's warmth, whereby the sap is carried up to the top of the tallest trees, and there perspired off through the leaves; but when the surface of the tree is greatly diminished by the loss of its leaves, then also the perspiration and motion of the sap is proportionably diminished; so that the ascending velocity of the sap is principally accelerated by the plentiful perspiration of the leaves, thereby making room for the fine capillary vessels to exert their great attracting power, which perspiration is effected by the brisk rarefying vibrations of warmth; a power, says Dr. Hales, that does not seem to be in any respect well adapted to make the sap descend from the tops of vegetables by different vessels to the root. This excellent author has urged many arguments to prove, that there is no uniform CIRCULATION *of the sap in trees*, like that of the blood in animals; for this reason, besides others, that if there were such a circulation, the leaves of the ilex grafted upon the English oak would fall in winter equally with those of the oak itself, which is not found to be the case. See *Anatomy, Oeconomy*, &c. and *Food of* PLANTS, *supra*.

PLANTS, *perforation of*. See PERFORATION, &c.

PLANTS, *propagation of*. Though the most natural, as well as most universal method of propagating *plants* is that of sowing the seeds of each kind in a proper soil, yet such is the prolific power of nature, that in some instances, like the polype animal, they may be propagated by sets, pieces, slips, or cuttings, taken from the parent-tree, or *plant*, and set in such a soil as they are known to delight in. The whole family of willows are propagated in this manner with the greatest ease. Those sorts which grow to be large trees, and are cultivated for timber, are generally planted from sets of about seven or eight feet long, sharpened at their larger ends, which are thrust into the ground by the sides of ditches and banks where the ground is moist; in which places they make a considerable progress, and are a great improvement to such effates; because their tops will be fit to lop every fourth or fifth year. The tallows are planted of lesser sets, only three feet long, thrust two feet into the ground, and one foot above it. The rows should be three feet asunder, and the sets in each row eighteen inches; observing always to place the rows sloping, in the same manner as the ground. The best season for planting these cuttings is in February; and if the soil be good, they will produce a great crop of shoots every year, which will produce, at a moderate computation, ten pounds per acre.

Besides the willow kind, the plane-tree, mint, &c. may be propagated in this manner; only it ought to be remarked, that in providing the slips, sprigs, or cuttings, such branches as have knots or joints should be cut off two or three inches beneath them; and that small top sprigs, of two or three years growth, are the best for this operation.

Another way of propagating *plants*, is by parting or dividing their roots, each part of which will, by proper management, thrive and send out fresh roots, which may be separated in the same manner.

The manner of propagating *plants*, by laying the tops of branches in the ground, is described under the head LAYER; and the common way by sowing of the seeds, is sufficiently explained under NURSERY, SOWING, SEED, &c. *Plants* are also propagated by their bulbs.

The number of vegetables that may be propagated from an individual, is very remarkable, especially in the most minute *plants*.

It has been recorded, that in so large a *plant* as the common mallow, the annual product of one seed was no less than 200,000; but it has been since proved, by a strict examination into the more minute parts of the vegetable world, that so despised a *plant* as the common scarlet moss produces a much more numerous offspring. In one of the little heads of this *plant* there have been counted 13824 seeds. Now allotting to a root of this *plant* eight branches, and to each branch six heads, which appears to be a very moderate computation, the produce of one seed is $6 \times 13824 = 82944$; and 8×82944 gives 663552 seeds, as the annual produce of one seed, and that to small that 13824 of them are contained in a capsule, whose

whose length is but one ninth of an inch; its diameter but one twenty-third of an inch, and its weight but the thirteenth part of a grain. Phil. Trans. N° 478, sect. 12. See FECUNDITY *of plants*.

PLANTS, *resuscitation of*, in *Chemistry*. See RESUSCITATION.

PLANTS, *sleep of*, *somnus plantarum*, is that faculty which the leaves of many *plants* have of assuming in the night-time a situation different from what they bear in the day. The term was first used by Linnæus in his treatise on this subject, though the property denoted by it has been long known. Acosta and Prosper Alpinus, who wrote near the conclusion of the sixteenth century, are the first who recorded this nocturnal change in the leaves of *plants*. However, it is an observation of Pliny, Hist. Nat. lib xviii. cap. 35. that the leaves of trefoil assume an erect situation at the approach of storms. The same is observable of our wood-sorrel; and Linnæus adds, of almost all *plants* with decompound flamina. The examples of sleeping *plants* instanced by Alpinus are few; he says, that it was common to several Egyptian species, but specifies only the acacia, abrus, abius, lotus, and the tamarind-tree. Linnæus discovered the same property in many other *plants*; and there is reason to believe, that no *plant* or tree is wholly unaffected by it. This property was ascribed by Ray and many others to the coldness of the evening air; but Linnæus found that this was not the true cause, since *plants* were alike influenced by it when placed in stoves, where the temperature of the air was always the same. Dr. Hill, in his Sleep of *Plants*, ascribes this alternate change of position in the leaves of *plants* to the impulse of light upon their leaves. This is very different from that other property of *plants*, called the VITALE *plantæ*.

PLANTS, *systems of*. Ray's system is delivered below, under the article PLANTS. The system of Linnæus is to be found under FRUCTIFICATION; and the system of Tournefort under PETAL. See BOTANY.

PLANTS, *trachea of*. See TRACHEÆ and *Anatomy of* PLANTS.

PLANTS, *transpiration of*. See TRANSPIRATION.

PLANTS may be divided, with regard to the manner of their generating, into

Male, or such as bear no fruit or seed, and have only the male organ of generation, viz. the farina. Of this kind are the

Male palm-tree, willow, poplar, hemp, nettle, and hop-plant.

Female, or such as bear fruit, and have the female organ; viz. the pistil, or uterus, but want the farina. Such are the *female* palm, willow, poplar, &c.

Hermaphrodites, or such as have both male and female parts, or both the farina and pistil.

These are again subdivided into, 1. Those in whose flower both sexes are united; as the lily, gilliflower, tulip, and much the greater part of the vegetable species, whose pistil is surrounded by the flamina. And, 2. Those whose male and female parts are distinct, and at a distance from each other: such as the rose, whose uterus is beneath the petals; the melon, and all of the cucumber kind, which have their male and female flowers apart; and all fruit, nut, and mast-bearing trees; as the apple, plum, goodberry, and the walnut, hazel, filbert, oak, beech, pine, cypress, cedar, juniper, mulberry, pistachio, &c. which have catkins.

Plants may be again distinguished, with regard to their food, and the element they live in, into

Terrestrial, which are those that live only on land; as oak, beech, flax, &c.

Aquatic, which live only in water; either in rivers, as the water-lily, water-plantain, &c. or in the sea, as the fucus, &c.

Amphibious, which live indifferently either in land or water; as the willow, alder, &c.

Plants are again distributed, with regard to their destined year, or period, into

Annual, which are those whose root is formed and dies in the same year; such are all the leguminous *plants*, wheat, rye, &c.

Biennials, or *triennials*, which only produce flowers and seeds the second, or even third year after their being raised, and then die: such are fennel, mint, &c.

Perennial, which are those that do not die after they have once borne seed. Of these, some are evergreens; as the afarabacca, yew, &c. Others lose their leaves one part of the year; as rugwort, coltsfoot, &c.

Plants, again, are distinguished, with regard to their magnitude, &c. into

Trees, or *bores*; as the oak, pine, fir, elm, sycamore, &c.

Shrubs, or *frutices*; as the holly, box, ivy, juniper, &c. and

Herbs; as mint, sage, fennel, thyme, &c.

With regard to certain remarkable qualities, into inert and *sensitive*, such as give some tokens of sense. On which account they were called, by the ancients, *zoophytomorum*; plants (from *ασχημονεω*, *to be bashful*); and, by the moderns *living* or *animal plants*.

But these divisions are rather popular than just and philosophical.

The botanists give us more accurate and minute arrangement, or distributions, of the vegetable kingdom, into classes, genera, species, &c. with regard to their nature, characters, &c. But it is a point they are not well agreed upon, from what consideration the division into genera is best taken; some, as Gesner, Columna, Tournefort, &c. chusing only the flower and fruit; and others taking in the roots, leaves, stems, &c. See BOTANY.

The classification of Linnæus is now generally followed. Our ingenious Mr. Ray distributes plants into twenty-five genera, or classes, under the following denominations.

1. PLANTS, *imperfect*, which are such as appear to want the flower and seed. These were once a very large tribe of *plants*, but the more accurate observations of the moderns have proved, that most of these *plants* really contained seeds, and those very numerous, though so small as not to appear obvious to the naked eye; and probably the farther discoveries of the microscope will in time leave us no one *plant* deserving the appellation of *imperfect*. In Mr. Ray's time, many whole genera of *plants* were esteemed imperfect; but he includes the several kinds he calls to under three general heads. 1. The submarine. 2. The fungules. And, 3. The moles. But it has been evinced by later authors, that some of these are not plants, and that many of those which really are plants, have true seeds, and it is hence to be hoped of the rest. See CONFERVA of Hair-weed, CORAL, CORALLINES, FUCUS, FUNGUS or MUSHROOM, MUSEUS or MOSS, &c.

2. PLANTS producing an imperfect flower, and whose seed is too small to be discerned by the naked eye: such are fern, polypody, &c.

3. Those whose flowers want petals. Such are hops, hemp, nettles, and docks.

4. Those with a compound flower, and which emit a milky juice when cut or broken; as lettuce, dandelion, succory, &c.

5. Those with a compound flower of a discous form, and whose seed is elated, or, as it were, winged with down; as coltsfoot, fleabane, &c.

6. *Herbæ capitatæ*, or those whose flower is composed of several long tubulous flowers gathered into a round head, and covered with a scaly coat; as the thistle, great burdock, bluebottle, &c.

7. PLANTS, *corymbiferous*, with a discous flower, but no down to the seeds; as the daisy, yarrow, cornmarigold, &c.

8. PLANTS with a perfect flower, and only one seed to each flower; as valerian, agrimony, burnet, &c.

9. PLANTS, *umbelliferous*, with a flower of five petals, and two seeds to each flower. This, being a large genus, is subdivided into seven orders; viz. those with a flat broad seed, as wild garden parsnip; with a longish and larger seed, swelling in the middle, as cow-weed, and wild chervil; with a shorter seed, as angelica; with a tuberous root, as the earth-nut; with a small striated seed, as caraways, saxifrage, and burnet; with a rough hairy seed, as parsly, and wild carrot; and with entire leaves, as fanicle, and thorough-wax.

10. PLANTS, *stellate*, whose leaves go round the stalks, at certain intervals, in form of stars; as clivers, madder, &c.

11. PLANTS, *rough-leaved*, which have their leaves placed alternately, or in no certain order, along the stalks; as hounds-tongue, mouse-ear, &c.

12. PLANTS, *verticillate*, whose leaves grow, by pairs, on their stalks, one leaf right against another, the flower being monopetalous, and usually in form of a lobiate; as thyme, mint, pennyroyal, vervain, &c.

13. *Polyspermous*, or those with many naked seeds, at least five, succeeding their flowers; as crows foot, marshmallows, cinquefoil, strawberries, &c.

14. PLANTS, *baciferous*, or such as bear berries; as briony, honeysuckle, Solomon's seal, lily of the valley, nightshade, asparagus, &c.

15. PLANTS, *multisiliquous*, or *corniculate*, which after each flower produce several long slender siliquæ, or cases, wherein their seed is contained; as orpine, navel-wort, bears-foot, columbines, &c.

16. PLANTS, *vasculiferous*, *with a monopetalous flower*, and which, after each flower, have a vessel beside the calyx, containing the seed; as henbane, bindweed, campions, foxglove, eyebright, &c.

17. Those with *an uniform tetrapetalous flower*, bearing their seeds in oblong siliquous cases; as stockgilly-flower, mustard, radish, &c.

18. PLANTS, *vasculiferous, with a forming tetrapetalous flower*, but of an anomalous or uncertain kind, and, in reality, only monopetalous, falling off altogether in one; as speedwell, fluellin, plantain, yellow and wild poppy, &c.

19. PLANTS, *vasculiferous, with a pentapetalous five-leaved flower*; as maiden pinks, campions, chick weed, St. John's-wort, flax, primrose, wood-sorrel, &c.

20. PLANTS, *leguminous*, or such as bear pulse, with a papilionaceous flower, consisting of four parts joined at the edges; as peas, beans, vetches, tares, lentils, liquorice, trefoil, &c.

21. PLANTS *with a true bulbous root*; as garlic, daffodils, hyacinth, saffron, &c.

22. Those whose roots approach nearly to the bulbous form; as fleur-de-lys, cuckoo-pint, &c.

23. PLANTS, *culmiferous*, with a grassy leaf, and an imperfect flower, having a smooth, hollow-jointed stalk, with a long sharp-pointed leaf at each joint, and the seeds contained in a chaffy husk; as wheat, barley, rye, oats, reeds, and most kinds of grass.

24. PLANTS with a grassy leaf, but not culmiferous, with an imperfect or flamineous flower; as rushes, cat's-tail, &c.

25. PLANTS whose characters are uncertain; chiefly water-plants; as the water-lily, milk-wort, mouse-tail, &c. See FRUCTIFICATION.

PLANTS, *for the fancied transmutation of one species of into another*, see TRANSMUTATION, DEGENERATION, &c.

The properties and virtues of *plants* have been observed, by some naturalists, to bear an analogy to their forms. In the Philosophical Transactions we have a discourse of Mr. James Pettiver, to shew, that *plants* of the same or like figure have the same or like virtues and uses. Thus the umbelliferous tribe, he observes, have all a carminative taste and smell, are powerful expellers of wind, and therefore good in all flatulent disorders. The galeate or verticillate kind are a degree warmer, and more powerful, than the last, and therefore may be reputed aromatic, being proper for nervous disorders. The tetrapetalous kind are hot like the two former, but exert their power in a different way, viz. by a diuretic volatile salt, which makes them of use in chronical diseases, obstructions, cacochymies, &c.

PLANTS, *analysis of*. The common method of attempting the *analysis of plants*, by common distillations, gave hopes that it would prove very useful in determining their virtues; but experiment shewed it to fail of this intent, since the wholesome *plants* and the poisonous ones afforded by this means much the same sort of principles; and on the whole, these appeared in a great measure to be creatures of the fire rather than parts of the subject. This set M. Boulduc of the Paris academy upon trying whether there might not be some way invented at once more simple and more certain; and with this view he attempted to examine the juices and decoctions of several *plants*, to find their essential salts, which had not been procured in their natural state by the chemical trials. The *plant* this gentleman chose as the subject of his experiments in this view, was the common borage.

First, he made a large quantity of a decoction of borage; this he divided into three equal parts: the first of these he evaporated to a pellicle, or to the consistence of a syrup; it was then of a blackish colour, and was charged with a great quantity of oily particles. This being set by for some days in a warm time of the year, covered itself with a thick skin, which was again covered by a mouldiness. When this skin was removed, there appeared underneath a large quantity of crystals, in fine slender filaments like needles, mixed among a large quantity of other crystals, which were small, and of no regular figures; all these were swimming in a liquor of the thickness of a syrup. These long crystals being taken out of the liquor, and laid upon a hot iron, took fire, and flamed in the manner of salt-petre when mixed with any sulphureous substance; and, in truth, this was a salt-petre, yet loaded with the oily matter of the decoction.

Here, therefore, is a clear proof, not only of the nitrous acid being in this plant, but of plain nitre itself; for on pouring oil of tartar on a solution of this salt, there was no precipitation made of any substance whatever; which would have been the case, had there been in this state any earthy matter for its basis.

The second portion of this decoction was divested of its oil by means of lime, and then evaporated to a light pellicle over a very gentle heat. This was set by to rest for some days, and finer and more perfect crystals were found, shot in the form of needles in it; these were truly nitrous, and occupied the upper part of the liquor; below these there were a great number of other cubic ones, which were easily known to be crystals of sea salt.

The long crystals of this operation took fire on a lighted charcoal, and appeared plain nitre; and the others, when dry, crepitated in the fire exactly in the manner of sea salt; and when a solution of them was poured upon a solution of silver, made in spirit of nitre, it immediately occasioned a white curd to appear, which being separated, washed, and put to the fire, became a true luna cornea, being transparent, and easily cut with a knife. Here, therefore, are plain proofs of nitre and sea salt in this *plant*. Mem. Acad. Scienc. Par. 1734.

The third portion of the decoction was poured upon some fresh wood-ashes; and being afterwards evaporated to a pellicle, and set by for some days, there was found in this more nitre than in any of the others; and that whiter and more clear; the others being usually coloured brownish or reddish by the decoction. The occasion of this seems to be, that part of the nitrous acid, which in the other experiments neither joined with any earthy matter, nor with the fatty matter of the decoction, mixed with the salts of the lixivium, made by pouring the liquor which contained it on wood-ashes, and thus yielded a much larger quantity of salt-petre than before.

The fatty substance which covered the first decoction being dried, was found to contain a great quantity of nitre, which it had not sufficient to shoot, or form itself into crystals: this dried cruft being laid on a burning charcoal, took fire in the same manner as if nitre and powder of charcoal had been thrown into a crucible made and hot.

The taste of the *plant* being thus obtained from its decoction, it was determined to try whether the *plant* remaining after the decoction had any more to yield. To try this, it was gently dried in a shade, and burned in a covered vessel to a black coal, and afterwards, in an open fire, to ashes.

Of these ashes there was made a lixivium in the common way, in order to be evaporated for the salt: this lixivium being mixed with syrup of violets, scarce at all altered it from its blue colour, only just bringing on a faint greenishness, which soon went off again, and left the syrup of as fine a blue as before: this made it evident, either that there was very little alkali salt there, or else that it was blended with salts of some other kind, which altered its effects; and this proved to be the true state of the matter on further experiment; for evaporating the lixivium to a pellicle, there very soon shot in it regular and beautiful crystals of a salt, having all the characters of tartarum vitriolatum. A second evaporation of the lixivium afforded more of the same salt, but in smaller crystals. Evaporating the liquor to about half its quantity, and setting it again to shoot, there appeared plain cubic crystals of sea salt; which being strictly examined, were found to be perfect sea salt, no way altered, but having stood the force of the calcination.

After these salts had been separated from the lixivium, it changed syrup of violets immediately to a beautiful green, which colour it always retained.

It is evident from these experiments, that this *plant* affords four different kinds of salts, viz. nitre, sea salt, tartarum vitriolatum, and the common fixed alkali; and it is hence no trivial observation, that the three mineral acids are found here all in one *plant*.

The virtues of *plants* are very variable; a change of climate will alter or destroy them, as we see in many of the medicinal *plants* of other countries brought over hither, which, though they seem to flourish with us, never possess their virtues in the same degree as in their native climate. The bodies of different animals also render the effect of the same *plant* different: the tithymals or spurges are all of them very violent cathartics, when taken by us; but yet they are eaten by goats and several other animals without hurt, or without any purgative effect, and seem to give them a particular share of vigour and spirits. The fish are, on the other hand, more strongly affected by it than we are; for the juice made into paste with flower and honey, poisons, or at least intoxicates them so, that they may be taken out of the water with one's hand. Bitter almonds are of no ill consequence to us, yet they kill all sorts of birds.

PLANTS, *ashes of*. The ashes of a *plant* carefully prepared, retain its exact form till disturbed by accidents. The way of preparing them is this: take a whole *plant* which has been used for the distillation of the oil, water, &c. lay it evenly upon a flat plate of iron, and place this on a clear fire, that no smoke may prevent the success of the operation; continue and raise the fire, till the whole substance of the *plant* appears perfectly ignited. There first arises a light smoke from it; this gradually becomes darker, and at length as black as pitch; the smell of burning increases as the smoke increases; at length the smoke breaks out into flame, and then the smell in a great measure ceases; the *plant* by degrees grows black, within

smoke

ſmoke ariſes, and as ſoon as perfectly black all over, it takes fire. When the flame ceaſes, the leaves appear white; but if any black ſpots remain, there are always ſeen ſparks of fire ſcattering themſelves about on them, till the blackneſs is perfectly conſumed. The aſhes being now become perfectly white, yield no ſmell, nor the leaſt appearance of fire; and they yet retain, after all this violence of fire, the perfect form of the *plant*, even to a microſcopic obſervation: for, if examined by glaſſes, there will be found every feature and lineament of the *plant*, even the hairineſs of the ſtalks or down upon the leaves; every riſing and cavity natural to the *plant* appear alſo diſtinct, and every the ſmalleſt fibre. But this only remains while they are unmoved; the moment they are diſturbed, though but by breathing upon them, the whole falls to duſt, and the form is irrecoverably loſt.

The aſhes thus carefully prepared, are perfectly inſipid and feculeſs; and when lixiviated in the common way for making the fixed ſalt, afford no ſalt at all, but only on the evaporation leave a ſmall quantity of a matter reſembling lime; the remaining aſhes are wholly terreſtrial, and ſerve excellently for the making copels, for the uſe of aſſaying. Boerhaave's Chem. part ii. p. 19.

From this we learn, that the *plant*, by having been previouſly boiled in water in the diſtillation, was diveſted of all its ſalts; and that in general, water, with a great degree of heat, is capable of extracting from any vegetable all its ſaline particles, whether volatile or fixed. We find, however, that water can never ſeparate the fixed oil, which here ſhews itſelf to have wholly remained in the *plant*, by the ſmoke, ſmell, and flame it yields; and by the ſparks of fire in the remaining black parts of the *plant*, which were wholly owing to the remains of this oil, no fire being able to make the ſmalleſt ſpark afterwards appear in the aſhes.

Air, as well as fire, is neceſſary to this oil's taking flame; for in a covered veſſel it will not blaze till the cover is taken off. This thick oil is extremely different from what we call the eſſential oil of a *plant*, and ſeems to be the ſame in all vegetables; and to this they owe their coheſion; while the eſſential oil and ſalt are extracted from the *plant* by boiling, it yet holds together in its native figure and ſtrength; but as ſoon as the black oil is diſſipated by burning, the whole firmneſs of the *plant* is loſt, and a breath of air blaſts it to duſt.

The aſhes of different woods, burnt to perfect whiteneſs, and freed from their alkaline ſalt, have been found to be, in part, of the ſame nature with the true MAGNESIA. Of vegetable aſhes, moderately or ſtrongly calcined, only a part was found to diſſolve in acids, and this part appeared to be perfect magneſia. It is probable that the remainder might be reduced to the ſame ſtate, by repeating the calcination. See POT-*aſhes*.

PLANTS, *juices of*. Moſt juices of vegetables coagulate when expoſed to the air, whether it be that they are drawn out of the *plant* by wounds, or that they naturally run out; though what is called naturally running out, is generally the effect of a wound in the *plant*, from a ſort of cancer, or ſome other internal cauſe. The flowers of the St. John's wort, and the leaves of the rorella, or ſun-dew, afford us purple blebs and veins, and large drops of a clear fluid; yet it does not ſeem certain that theſe are coagulated juices. The ſmall green leaves, forming the cup of the flower of the common erect tuſſan St. John's wort, are ſurrounded with purple blebs, and the points or tops of the leaves alſo have each two or three ſuch blebs, all containing a purple juice; yet the ſtalk of this *plant*, being cut and ever ſo nicely examined, does not ſhew to the naked eye, nor even to the microſcope, any veſſels containing ſuch a purple fluid. Whence it may appear not improbable, that what is thus found in ſmall blebs is a matter ſeparated by coagulation only from the reſt of the juice of the flower.

In the common St. John's wort the edges of all the leaves of the flower are ſurrounded with theſe purple blebs, and the ſtalk, though round, has a double edge, one on each ſide, and the blebs or bags are to be ſeen riſing on theſe edges of the ſtalk. The cup of the flower has ſeveral purple veins, yielding a purple juice, and the leaves of the flower have alſo ſome ſuch veins, and even the apices all contain a purple matter.

In the ſquare-ſtalked St. John's wort, commonly called St. Peter's wort, the edges of all the leaves, from the top to the bottom of the ſtalk, are ſurrounded with rows of theſe purple bags, and the apices of the flower are ſo many purple bags; but the cup and the petals of the flower have but very few purple veins in this ſpecies.

In the *hypericum pulchrum erectum*, or upright elegant St. John's wort, the leaves and ſtalks have no purple blebs, but only the cup and the flower have them. Theſe juices alone are what give the red colour to the oil of St. John's wort kept in the ſhops. And it is worthy a ſtrict enquiry, what they really are, and by what means produced.

Diverſe parts of the ſame *plant* yield different juices. The ſame veins, in their courſe through the different parts of the *plant*, yield juices of a different appearance. Thus the milky juice, in the root of the cow-parſnep, is of a brimſtone colour; but in the ſtalk it is white.

Among thoſe juices of vegetables which are clammy, and readily coagulate, there are ſome which readily break with a whey. The great wild lettuce, with the ſmell of opium, yields the greateſt plenty of milky juice of any known Engliſh *plant*. When the ſtalk is wounded with a knife, the juice flows readily out like a thick cream, and is white and ropy; but if theſe wounds be made at the top of the ſtalks, the juice that flows out of them is daſhed with a purple tinge, as if cream had been ſprinkled over it, with a few drops of red wine, and has ſome veins. Some little time after the letting this out, it becomes much more purple, and thickens, and finally the thicker part of it ſeparates, and the thin whey forms at the top. Herein the juice of this plant exactly reſembles the blood of animals, which, though a ſimple fluid, when drawn from the veſſel, yet ſoon ſeparates into a thick cake, and a thin fluid, or ſerum.

The whey, or thin part of this ſeparated matter, is eaſily preſſed out from the curd by ſqueezing between the fingers, and the curd then will remain white, and, on waſhing in fair water, becomes like rags. The purple whey, for in this part all the colour is lodged, ſoon dries into a cake of the ſame colour, and may be crumbled between the fingers into a purple powder. The white curd being dried, and kept ſome time, becomes hard and brittle. It breaks with a ſhining ſurface like reſin, and is inflammable, taking fire at a candle, and burning all away with a ſtrong flame. The ſame thick part being held over a gentle heat, would draw out into tough long threads, melting in the manner of wax.

The purple cake, made from the whey, is wholly different from this, and when held to a candle, ſcarce flames at all, but burns to a black coal. The whole virtue of the *plant* ſeems alſo to conſiſt in this thin part of its juice, for the coagulum or curd, though looking like wax or reſin, has no taſte at all, whereas the purple cake made from the ſerum is extremely bitter, and of a taſte ſomewhat reſembling that of opium.

It is poſſible that the artifice of bees may conſiſt, in a great meaſure, in the ſeparating in this manner the thick and the thin parts of the juices of peculiar *plants*, the curd or thick part of which, being glutinous and inſipid, may ſerve them as wax, and the thin part may make their honey.

The throat-wort, ſpurge, and many other *plants*, replete with milky juices, are of this kind, and their juice, when let out, ſeparates into curd and whey. But this, though a common law of nature, is not univerſal; for there are many *plants* which yield the like milky juices which do not ſeparate and break into curds and whey, but coagulate all together into one ſimple maſs. The white juice of the *ſanchus* never ſeparates, but dries into an uniform cake; the common red wild poppy bleeds freely with a milky juice, and the heads or capſules of ſeed bleed not leſs than the reſt of the *plant*, even after the flowers is fallen. This juice, on being received into a ſhell or other ſmall veſſel, ſoon changes its white to a deep yellow colour, and dries into a cake which ſeems reſinous and oily, but no whey ſeparates from it.

It ſeems by the experiments on the juice of the opium lettuce before mentioned, that theſe milky liquors are of a mixed kind, and compoſed of different fluids, of various and perhaps of contrary qualities; ſo that if the curd part be ſimple and harmleſs, the whey may be a powerful medicine, and ſo of the reſt; but in thoſe which do not ſeparate in this manner, we are forced to take the whole together, unleſs ſome way may be found of ſeparating them by art. Perhaps the ſetting them in wooden veſſels, and after a time adding freſh juice to them, may do it; and poſſibly the adding a little calf's rennet may be able to effect it.

The tragopogon, or goat's beard, when wounded, bleeds freely a milky juice; it is at firſt white, but becomes immediately yellow, and after that more and more red; at length it is wholly of a duſky red; it never ſeparates, but dries together into one cake, and is oily and reſinous, but of an inſipid taſte. The great bindweed bleeds freely alſo a white juice; the flowers, as well as the ſtalks and leaves, afford this liquor. It is of a ſharp taſte; and as many of the purging plants are of this claſs, it would be worth trying whether this milk be not purgative.

Theſe juices, as well as the generality of others which bleed freely from *plants*, are white like milk; but there are ſome of other colours. The juice of the great celandine is of a fine yellow; it flows from the *plant* in the

thickness of cream, and soon dries into a hard cake, without any whey separating from it. Another yellow juice is yielded by the seed-vessels of the yellow centaury, in the month of July, when the seeds are full grown. This is of a fine yellow colour, and very clammy; it soon hardens all together into a cake, no whey separating from it; it sticks to the fingers like birdlime, and is of the colour of pale amber, and will never become harder than soft wax, if dried in the shade; but if laid in the sun it immediately becomes hard like rosin. These cakes burn like wax, and emit a very pleasant smell. The great angelica also yields a yellowish juice on being wounded, and this will not harden at all, but if kept several years will still be soft and clammy, drawing out into threads like wax, or half melted resin.

Another kind of juices, very different from all these, are those of a gummy nature; some of these remain liquid a long time, and are not to be dried however without the assistance of heat; the others very quickly harden of themselves, and are not inflammable. The gum of the juice of rhubarb-leaves soon hardens, and is afterwards soluble in common water, and sparkles when put into the flame of a candle. These two qualities shew that these gums have a watery part in them, and they melt also in the flame of a candle, and become fluid like; and this shews that they have also the earthy part, though this does not separate from the whey in drying, as in some other cases. These do not sparkle in the flame so much as some others which contain more water; and their not kindling out into an actual flame, shews that they want oil. The clusters of the common honeysuckle are full of a liquid gum; they frequently throw this out, and it falls upon the leaves, and retains its own form there; the red hairs of the sun-dew are all terminated by large bladders of a thin watery fluid. This is also a liquid gum; it sticks to the fingers, and draws out into long threads; and this through the heat of the sun all day. In the centre of each of these dews drops, there is a small red bladder, which stands immediately on the summit of the red hair. This is of the nature of the blebs on the leaves and flowers of the St. John's wort, containing a purple juice which may be squeezed out of it. The pinguicula, or butter-wort, has also some gummy liquid matter on its leaves. It does not stand upon such long hairs as that of the sun-dew, but it is in much greater quantity. The hairs of the leaves of these two *plants* stand on the upper side of the leaves, and are very thick set there, while the under side is smooth. This is a singularity not observable in any other *plant*, at least of our own growth. Vide Lister, in Phil. Trans. N° 244. and Lowthorp's Abridg. vol. ii. p. 656, 657.

Mr. Boyle tells us, that the fumigated juices of *plants* may be successfully preserved by adding a small quantity of the white coagulum, made by the pure spirits of wine and urine. See OSTEA *alba*.

Some *plants* yield juices which are of a manifestly oily nature, which, being rubbed between the fingers, are not at all clammy, but make them glib and slippery; and these juices do not harden at all on being exposed to the air. If the flark of elecampane be wounded, there flows out a plain oily juice swimming upon a watery one. The stalks of hemlock also afford the same oily liquor swimming upon the other; and the common white mullein, if the leaves are pulled off in the month of June, yields the same sort of oil very freely along with its watery juice. The berries of ivy, the bay, juniper, dog-berry-tree, and the fruit of the olive, when wounded, shew their oil in the same manner floating on the watery juice.

Some of these oily juices, soon after they are let out of the *plant*, coagulate and harden into a kind of resin. Our ivy yields such a juice very abundantly, and the juice of the small purple-berried juniper is of the same kind, being hard and fat, and not very gummy.

If the bark of the common ivy be wounded in March, there will come out a tough and greasy matter of a yellowish colour; if this be taken up between the fingers, it feels not at all gummy or sticking, but melts in handling into a sort of oil, which in process of time hardens and crusts upon the wounds, and looks like brown sugar; it burns with a lasting flame, and smells very strong. The tops of the wild lettuce, and the leaves growing near the tops, if examined with a magnifying-glass, shew a great number of small bladders or drops of an oily juice of a brownish colour, hardening into a kind of resin; they are easily wiped off when of any size, and are truly an oily juice hardened a little. It is probable also, that the fine blue flower or powder called the bloom, upon the surface of our common *plums*, is no other than such an oily juice exudating from their pores in small particles, and hardening into a sort of resin. The leaves and stalks of the common English mercury are all over covered with small transparent drops looking like pearls; and if the *plant* is taken into the hand, these feel rigid and greasy. The leaves of the stinking orach abound also with the same sort of drops, and these are only small portions of the oily juices of the *plant*, which are continually exsudating through its pores, and harden into these resiny pearls. Phil. Trans. N° 224.

The sap or juice of trees appears to be very different, according to the species or genus of the tree, as we find by experiments, or by their spontaneous exudations. The extravasations of sap in the plum and cherry-kind, being all clammy, and hardening into a gum like gum arabic; and, on the other hand, those of the vine, the oak, and many other trees, being thin as water. The clamminess of the sap in trees seems one of the great things that renders them hardy, and not liable to injuries from cold, &c. In the hard frosts, those trees which have watery juices perish, and even split and cleave of themselves; while those which have gummy and viscous juices escape. In our gardens the vines crack and split with the frost, while the plums, cherries, peaches, and other gummy trees, stand without any damage or danger; and in the fields no trees so readily split in severe frosts as the oaks, which though the hardest wood of all our timber-trees, yet have of all the most thin and watery juices. The trees which have deciduous leaves, have in general thinner and more watery juices than the evergreens; so the freezing of these, or their decay from want of due heat, and other accidents, is owing the decay and fall of these leaves, while the others remain in their places, though not increasing, or no new ones growing, the juices remaining unaffected, though stagnated in the vessels, and safe from injury, though waiting the sun's heat to put them in motion. The earlier or later germination of trees and *plants* of different kinds, is probably owing also to the same cause. The thinnest juices, as they are soonest injured by cold, so they are probably soonest influenced also by heat; and that warmth may make them move, and prepare the *plant* for growing, which could scarce begin to attenuate the tough and gummy ones. Phil. Trans. N° 165.

PLANT'S, *salts of*. It has been observed by all who have examined the different essential *salts of plants*, that some of them, when thrown on the fire, have the crackle of sal-petre, and others of common sea-salt; and it has been concluded from hence, that they really contained particles of those salts, which their roots had taken in with their nourishment, and conveyed up into the stalk and leaves with the juices; and that these salts still retained their original nature, and were no otherwise altered than by the mixture with other substances in the *plant*. But as two *plants* of different qualities, when set in the same earth closely by one another, shall out of the same juices make a medicine, a salad, or a poison, it cannot be, but that the substances abiding by the root, be they what they will, must be greatly altered in the *plant*; insomuch, that a salt purely nitrous, when received into the root, might become of the nature of sea-salt, or of the volatile urinous kind, according to the different organs of the *plants*, and the different natural fermentations it might meet with there. To be perfectly informed of this, Mr. Homberg made the following experiment:

He took a large quantity of rich black garden mould, and washed it in several waters, to carry off all the salts it might contain: this done, he divided the earth into four boxes or cases of wood, into each of which there was put about two hundred weight. Two of these cases of earth he watered with a solution of sal-petre, so as to make each imbibe about two ounces of that salt; the other two cases were left with the earth insipid as the washing had made it, and care taken to water them with none but perfectly pure water, so that they might remain as simple as possible. In one of the cases of nitrous earth, and in one of those of simple earth, he sowed fennel, and in the other two, garden cresses.

The herbs in all the cases grew very well, and when they were grown to about eight inches high, they were all gathered, and when the roots were cleared, and the whole product weighed, those *plants* which had grown on the simple earth weighed twenty-five ounces, and those in the nitrous earth twenty-six; their smell and taste manifested no sort of difference in either. In order to examine these *plants*, while yet quite fresh, by means of fire, he put a pound and a half of each, with their roots, into a retort of glass: he placed these retorts first in a balneum Mariæ, and then in a sand-heat, in order to drive over all the aqueous humidity. The quantity of water from each retort was within a few grains of the same weight; and from the beginning to the end of the distillation there was not the least appearance of any acid.

After this, the cresses which had grown in the insipid

earth yielded a drachm of volatile salt; and that which had grown in the earth which had imbibed salt-petre, yielded seventy-five grains.

The oil of each was very nearly the same in quantity; that from the plants in the salt-petre earth weighing six grains more than that of the *plants* of the insipid earth. The lixivial oil was two drachms from the *plants* in the nitrous earth, and one drachm and sixty-seven grains from those in the insipid.

The differences between these two parcels of *plants* upon the analysis, appeared on the whole so little, that it could not be counted any thing; since the more or less chemistration of the vessels, or many other accidents in the distilling, might have easily occasioned as much in *plants* perfectly the same in all respects. If there be any thing, however, to be collected from the experiment, it is, that the earth impregnated with a solution of nitre, yielded more of the principles than the other; probably from its actually affording a quantity of oil to the juices of the *plants* in the growth: but as the nitrous earth afforded a *plant* which yielded more oil than that from an insipid soil, it will be from this that the portions of the earth not being able to carry off any of the fatty parts, they remained in the same quantity in both; but that the nitre, where it was, had contributed somewhat to the breaking of them, and the rendering them more fit to be absorbed by the *plants*. From the different weights of the *plants* when gathered, after the time of growth, from the same seed, and with all the same advantages in common, it may be concluded, that the nitrous salts in the earth are not essentially necessary to vegetation, since the *plants* in the insipid earth grew very well without them; yet that they are very useful, since the *plants* produced there were of a greater bulk, and according to the whole analysis, if the differences are to be depended on as resulting wholly from the nature of the subjects, they yielded more of all the active principles; and therefore, that they were to all purposes better *plants*. *Mem. Acad. Par.* 1693.

The weights above mentioned are French, the word *gros* being translated drachm, though really exceeding it by twelve grains. See WEIGHT.

PLANTS, *fossile*. Many species of reedlet and herbaceous *plants* are found at this day, in great abundance, buried at considerable depths in the earth, and converted, as it were, into the nature of the matter they lie among; fossile wood is often found very little altered, and often impregnated with substances of almost all the different fossile kinds, and lodged in all the several strata, sometimes firmly embedded in hard matter; sometimes loose: but this is by no means the case with the tenderer and more delicate subjects of the vegetable world. These are usually immersed either in a shockish clay substance, found lying over the strata of coal, or else in loose nodules of ferruginous matter of a pebble-like form, and they are always altered into the nature of the substance they lie among: what we meet with of these are principally of the fern kind; and what is very singular, though a very certain truth, is, that these are principally the forms of American growth, not those of our own climate.

The most frequent *fossile plants* are the polypody, spleenwort, ofmund, trichomanes, and the several larger and smaller ferns; but beside these there are also found pieces of the equisetums, or horse-tails, and joints of the reed-like *plants*, as the rivers, rudder, and the like; and these have been too often mistaken for flowers; sometimes there are also found complete grasses, or parts of them, as also reeds and other watery *plants*; sometimes the ears of corn, and not unfrequently the rinds or bark, and impressions of the bark, and fruit of the pine or fir kind, which have been, from their scaly appearance, mistaken for the skins of fishes; and sometimes, but that very rarely, we meet with moffes and sea-*plants*.

Many of the ferns not unfrequently found, are of very singular kinds, and some species yet unknown to us; and the leaves of some appear set at regular distances, with round protuberances and cavities. The stones which contain these *plants* split readily, and are often found to contain, on one side, the impression of the *plant*; and on the other the prominent *plant* itself: and, beside all that have been mentioned, there have been frequently supposed to have been found with us ears of common wheat, and of the maiz or Indian corn; the first being in reality no other than the common endmoft branches of the fir, and the other the thicker boughs of various species of that and of the pine kind, with their leaves fallen off; fuch branches in fuch a ftate cannot but afford many irregular tubercles and papillæ, and, in fome fpecies, fuch as are more regularly difpofed.

Thefe are the kinds moft obvious in England; and thefe are either immerfed in the flaty ftone which conftitutes whole ftrata, or in ftatted nodules, ufually of about three inches broad, which readily fplit into two pieces on being ftruck.

They are moft common in Kent, on coal-pits, near Newcaftle, and the foreft of Dean, in Gloucefterfhire; but are more or lefs found about almoft all our coal-pits, and many of our iron mines. See *Tab. of Foffils, claſs* 6.

Though thefe feem the only fpecies of *plants* found with us, yet in Germany there are many others, and thofe found in different fubftances. A whitifh ftone, a little harder than chalk, frequently contains them: they are found alfo often in a grey flaty ftone, of a firmer texture, not unfrequently in a blackifh one, and at times in many others: nor are the bodies themfelves lefs various here than the matter in which they are contained: the leaves of trees are found in great abundance, among which thofe of the willow, poplar, whitethorn, and pear-tree, are the moft common; fmall branches of firs, leaves of the olive-tree, and ftalks of garden ſtuffe, are alſo found there; and fometimes ears of the various fpecies of corn, and the largeſt as well as the fmalleſt moſſes in great abundance.

Thefe feem the tender vegetables, or herbaceous *plants*, certainly found thus immerfed in hard ſtone, and buried at great depths in the earth; others of many kinds there are alſo named by authors, but, as in bodies fo imperfect, errors are eaſily fallen into, theſe ſeem all that can be aſcertained beyond mere conjecture. Hill's Hiſt. of Foſſils, p. 64.

PLANT, *burning thorny*. See SPURGE.

PLANT, *egg*, a ſpecies of *ſolanum*, or NIGHTSHADE.

PLANT, *ice*. See ICE.

PLANTS, *marine*. See SEA-*plants*.

PLANT, *parafitical*. See PARASITE.

PLANT-*root*, a term uſed by Dr. Grew, to expreſs the radicle in ſeeds; he by this name diſtinguiſhes it from what he calls the SEMINAL *root*; which is a very different ſubſtance diſtributed throughout the parenchyma of the ſeed, but wholly different from it, and preying upon it as the *plant-root* does upon the earth.

PLANT, *ſenſitive*, is the Engliſh name of a diſtinct genus of *plants*, called by the botaniſts *mimoſa*. See SENSITIVE *plant*.

PLANT, *laſting & fruitleſs*. See ACHRONOMENE.

PLANTA, in *Anatomy*, the loweſt part, or ſole of the FOOT of a man, comprehended between the tarſus and the toes.

PLANTAGENET, in *Hiſtory*, an addition, or ſurname, borne by many of our ancient kings.

The term *Plantagenet* has given infinite perplexity to the critics and antiquaries, who could never fettle its origin and etymology.

It is allowed, that it firſt belonged to the houſe of Anjou and was brought to the throne of England by Henry II. where his male poſterity preſerved it till the time of Henry VI. a ſpace of above four hundred years.

It is diſputed, who it was that firſt bore the name. Moſt of our Engliſh authors conclude, that our Henry II. inherited it from his father Geoffrey V. earl of Anjou, ſon of Fulk V. king of Jeruſalem, who died in 1144. This Geoffrey they will have the firſt of the name; and not Henry II. the iſſue of Geoffrey, by Maud, only daughter of Henry I. the ſecond.

Yet Mainge will not allow Geoffrey to have borne the name; and adds, that, in effect, the old annaliſt of Anjou, J. Bourdigne, never calls him ſo. The firſt, Mainge adds, to whom he gives the appellation, is Geoffrey, third ſon of this Geoffrey V.

Yet moſt the name be much more ancient than either of theſe princes, if what Skinner ſays of its origin and etymology be true. That author tells us, that the houſe of Anjou derived the name from a prince thereof, who, having killed his brother to enjoy his principality, took to repentance, and made a voyage to the Holy Land, to expiate his crime; diſciplining himſelf every night with a rod made of the plant genet, genilla, broom; whence he became nicknamed *Planta-genet*.

Now it is certain, that our Geoffrey made the tour of Jeruſalem; but then he did not kill his brother, nor did he go thither out of penance, but to aſſiſt king Amaurin his brother. Who then ſhould this prince of the houſe of Anjou be? Was it Fulk IV? It is true he diſpoſſeſſed his elder brother Geoffrey, and put him in priſon; but he did not kill him: nay, Bourdigne obſerves, he was even releaſed out of the ſame by his ſon Geoffrey V. already mentioned.

Father; this Fulk did make a journey to Jeruſalem; and that, too, partly out of a penitential view: we are aſſured, by Bourdigne, he did it out of apprehenſion of the judgments of God, and eternal damnation, for the great effuſion of Chriſtian blood in the many mortal battles he had been in. The annaliſt alſo adds, that he made a ſecond voyage; but it was to return God thanks for his mercies, &c. to which we may add, that Fulk was never called *Plantagenet*; ſo that what Skinner advances, appears to be a fable.

There

There is another common opinion, which appears no better founded; and it is this: that the name *Plantagenet* was common to all the princes of the house of Anjou, after Geoffrey V. whereas, in fact, the name was only given to a few; and that, as it should seem, to distinguish them from the rest. Thus Bourdigne never applies it to any but the third son of Geoffrey V. and distinguishes him, by this appellation, from the other princes of the same family. Though it is certain that it was likewise given to the elder brother, Henry of England, as before observed.

PLANTAGINELLA, in *Botany*, a name given by Dillenius to a genus of plants since called by Linnæus LIMOSELLA.

PLANTAGO, in *Botany*. See PLANTAIN.

PLANTAIN, *plantago*, in *Botany*, the name of a genus of plants, the characters of which are these: the empalement is quadrifid; the flower consists of one leaf, of the *tetrandria monogynia* class; and is wide, expanded at the opening, and with a reflex limb, and usually divided into four segments; from the bottom of this flower rises a pistil surrounded with stamina of considerable length; the fruit is a capsule, which when ripe separates transversely into two pieces, and is divided by an intermediate septum into two cells, filled with oblong seeds.

The species of *plantain*, enumerated by Linnæus are twenty-one, comprehending, besides the several species of *plantains*, usually so called, the psyllium, or fleawort, and the coronopus or buckhorn.

The *plantains* grow naturally in pastures in most parts of England, and are frequently very troublesome weeds. The common broad-leaved *plantain*, and the narrow-leaved or ribwort are used in medicine; they possess much the same qualities, though the first has been generally directed for medicinal use in preference to the other. The leaves and seeds, recommended as vulneraries, in phthisical complaints, spittings of blood, alvine fluxes, &c. appear to be of the milder kind of restringents or corroborants. The expressed juice of the leaves, depurated by settling and colature, or clarified with white of eggs, and inspissated to the consistence of honey, and called the extract of *plantain*, manifests a considerable saline austerity. The leaves are, in some places, the usual application made by the common people to slight wounds.

Of the buckhorn *plantain* there are two varieties growing in England, one of which is plentiful every where on heaths, and was formerly cultivated in gardens as a salad herb, and the other is the narrow-leaved Welsh sort, which is found on many of the Welsh mountains.

The seeds of the *psyllium*, or FLEA-*wort*, have been usually brought from the south of France. The mucilage which they yield has been chiefly employed in emollient glysters, in gargarisms for hoarseness and asperity of the fauces, and in external applications for chaps of the lips, and inflammations of the eyes. Prosper Alpinus relates, that, among the Egyptians, the mucilage, or an infusion of the seeds, is given internally in ardent fevers, and that it generally either loosens the belly or promotes sweat. Lewis.

PLANTAIN, *water*, *alisma*, in *Botany*, a genus of the *hexandria polygynia* class and order: its characters are, that the empalement is composed of three leaves, that the flower has three petals, and that the seeds are numerous. Linnæus enumerates seven species.

PLANTAIN, *lesser water*. See LIMOSELLA.

PLANTAIN *shot*. See CANNA.

PLANTAIN, *star-headed water*, *damasonium*, in the Linnæan system of *Botany*, is a species of the *alisma*, or *water*-PLANTAIN: but Mr. Miller has made it a distinct genus with the following characters: it hath a flower composed of three leaves, which are placed orbicularly, and expand in form of a rose; out of the flower-cup arises the pistil, which afterward becomes a star-shaped fruit, with many cells, which are full of oblong seeds. He reckons two species.

PLANTAIN-*tree*, *musa*, in *Botany*, a genus of the *polygamia monœcia* class. Its characters are these: it hath male and female flowers upon the same stalk, several of which are hermaphrodite; these are produced on a single stalk, or spadix; the male flowers are situated on the upper part of the spike, and the female below; these are in bunches, each bunch having a sheath or cover, which falls off; the flowers are of the lip kind; the two petals constitute the upper lip, which is erect, and furnished with five horizontal points, and the nectarium, which is concave and shorter; they have six stamens, five of which are perfect; the germen is situated under the flower, which is long, having three obtuse angles, supporting an erect cylindrical style, crowned by a roundish stigma; the germen afterwards turns to an oblong, three-cornered, fleshy fruit or berry, covered with a thick rind, divided into three parts.

Here we may observe, that the *musa paradisiaca*, or *plantain-tree*, produces a spadix, which contains often two hundred germina, the few female flowers of which continue in blow for some days; when the female flowers have done blowing, the males succeed, and continue in flower till the fruit is ripe, in which are to be found no seed at all. Wherefore the authors of the Hortus Malabaricus have asserted that seeds were evidently wanting, in the *plantain-tree*, and this seemed a paradox to Linnæus; but when he saw the first female flowers destitute of males, and that the males which followed came too late to impregnate the females, he clearly perceived that no seeds would ever be produced in this species, unless several plants placed together were to flower nearly at the same time, and then one could impregnate the other. There is one thing farther remarkable in the *musa*, viz. that it produces two sorts of flowers very different in the same plant, some of which want the stigmata, and others the antheræ; the first may be called male hermaphrodites, and the latter female hermaphrodites. So that here we have a peculiar kind of polygamy, where those different flowers may impregnate each other, and one female joined with barren males is impregnated by the males belonging to another female, which is itself barren. See *Generation of* PLANTS.

Of this genus Miller reckons two, and Linnæus four species.

The first sort, or *musa* with a nodding spike, and a long three-cornered fruit, is cultivated in all the islands in the West Indies, where the fruit, which is roasted in the embers, serves the negroes for bread; and some of the white people also prefer it to most other things, especially to the yams and cassada bread. This plant rises with a soft herbaceous stalk fifteen or twenty feet high; the lower part is often as large as a man's thigh, diminishing gradually to the top, where the leaves come out on every side.

The fruit is eight or nine inches long, and above an inch diameter; the skin is tough, and within is a soft pulp of a luscious sweet flavour; the spikes of fruit are often so large as to weigh upward of forty pounds. The leaves are used for napkins and table-cloths, and are food for hogs.

The second sort, with a nodding spike, and a cucumber shaped fruit, which is commonly called BANANA, differs from the former, in having its stalks marked with dark purple stripes and spots; the fruit is shorter, straighter, and rounder; the pulp is softer, and of a more luscious taste, so is generally eaten by way of desert, and seldom used in the same way with the former; therefore is not cultivated in such plenty.

It grows in both the Indies, and the fruit is used, which is very nourishing, provokes urine, and stimulates to venery.

PLANTANOCEPHALUS, in *Botany*. See BUTTON-*tree*.

PLANTARIS, in *Anatomy*, a muscle which has a fleshy beginning from the back-part of the external protuberance of the thigh-bone, and, descending a little way between the gemellus and soleus, becomes a long and slender tendon; which proceeds, by the inside of the great tendon over the os calcis to the bottom of the foot, and expands itself, under the sole, upon the musculus perforatus, to which it adheres closely, as the palmaris does to the hand. See *Tab. Anat. (Myol.) fig.* t. *n.* 68.

Some reckon this among the extenders of the foot. See EXTENSOR.

PLANTATION, in the *Islands and Continent of America*, a spot of ground which some planter, or person arrived in a new colony, cultivates and tills for his own use.

Plantations, or colonies in distant countries, are either such where the lands are claimed by right of occupancy only, by finding them desart and uncultivated, and peopling them from the mother country; or where, when already cultivated, they have been either gained by conquest, or ceded to us by treaties. See COLONY.

But there is a difference between these two species of colonies, with respect to the laws by which they are bound. For it hath been held (Salk. 411, 666), that if an uninhabited country be discovered and planted by English subjects, all the English laws then in being, which are the birth-right of every subject, are immediately there in force. But this must be understood with very many and very great restrictions. Such colonists carry with them only so much of the English law, as is applicable to their own situation and the condition of an infant colony; such, for instance, as the general rules of inheritance, and of protection from personal injuries. But in conquered or ceded countries, that have already laws of their own, the king may indeed alter and change those laws; but, till he actually does change them, the ancient laws of the country remain, unless such as are against the

law of God, as in the case of an infidel country. 7 Rep. 17. Calvin's case. Show. Parl. cap. 31.

Our American *plantations* are principally of this latter sort, being obtained in the last century either by right of conquest and driving out the natives, or by treaties. And, therefore, the common law of England, as such, has no allowance or authority there; they being no part of the mother country, but distinct, though till the late unhappy contest, dependent dominions. They, says Judge Blackstone, are subject, however, to the controul of the parliament: whilst, on the other hand, it is as strenuously contended, that they neither are nor can be subject to the legislative authority of the parliament of Great Britain. But the litigation and decision of this question has been unfortunately referred to the issue of a war, the wished for termination of which may produce alterations in the state of our American *plantations*, and their connection with this country, which render it impossible now (1782) to say, how their government may be conducted for the future.

Previous to our late contest, our colonies, with respect to their interior polity, were of three sorts: viz. Provincial establishments, proprietary governments, and charter-governments. See CHARTER-*governments*.

PLANTATIONS and *Trade, board of*. See BOARD.

PLANTE-*ver*, in *Natural History*, the name of a herb sent over from China, where it is called *hoiffatzaotcheom*; that is to say, a plant which at a certain time of the year changes into a worm. The Chinese say, that this is a plant during the summer season; but that in winter its stalk dies, and the root becomes a worm. Mr. Reaumur has well observed, that in the present improved state of natural knowledge, we can give no credit to such marvellous accounts; and of the roots sent over to the Academy at Paris, it appeared, that only a certain part of each was to undergo this change: this, however, if true, was no less a marvel than that the whole should.

Father Parenin, who sent it to France, observes, in his account of it, that it was a very scarce plant even in China; being found only at the palace of Pekin there, where also it was not native, but brought from the mountains of Tibet, and some other places on the confines of the Chinese dominions. This father had never seen the leaves or flowers of the plant, but only its roots, which were in high esteem there, not only because of their miraculous changes, but from their possessing the virtues of the famous ginseng; but with this advantage, that the use of them was not subject to be attended with those hæmorrhages which frequently affected the persons who take large quantities of that famous root. The roots of this *plante-ver* are usually about a quarter of an inch thick, and from an inch to three inches in length; but there are much larger in the places where they grow.

These roots had nothing particular in their figure or appearance; but with these the father sent some of those which were supposed to be changed into worms, concerning which he observed, that nothing could more exactly express a worm or caterpillar; the head, the eyes, the feet, and the mouth, being all plainly distinguishable, as well as the several folds and cuttings-in of the body. This account was found to be perfectly true; but the mistake was the want of proper accuracy in the observation; for this body, which was supposed to be the root transformed, had in reality never been any part of the plant, but was found to be really and truly a caterpillar.

This was one of the under-ground kind, or at least of those which go into the ground to pass their transformation: of these we have a great many different species in all parts of Europe, and some of them, when they are entering into their nymph state, have a custom of fastening themselves to the roots of plants. Of this kind was the Chinese insect, which, when the time of its change approached, always selected the roots of this plant as of a proper size and dimension for its purpose; and, gnawing off the end, hollowed away the stump, so as to introduce its tail into the cavity; where it remains covered with the bark of the root, which so nicely joins to it, that people who observe it in a slight way cannot but mistake it to be a part of the root, or the remainder of the root a continuation of its body. The more accurate naturalists will, however, easily distinguish the vegetable fibres, which make up the root from the animal ones of the caterpillar; and to an eye accustomed to such researches, the nice joining of the tail to the remainder of the root will easily discover itself. Mem. Acad. Par. 1720.

PLANTED *coat*, in the *Manege*. See HAIR.

PLANTING, in *Agriculture* and *Gardening*, the setting of a tree, or plant, taken up from its former place, in a new hole or pit, proportionable to its bulk, throwing fresh earth over its root, and filling up the hole to the level of the other ground.

As PLANTATIONS of trees are not only profitable to the owner, as well as ornamental to the country around them, but a national advantage, it may not be improper to give some general directions concerning them; referring to the several articles for more particular instructions.

First, then, care must be taken to prepare the ground before trees are taken out of the earth; because they should never be suffered to remain long out of the ground. Care likewise is to be taken not to tear or bruise the roots of the trees, in raising them in order to be transplanted. When taken up, the next thing to be done is to prepare them for *planting*; which is done by cutting off all the small fibres of the roots, and such roots as are any wise injured in pulling up, or which cross one another. The downright roots of fruit trees are likewise to be pruned off, as should all their irregular branches; that when agitated by the wind, they may not rub against or bruise each other. However, the main shoots ought by no means to be cut off, as is but too often injudiciously practised.

Having thus prepared the trees for *planting*, they are next to be fixed in the ground; in doing which, if they have been long out of the ground, their roots should be previously immersed in water for eight or ten hours; and care must be taken to place them deeper or shallower, according to the nature of the soil; in which, if it be cold and moist they should be planted very shallow: but if it be a hard rock or gravel, the best method of all is to raise a hill of earth, wherein to plant them. They should be placed as erect as may be, with the roots as deep in the ground as they were growing before they were taken up, and the earth gently pressed down about their roots; for it is a fault to make it too hard. Poles or stakes should be fixed round those that are standards, in order to prevent their being displaced or blown down by the wind.

When the trees are thus *planted* and secured, a little mulch should be laid upon the surface of the ground, to prevent its drying; and as to watering them, it ought to be done with great moderation, nothing being more hurtful to them than over-watering.

The seasons for *planting* are various, according to the different sorts of trees, or the soil in which they are to be planted.

For such trees whose leaves fall off in winter, the best time is the beginning of October, provided the soil be dry; but for a wet soil, it is better to defer it to the latter end of February, or the beginning of March; and for many kinds of ever-greens, the beginning of April is by far the best season; though some sorts may be safely removed at Midsummer, provided they are not to be carried far. They should always be removed in a cloudy moist season, by which means they will take root in a few days.

As the method of cultivating most trees, especially garden ones, is explained under their respective articles, there is the less reason to be particular on that head in this place. However, one thing more deserves to be well attended to, as regarding plantations in general. It is this; that plantations of fruit and other trees should be raised always from trees transplanted from nurseries, and never from hedge-rows, or trees of a large size, because these last seldom come to good account, often dying after continuing alive for many years.

Another general rule in regard to plantations, is, to keep the ground clear of weeds, at least for the space of seven years; for which purpose it should be annually dug or plowed, where that can be done. This will encourage the roots of the trees to extend themselves, whereby they will draw a larger proportion of nourishment. Miller's Gard. Dict.

PLANTING *an orchard*. See ORCHARD.

PLANTING *of forest trees*. See SEMINARY, NURSERY, TIMBER, and TREE. See also ASH, CHESTNUT, ELM, OAK, &c.

PLANTING *of wall fruit-trees*. After two years growth in the nursery, stone-fruit, being first inoculated or grafted, are ready for removal; which is best done in October or November.

To prepare the soil for its new guest, a hole is dug two feet deep; or, if the soil be not very good, the pit is made shallower, and the earth raised above it. With the soil dug up, they frequently mix either a rich soil from elsewhere, or manure, so as the mixed be at least as rich as the soil out of which the tree came. The hole being half filled up with this compost, it is trodden down, to afford a firm rest to the root; all the extremities whereof are cut off, and the tree fitted to the wall, by cutting off such branches as grow directly either towards or from the wall, and leaving only the side-branches, which are to be nailed to it.

This done, the tree is set in its hole, as far from the wall

as is consistent with the head's spreading thereon, that the root may have the more room backwards; and the hole is then filled up with the compost.

If the soil be poor, it is proper to manure round the tree; and, at the end of February, to cover it with fern, or straw. It will also be necessary to prune and nail the tree to the wall, at least twice or thrice every year.

PLANTING, *inverted*, or *reverse*, is a method of *planting* wherein the ordinary position of the plant, or shoot, is inverted; the branches being set in the earth, and the roots reared into the air.

Agricola mentions this monstrous way of *planting*, which, he assures us, succeeds very well in most, or all sorts of fruit-trees, timber-trees, &c. both foreign and domestic. Bradley affirms to have seen a lime-tree, in Holland, growing with its first roots in the air, which had shot out branches in great plenty, at the same time that its first branches were turned into roots, and fed the tree.

The industrious Mr. Fairchild has practised the same with us, and gives us the following directions for the performance thereof.

Chuse a young tree of one shoot, of alder, elm, willow, or any other tree that takes root readily by laying; bend the shoot gently down, till the extreme part be in the earth, and so let it remain till it has taken good root. This done, dig about the first root, and gently take it up out of the ground, and raise it till the stem be nearly upright; in which state stake it up.

Then prune the roots, now erected in the air, from the bruises and wounds they received in being dug up; and anoint the pruned parts with a composition of four parts of bees-wax, four of tallow, two of resin, and two of turpentine, melted together, and applied pretty warm. Then prune off all the buds or shoots upon the stem, and dress the wounds with the same composition, to prevent any collateral shootings; and leave the rest to nature.

PLASTING, in *Architecture*, denotes the laying the first courses of stone on the foundation, according to the measures, with all the exactness possible.

PLASHING, a term used by our farmers to express an operation performed at certain times upon their quick-set-hedges, in order to assist their growth and continuance.

This operation is performed sometimes in October, but more usually in February; and this is by much the better season for it. Suppose a hedge to be of twenty or thirty years growth, and full of old stubs as well as young shoots: this is the kind of hedge that requires *plashing* most of all.

The old stubs must be cut off within two or three inches of the ground, and the best and longest of the middle-sized shoots must be left to lay down. Some of the strongest of these must be left to answer the purposes of stakes. These are to be cut off to the height at which the hedge is intended to be left; and they are to stand at ten feet distance one from another: when there are not proper shoots for these at the due distances, their places must be supplied with common stakes of dead wood. The hedge is to be first thinned, by cutting away all but those shoots which are intended to be used either as stakes, or the other work of the *plashing*: the ditch is to be cleaned out with the spade: the ditch must be now dug as at first, with sloping sides each way; and when there is any cavity on the bank on which the hedge grows, or the earth has been washed away from the roots of the shrubs, it is to be made good by facing it, as they express it, with the mould dug from the upper part of the ditch; all the rest of the earth dug out of the ditch is to be laid upon the top of the bank, and the owner should look carefully into it that this be done; for the workmen, to spare themselves trouble, are apt to throw as much as they can upon the face of the bank; which, being by this means overloaded, is soon washed off into the ditch again, and a very great part of the work undone again, whereas what is laid on the top of the bank always remains there, and makes a good fence of an indifferent hedge.

In the *plashing* the quick, two extremes are to be avoided; these are, the laying it too low, and the laying it too thick: this makes the sap run all into the shoots, and leaves the *plashes* without sufficient nourishment into the *plashes*, and so makes the shoots small and weak at the bottom, and, consequently, the hedge thin. This is a common error in the north of England. The best hedges made any where in England, are those of Hertfordshire; and they are *plashed* in the middle way between the two extremes, and the cattle are by that prevented both from cropping the young shoots, and from going through; and a new and vigorous hedge soon forms itself.

When the shoot is bent down that is intended to be *plashed*, it must be cut half way through with the bill; the cut must be given sloping, somewhat downwards, and then it is to be wound about the stakes, and after this its superfluous branches are to be cut off, as they stand out at the sides of the hedge. If for the first year or two the field where a new hedge is made can be plowed, it will thrive the better for it; but if the stubs are very old, it is best to cut them quite down, and to secure them with good dead hedges on both sides, till the shoots are grown up from them strong enough to *plash*; and wherever void spaces are seen, new sets are to be planted to fill them up. A new hedge raised from sets in the common way, generally requires *plashing* about eight or nine years after. Mortimer's Husbandry, p. 10.

PLASM, PLASMA, is sometimes used for a MOULD, wherein any metal, or such like running matter, which will afterwards harden, is cast, to receive its figure.

PLASTER, or PLASTER, in *Building*, a composition of lime, sometimes with hair, sometimes with sand, &c. to parget or cover the nudities of a building.

There is also a *plaster* of a coarser sort than the PLASTER of Paris, which is sometimes used in this country for floors in gentlemen's houses, and for corn-granaries: it is made of a bluish stone, taken out of quarries, which are generally at the side of a hill, much like the stone of which Dutch terrafs is made: the stone is burnt like lime, becomes white by burning, and when mixed with water does not ferment like lime: when cold, it is beat into a fine powder, and when it is used, the quantity of about a bushel is put into a tub and water applied to it, till it becomes liquid: in this state it is well stirred with a stick, and used immediately; for in less than a quarter of an hour it becomes hard and good for nothing, as it will not bear being mixed a second time like lime. See GYPSUM, and PLASTERING.

PLASTER, in *Pharmacy*, an external application of a harder consistence than our ointments: these are to be spread according to the different circumstances of the wound, place, or patient, either upon linen or leather.

If the part upon which they are to be laid be naturally hairy, it must be shaved; but that they may stick the better, the natural shape of the part must be consulted, and the *plaster* spread and formed accordingly, either round, square, triangular, elliptical, in a lunar form, or in shape of the letter T. Some also are divided at both ends, and others are perforated in the middle; those last are of frequent use in fractures attended with a wound: for by this contrivance the wound may be cleansed and dressed without removing the *plaster*.

Indeed there is almost no part of the body which a *plaster* of one of those forms may not be made to serve for, if it be notched about the edges with a pair of scissars. See EMPLASTER.

The use of *plasters* are various; they are serviceable in securing the dressings, they also forward the maturation of the pus, agglutinate and heal wounds, unite broken bones, heal burns, assuage pain, and strengthen weak parts. Heister.

The calces of lead boiled with oils unite with them into a *plaster* of a proper consistence, which makes the basis of several other *plasters*: in boiling these compositions, a quantity of hot water must be added from time to time, to prevent the *plaster* from burning and growing black; but this should be done with care, lest it cause the matter to explode.

PLASTERS, *adhesive*, *anodyne*, *blistering*, *common*, *drawing*, *gum*, *mercurial*, *plumbeo*, and *strengthening*. See EMPLASTRUM.

PLASTER, *warm*, is made by melting together over a gentle fire, one ounce of gum *plaster*, and two drachms of blistering *plaster*. This is useful in the sciatica, and other fixed pains of the rheumatic kind; it ought, however, to be worn for some time, and to be renewed, at least, once a week.

PLASTER, *wax*, is formed by melting together one pound of yellow wax, half a pound of white resin, and three-quarters of a pound of mutton fat. This is generally used instead of the MELILOT *plaster*, and is a proper application after blisters, and in other cases where a gentle digestion is necessary.

PLASTER *of Paris* is a fissile stone, serving many purposes in building; and used likewise, in sculpture, to mould and make statues, basso relievos, and other decorations in architecture.

It is dug out of quarries, in several parts of the neighbourhood of Paris; whence its name. The finest is that of Montmartre.

Plaster of Paris, among our workmen, is of two kinds, viz. *crude*, or in the stone, and *burnt*, or beaten.

The *crude* is the native *plaster*, as it comes out of the quarry; in which state it is used as shards in the foundations of buildings.

The *burnt plaster* is a preparation of the former, by calcining

cining it like lime in a kiln or furnace, and then beating it into powder, and diluting and working it. In this ſtate it is uſed as mortar, or cement, in building.

This, when well ſifted, and reduced into an impalpable powder, is alſo uſed to make figures, and other works of ſculpture; and is, beſides, of ſome uſe in taking out ſpots of greaſe, &c. in ſtuffs and ſilks.

In the *plaſter* quarries is alſo found a kind of falſe talc, or plated ſelenites, wherewith they counterfeit all kinds of marble. See GYPSUM.

The method of repreſenting a face truly in *plaſter of Paris*, is this: the perſon whoſe figure is deſigned is laid on his back, with any convenient thing to keep off the hair. Into each noſtril is conveyed a conical piece of ſtiff paper, open at both ends, to allow of reſpiration. Theſe tubes being anointed with oil, are ſupported by the hand of an aſſiſtant; then the face is lightly oiled over, and the eyes being kept ſhut, alabaſter freſh calcined, and tempered to a thinniſh conſiſtence with water, is by ſpoonfuls nimbly thrown all over the face, till it lies near the thickneſs of an inch. This matter grows ſenſibly hot, and in about a quarter of an hour hardens into a kind of ſtony concretion; which being gently taken off repreſents, on its concave ſurface, the minuteſt part of the original face. In this a head of good clay may be moulded, and therein the eyes are to be opened, and other neceſſary amendments made. This ſecond face being anointed with oil, a ſecond mould of calcined alabaſter is made, conſiſting of two parts joined lengthways along the ridge of the noſe; and herein may be caſt, with the ſame matter, a face extremely like the original.

If finely powdered alabaſter, or *plaſter of Paris*, be put into a baſon over a fire, it will, when hot, aſſume the appearance of a fluid, by rolling in waves, yielding to the touch, ſteaming, &c. all which properties it again loſes on the departure of the heat; and being thrown upon paper will not at all wet it, but immediately diſcover itſelf to be as motionleſs as before it was ſet over the fire; whereby it appears, that a heap of ſuch little bodies as are neither ſpherical, nor otherwiſe regularly ſhaped, nor ſmall enough to be below the diſcernment of the eye, may, without fuſion, be made fluid, barely by a ſufficiently ſtrong and various agitation of the particles which compoſe it; and, moreover, loſe its fluidity immediately upon the ceſſation thereof.

Two or three ſpoonfuls of burnt alabaſter, mixed up thin with water, in a ſhort time coagulate, at the bottom of a veſſel full of water, into a hard lump, notwithſtanding the water that ſurrounded it. Artificers obſerve, that the coagulating property of burnt alabaſter will be very much impaired or loſt, if the powder be kept too long, eſpecially if in the open air, before it is made uſe of; and when it hath been once tempered with water, and ſuffered to grow hard, they cannot, by any burning or powdering of it again, make it ſerviceable for their purpoſe as before. Boyle's Works Abr. vol. i. p. 133, 318, 341.

This matter, when wrought into veſſels, &c. is ſtill of ſo looſe and ſpongy a texture, that the air has eaſy paſſage through it. Mr. Boyle gives an account among his experiments with the air-pump, of his preparing a tube of this *plaſter*, cloſed at one end and open at the other, and on applying the open end to the cement, as is uſually done with the receivers, it was found utterly impoſſible to exhauſt all the air out of it; for freſh air from without preſſed in as faſt as the other, or internal air, was exhauſted, though the ſides of the tube were of a conſiderable thickneſs. A tube of iron was then put on the engine; ſo that being filled with water, the tube of *plaſter of Paris* was covered with it; and on uſing the pump, it was immediately ſeen, that the water paſſed through into it as eaſily as the air had done, when that was the ambient fluid. After this, trying it with Venice turpentine inſtead of water, the thing ſucceeded very well; and the tube might be perfectly exhauſted, and would remain in that ſtate ſeveral hours. After this, on pouring ſome hot oil upon the turpentine, the caſe was much altered; for the turpentine melting with this, that became a thinner fluid, and in this ſtate capable of paſſing like water into the pores of the *plaſter*. On taking away the tube after this, it was remarkable that the turpentine, which had pervaded and filled its pores, rendered it tranſparent, in the manner that water gives tranſparency to that ſingular ſtone called *oculus mundi*. In this manner, the weight of air under proper management, will be capable of making ſeveral ſorts of glues penetrate *plaſter of Paris*; and not only this, but baked earth, wood, and all other bodies porous enough to admit water on this occaſion. Phil. Tranſ. N° 122.

Plaſter of Paris, diluted with water into the conſiſtence of a ſoft or thin paſte, quickly ſets or grows firm, and at the inſtant of its ſetting, has its bulk increaſed; for Mr. Boyle has found, that a glaſs veſſel, filled with the fluid mixture and cloſely ſtopped, burſts whilſt the mixture ſets, and ſometimes a quantity of water iſſues through the cracks.

This expanſion of the *plaſter* in paſſing from a ſoft to a firm ſtate, is one of its valuable properties; rendering it an excellent matter for filling cavities in ſundry works, where other earthy mixtures would ſhrink and leave vacuities, or entirely ſeparate from the adjoining parts.

It is probable alſo, that this expanſion of the *plaſter* might be made to contribute not a little to the elegance of the impreſſions which it receives from medals, &c. by properly confining the ſoft matter, that its expanſion may force it into the minuteſt traces of the figure; the expanſion of the matter doing the ſame office as the preſſure by which the wax is forced into the cavities of a ſeal.

Plaſter of Paris promotes the fuſion of forged IRON.

This ſubſtance is commonly uſed for taking caſts and impreſſions from figures, buſts, medals, &c. as it is adapted to the double uſe of making both caſts and moulds for forming them. See *Impreſſions of* MEDALS.

PLASTERING. The modern taſte runs greatly into *plaſtering*; and it were much to be wiſhed that this art could be again brought to its ancient perfection. In our beſt buildings the *plaſtered* walls and ceilings crack and fly, and in a little time grow damp, or moulder to decay. The Romans had an art of rendering their works of this kind much more firm and durable, and there is no reaſon to deſpair of reviving this art by proper trials.

The ancient *plaſtering* of theſe people, preſerved to this time, where it has not met with violent blows or injuries from accidents is ſtill found as firm and ſolid, as free from cracks or crevices, and as ſmooth and poliſhed on the ſurface, as if made of marble. The bottoms and ſides of the Roman aqueducts were made of this *plaſtering*, and endured many ages without hurt, unleſs by accidents; witneſs that wherein ſome yards are ſtill to be found on the top of the Pont de Carde, near Nifmes, for the ſupport of which that famous bridge was built to carry water to the ſaid town. The roofs of houſes, and the floors of rooms at Venice are covered with a ſort of *plaſter*, made of later date, and yet ſtrong enough to endure the ſun and weather for ſeveral ages, without cracking or ſpalling, and without much injury from people's feet.

The ſecret of preparing this Venetian *plaſter* is not among us; but it would be worth while to try whether ſuch a ſubſtance might not be made by boiling the powder of gypſum dry over the fire, for it will boil in the manner of water; and when this boiling or recalcining was over, the mixing with it reſin, or pitch, or both together, with common ſulphur, and the powder of ſea-ſhells. If theſe were all mixed together, and the water added to it hot, and the matter all kept hot upon the fire till the inſtant of its being uſed, ſo that it might be laid on hot, it is poſſible this ſecret might be hit upon.

Wax and oil of turpentine may be alſo tried as additions: theſe being the common ingredients in ſuch cements as we have accounts of as the firmeſt. Strong ale-wort is by ſome directed to be uſed, inſtead of water, to make mortar of lime-ſtone of a more than ordinary ſtrength. It is poſſible, that the uſe of this tenacious liquor to the powdered ingredients of this propoſed *plaſter*, might greatly add to their ſolidity and firmneſs. Phil. Tranſ. N° 93.

PLASTIC, Πλαστικὸς, from πλάσσω, of πλάττω, or πλάσσω, *fingo*, *I faſhion*, *form*, &c. imports as much as *formative*, or a thing endued with a faculty of forming or faſhioning a maſs of matter after the likeneſs of a living being.

Some of the ancient Epicureans, and perhaps the Peripatetics too, imagine a *plaſtic* virtue to reſide in the earth, or at leaſt to have anciently reſided therein; and that it was by means hereof, and without any extraordinary intervention of a Creator, that it firſt put forth plants, &c. Nay, ſome of them, whether ſeriouſly or not we do not undertake to determine, taught that animals, and even man, were the effects of this *plaſtic* power.

Some learned modern writers have ingenuouſly contended for the doctrine of a *plaſtic nature*, which they have deſcribed to be an incorporeal created ſubſtance, endued with a vegetative life, but not with ſenſe or thought, penetrating the whole created univerſe, being co-extended with it, and under God, moving matter ſo as to produce the phenomena, which cannot be ſolved by mechanical laws; active for ends unknown to itſelf, not being conſcious of its own actions, and yet having an obſcure idea of the action to be exerted upon. Dr. Cudworth reaſons thus: ſince neither all things are produced fortuitouſly, or by the unguided mechaniſm of matter, nor God himſelf may reaſonably be thought to do all things immediately and miraculouſly, it may well be concluded, that there is a *plaſtic* nature under him, which as an inferior

and

and subordinate instrument, doth drudgingly execute that part of his providence, which consists in the regular motion of matter; yet so as that there is also, besides this, a higher providence to be acknowledged, which, presiding over it, doth often supply the defects of it, and sometimes over-rule it: for as much as this *plastic* nature cannot act electively, nor with discretion. This doctrine, he says, hath had the suffrage of the best philosophers of all ages; Aristotle, Plato, Empedocles, Heraclitus, Hippocrates, Zeno, and the Stoics, and the latter Platonists and Peripatetics, as well as the chemists and Paracelsian, maintained this doctrine. Intell. System. vol i. p. 147, &c. Birch's Ed. More's Imm. of the Soul, lib. iii. cap. 12.

PLASTICE, Πλαστικὴ, the PLASTIC *art*, a branch of SCULPTURE; being the art of forming figures of men, birds, beasts, fishes, plants, &c. in plaister, clay, fluceo, or the like.

The workmen concerned herein are also called *plastæ*, πλάσται.

Plastice differs from carving, because here the figures are made by addition of something that is wanting; but in carving, always by subtraction of what is superfluous.

The *plastic art* is now chiefly used, among us, in fret-work cielings; but the Italians apply it also to the mantlings of chimneys with great figures.

PLAT, a popular term, among *Mariners*, &c. for a sea-chart.

PLAT-*veins*, in the *Manege*, called in French *arts*, are the veins in which we bleed horses, one in the lower part of each shoulder, when we bleed a horse in the shoulders; and in the flat part of the thighs.

PLATS, in a *Ship*, flat ropes made of rope-yarn, and twilled into forms; they serve to save the cable from galling in the hawse, or to wind about the flukes of the anchors, to save the pennant of the sore-sheet from galling against them.

PLATA, PLATE, in *Commerce*, a Spanish term, signifying silver; as vellon, which they pronounce vellion, signifies copper.

These two terms are not only used to express the species of those metals struck in Spain, but also to distinguish between their several monies of account. Thus they say, a DUCAT of *plata*, and a ducat of vellon; a rial of *plata*, and a RIAL of vellon: which denominations augment and diminish the value by almost one half; thirty-four maravedis of *plata* being equal to sixty-three of vellon; and the PIECE *of eight* being only two hundred and seventy-two MARAVEDIS of *plata*, but five hundred and ten of vellon. See COIN.

PLATÆ, a word used by some anatomical writers to express the scapulæ.

PLATALEA, in *Ornithology*. See SPOON-*bill*.

PLATAMON, a word used to express a low and smooth rock, just appearing above water.

PLATANARIA, in *Botany*, a name by which some authors have called the *spargarium*, or bore-reed, from its round echinated fruit, which in shape and size much resemble those of the *platanus*.

PLATANUS, in *Botany*. See PLANE-*tree*.

PLAT-BAND, in *Gardening*, a border, or bed of flowers, along a wall, or the side of a parterre; frequently edged with box, &c.

PLAT-BAND, in *Architecture*, is any flat square moulding, whose height much exceeds its projecture. See *Tab. Architect. fig.* 25.

Such are the faces, or fascia, of an architrave, and the *plat-bands* of the modillions of a cornich.

The *plat-band* is signified in Vitruvius, and others, by the words FASCIA, *taenia*, and *corsa*.

PLAT-BAND of a door or window, is used for the lintel, where that is made square, or not much arched.

These *plat-bands* are usually crossed with bars of iron when they have a great bearing: but it is much better to case them by arches of discharge built over them.

PLAT-BANDS of flutings, the lists, or fillets, between the flutings of columns.

PLATE, in *Commerce*, denotes gold or silver wrought into vessels for domestic uses.

PLATE, in *Heraldry*, is a round, flat piece of silver, without any impression; but, as it were, formed ready to receive it.

The term is used only by the English heralds. In other nations they are known by the name of BESANTS *argent*.

PLATE, a term used by our sportsmen to express the reward given to the best horse at our races.

The winning a *plate* is not the work of a few days to the owner of the horse, but great care and preparation are to be made for it, if there is any great dependence on the success. A month is the least time that can be allowed to draw the horse's body clear, and to refine his wind to that degree of perfection that is attainable by art.

It is first necessary to take an exact view of his body, whether he be low or high in flesh; and it is also necessary to consider whether he be dull and heavy, or brisk and lively, when abroad. If he appear dull and heavy, and there is reason to suppose it is owing to too hard riding; or, as the jockies express it, to some grease that has been disliked in hunting, and has not been removed by sweating, then the proper remedy is half an ounce of diapente, given in a pint of good sack; this will at once remove the cause, and revive the creature's spirits. After this, for the first week of the month, he is to be fed with oats, bread, and fruit beans, giving him sometimes the one, and sometimes the other, as he likes best; and always leaving some in the locker, that he may feed at leisure when he is less alone. When the groom returns at the feeding time, whatever is left of this must be removed, and fresh given; by this means the creature will soon become high spirited, wanton, and full of play. Every day he must be rode out an airing, and every other day it will be proper to give him a little more exercise; but not in such a degree as to make him sweat too much.

The beans and oats in this case are to be put into a bag, and beaten till the hulls are all off, and then winnowed clean; and the bread, instead of being chipped in the common way, is to have the crust clean cut off.

If the horse be in good flesh and spirits when taken up for his month's preparation, the diapente must be omitted; and the chief business will be to give him good food, and so much exercise as will keep him in wind, without over sweating or tiring his spirits. When he takes larger exercise afterwards, towards the end of the month, it will be proper to have some horses in the place to run against him. This will put him upon his mettle, and the beating them will give him spirits.

This, however, is to be cautiously observed, that he has not a bloody heat given him for ten days or a fortnight before the *plate* is to be run for; and that the last heat that is given him the day before the race, must be in his cloaths: this will make him run with greatly more vigour, when stripped for the race, and feeling the cold wind on every part. In the second week the horse should have the same food and more exercise, and in the last fortnight he must have dried oats, that have been hulled by beating; after this they are to be wetted in a quantity of whites of eggs, beaten up, and then laid out in the sun to dry; and when as dry as before, the horse is to have them. This sort of food is very light of digestion, and very good for the creature's wind. The beans in this time should be given more sparingly, and the bread should be made of three parts wheat, and one part beans. If he should become coslive under this course, he must then have some ale and whites of eggs beaten together: this will cool him, and keep his body moist.

In the last week the mash is to be omitted, and barley-water given him in its place; and every day, till the day before the race, he should have his full of hay; then he must have it given him more sparingly, that he may have time to digest it; and in the morning of the race-day, he must have a mash or two of white bread, soaked in sack, and the same just before he is led out of the field. This is an excellent method, because the two extremes of fullness and fasting are at this time to be equally avoided; the one hurting his wind, and the other occasioning faintness that may make him lose. After he has had his food, the litter is to be shook up, and the stable kept quiet, that he may be disturbed by nothing till he is taken out to run. See RACING.

PLATE, in *Gunnery*. The *prize-plates* are two *plates* of iron on the cheeks of a gun-carriage, from the cap-square to the centre, through which the prize-bolts go, and on which the hand-spike rests when it poises up the breech of the piece. *Breast-plates* are the two *plates* on the face of the carriage, one on each cheek. *Train-plates* are the two *plates* on the cheeks at the train of the carriage. *Bulidge plates* are the fixed *plates* on the wheel of a gun-carriage, where the fellows are joined together, and serve to strengthen the bulidges.

PLATES, *copper*, in *Engraving*. See COPPER-*plates*.

PLATES, *ground*, in *Building*. See GROUND-*plates*.

PLATES, *pintle*. See PINTLE.

PLATE-*glass*. See GLASS.

PLATES, *colours of glass*. See COLOURS.

PLATE-*lines*, in the *Manege*, a woven strap, four fathoms long, three fingers broad, and as thick as one. It is used for miling a horse's legs and sometimes for taking him down, in order to facilitate several operations of the farrier. Some improperly give the name of *plate-lines* to a MARTINGALE.

PLATEA, in *Ornithology*, the name of a bird of the long-necked kind, approaching to the nature of the stork and heron, and called in English the SPOON-*bill*.

PLATESSA, in *Ichthyology*, a name by which Ausonius and some other authors have called the paller-fish, or common PLAICE.

PLAT-FOND, in *Architecture*, the same as SOFFIT.

PLAT-FORM, in the *Military Art*, an elevation of earth, a floor of wood or stone, on which cannon is placed to fire on the enemy.

Such are the mounts in the middle of the curtins. On the rampart there is always a *platform*, where the cannon are mounted.

It is made by the heaping up of earth on the rampart, or by an arrangement of mashers, rising insensibly for the cannon to roll on, either in a casemate, or an attack in the outworks.

Plat-forms are generally laid sloping towards the parapet nine or ten inches; this declivity carries off the rain, prevents the gun from recoiling so much when fired as it would do if laid level; and when loaded, it is more easily brought to the embrasure.

In temporary batteries, the *plat-forms* are made of planks laid across ground timbers or sleepers, usually five in number, and kept steady by stakes at each end; there is usually a *plat-form made* to each gun: it is commonly about eighteen feet long, eight feet broad next the parapet, and about fourteen feet broad at the tail, the intermediate spaces between the *plat-forms* serving for the shot and other necessaries. When a *plat-form* is to be laid on marshy ground, first lay a floor or two of fascines; cover these with hurdles, twelve or fifteen feet long, and six or seven broad; on these lay a floor of three or four inches of earth, and therein lay the sleepers, and over them the planks. When a BATTERY is built of stone or brick, the *plat-form* is generally a flat stone-pavement ranging the whole length of the battery: this, on account of its resisting the injuries of the weather for a long time, is to be preferred to planks: but in case of bombardment such a *plat-form* is to be avoided, because the shells will not only break the pavement, but also, by driving about the broken stones, do much mischief to the troops.

All practitioners are agreed, that no shot can be depended on, unless the piece be placed on a solid *plat-form*; for if the *plat-form* shakes with the first impulse of the powder, it is impossible but the piece must likewise shake; which will alter its direction, and render its shot uncertain.

To prevent this accident, the *plat-form* is usually made extremely firm to a considerable depth backwards, so that the piece is not only well supported in the beginning of its motion, but likewise through a great part of its recoil. However, it is sufficiently obvious, that when the bullet is separated from the piece, it can be no longer affected by the trembling of the piece or *plat-form*; and by a very easy computation it will be found, that in a piece ten feet in length, carrying a bullet of twenty-four pounds, and charged with fifteen pounds of powder, the bullet will be out of the piece before it has recoiled half an inch; whence if the *plat-form* be sufficiently solid at the beginning of the recoil, the remaining part of it may be much slighter, since its unsteadiness beyond the first half inch will have no influence on the direction of the shot: and hence a more compendious method of constructing *plat-forms* may be found out. New Princip. of Gunnery, p. 42.

PLAT-FORM, in *Architecture*, is a row of beams, which support the timber-work of a roof, and lie on the top of the wall where the entablature ought to be raised.

PLAT-FORM is also used for a kind of terrace, or broad, smooth, open walk, at the top of a building, from whence we may take a fair prospect of the adjacent country.

Hence an edifice is said to be covered with a *plat-form*, when it is flat at top, and has no ridge.

Most of the oriental buildings are thus covered, as were all those of the ancients. Cæsar was the first among the Romans who procured leave to build his house with a ridge or pinnacle.

PLAT-FORM, in a *Man of War*. See ORLOP.

PLATTASMOS, or πλατασμὸς, *Lalage*, formed from πλατὺς, *wide*, a word used by many authors to express a fault in pronunciation, owing to a person's opening his mouth too wide, and thence speaking indistinctly.

PLATICORIA, formed of πλατὺς, *wide*, and κόρη, *pupil*, a word used by medical writers to express a preternatural dilatation of the pupil of the eye, usually owing to a paralytic disorder.

PLATINA, in *Natural History*, a metallic substance, lately discovered, analogous to the perfect metals, and especially to gold: many of the properties of which it possesses; and, in consequence of modern experiments, supposed to be itself a *perfect* metal.

The name *platina* seems to be a diminution of *plata, silver*, and expresses the most obvious appearance of this body, which is that of a silver-coloured metal in small grains. It is also called *platina de Pinto*, probably because Pinto is the name of some particular district, which affords it; *Juan blanco, white Jack, white regule, white mock metal*, and *diabolus metallorum*, because it was found to be refractory and unmanageable, and, though resembling true metals in aspect and weight, found to elude all attempts for smelting or running it down; and *to blanc, or white gold*, on account of its relation to gold.

PLATINA, *history of*. D'Ulloa is the first writer who mentions *platina* by name. In his voyage to South America, in 1735, and the following years, printed at Madrid, in 1748, speaking of the gold and silver mines of Quito, he relates, that in the territory of Choco there were gold mines which they were obliged to abandon, because the mineral was mixed with *platina*; which he describes as a stone, in hard, that it is not easily broken by a blow upon an anvil; that it is not subdued by calcination; and that it is very difficult to extract the metals it contains, even with much labour and expence.

In 1741, Mr. Charles Wood found some *platina* in Jamaica, which was brought thither from Carthagena; and in his account of it he observes, that the Spaniards have a method of calling it into different kinds of ores, which are common in the Spanish West Indies. But Dr. Lewis has since found, that this calt metal, which has been often confounded with the native or mineral *platina*, is a composition of the true *platina* with some other metallic bodies. Some have supposed that *platina* is the produce of the East as well as West Indies; but this does not appear to be the case. It is undoubtedly obtained from the Spanish West Indies, and in the greatest quantities from the provinces of Quito and Peru.

Soon after the importation of this substance into England, it was found that the Spaniards, having discovered that it sustained all the ordinary trials of gold, possessed nearly the same specific gravity, and rendered gold much less pale than silver, had a method of adulterating gold with it, which was so brittle, that it could not be refined nor applied to any use. And it is said, that, in order to prevent frauds of this kind, the king of Spain ordered the mines that afforded it to be stopped up: but there is now no danger of such fraud, since modern experiments have discovered easy means for distinguishing with certainty gold debased by *platina*, and for completely parting the two metals, however they may be blended together by accident or by design.

The first experiments that were made with this substance, were those of Mr. Wood; one of which, viz. the capellation of the cast metal with lead, was afterwards repeated, more circumspectly, by Dr. Brownrigg, who presented an account of the whole to the Royal Society by Dr. Watson, and the account was published in the Phil. Trans. vol. xliv. art. 12. p. 584, &c.

But we owe the greatest part of our knowledge concerning this substance, to the numerous and accurate experiments of Dr. Lewis, published, in six papers, in the forty-eighth and forty-ninth volumes of the Transactions; and farther pursued in his excellent work, intitled Commercium Philosophico-Technicum.

In 1752, Mr. Scheffer, of the Swedish Academy, published two Memoirs on the same subject; and another, containing remarks on some of the experiments of Dr. Lewis in 1757. A French translation of the four first papers of Dr. Lewis, and the two first Memoirs of Mr. Scheffer, was published at Paris by M. Morin, in 1758, under the title of La Platine, l'Or blanc, ou le huitieme Metal, &c. In consequence of this publication, Messrs. Marggraaf, Macquer, and Baume, directed their attention to this subject; the experiments of the former were first published among the Memoirs of the Berlin Academy, for the year 1757, printed in 1759, and since in the first volume of his Chemical Writings; those of the two latter gentlemen were published in the Memoirs of the Academy of Paris, for 1758, printed in 1763.

Some farther experiments on this singular anomalous substance have been more lately made and published by Messrs. de Buffon, de Lisle, and Morveau. See Buffon's Supplement, vol. ii. and Rozier's Journal for September 1775.

PLATINA, *description and properties of*. *Platina* in grains, as it is brought into England, is of a shining whitish colour, somewhat approaching to that of silver, but less white. Its colour is not tarnished or altered by air or moisture, or by any vapours usually floating in the atmosphere, even by those which discolour silver, and appears to be equally permanent with that of pure gold. As it is incapable of acquiring rust, it is also perfectly indestructible in the fire. The grains are of various sizes; some few being as large as linseed, but most of them much smaller. In figure, some of them are triangular, others circular, but most of them flat, with a smooth surface, and the edges and angles generally rounded off. Some few of the grains are weakly attracted by a magnetic bar.

Dr. Ingenhousz (Phil. Trans. vol. lxvi. part i. p. 262), observes, that every one of the particles of some fine *platina*, which he examined, obeyed the magnet, more or less,

less, except some transparent stony particles; and that even these were all magnets in themselves; or that each particle had two poles, which he could change at pleasure by the application of magnetical bars. In those grains of *platina*, which Dr. Lewis examined, he found an intermixture of several heterogeneous particles: such as a considerable quantity of blackish dust, some particles of which were of a deep sparkling black colour, resembling the black sand of Virginia, and were much attracted by a magnetic bar; and others of a brownish hue, not attracted at all, with which several bright particles, that appeared to be fragments of the grains of the *platina*, were intermixed. The magnetic dust just mentioned seemed to be fragments of other irregular dark-coloured particles, which resembled pieces of emery or lead-stone; some of these were attracted by the magnet very weakly, and others not at all. There were also some rough yellow particles, very malleable, which appeared to be gold, with some mixture of *platina*.

Most of the gold particles of *platina*, says Dr. Ingenhousz, ubi supra, are evidently attracted by the magnet, and discovered upon the surface of the water their two distinct poles; and this magnetical quality he ascribes to some *platina* mixed with the gold.

Dr. Lewis farther observes, that the grains of *platina* consist likewise of a few globules of quick-silver with some particles of the *platina* intermixed, and pretty strongly adhering; which have been also discovered by M. Margraaf. They contain also fine colourless transparent particles which were hard to break under the hammer, and were not sensibly acted upon by aqua fortis, and which are probably fragments of quartz: and a few irregular particles of a jet-black colour, which easily broke, and laid on a red-hot iron emitted a yellowish smoke, and smelt like burning coal.

Dr. Lewis observes, that there is reason to suspect, that this mineral does not come to us in its native form; but that it has probably been ground in mills and worked with quick-silver, in order to extract the particles of gold intermixed with it: and some later accounts confirm this conjecture, that *platina* is found in large masses, and is reduced into smooth grains by stamping and grinding. M. de Buffon expressly says, that a portion of credit had allured him, that *platina* is sometimes found in large masses, and that he had seen a lump of it weighing no less than twenty pounds, which had not been melted, but had been taken in that state out of the mine.

However this be, all the matters above mentioned are entirely adventitious to the *platina*, and their quantities are very various: the magnetic or ferruginous matter being always the most considerable and possibly the only constant admixture.

When we consider the heterogeneous particles with which *platina* is combined, we need not wonder at the different accounts which different writers give of its specific gravity. Dr. Lewis found, by weighing hydrostatically several different particles, that the gravity compared with that of water was very nearly as seventeen to one, never less than 16.500 nor greater than 17.200. Dr. Pemberton and Mr. Ellicott reported it to be about 17; and Dr. Davies found the gravity of a parcel which he tried to be 17.233. M. Margraaf states the gravity of *platina* to that of gold as 18\frac{1}{2} to 19: and Dr. Lewis, having taken previous pains to cleanse and prepare a quantity of the larger grains, in order to come as near as possible to the specific weight of the pure *platina*, found its gravity on many trials to be upwards of eighteen; though the microscope still discovered a portion of blackish matters in the cavities of the grains. These accounts are very different from those which result from the experiments of M. de Buffon, and M. Tillet, who affirm, that *platina* is specifically lighter than gold by at least an eleventh or twelfth part, and that its density is a mean between that of gold and iron.

The great weight of *platina*, Dr. Lewis apprehends, instead of being a proof of its containing gold, affords rather a presumption of its being a ponderous body distinct from gold.

By experiments on this substance, some of the purer grains of it have been found, by gentle strokes of a flat hammer on a smooth anvil, to bear extension into thin plates, without breaking or cracking about the edges; and therefore *platina* appears to be a malleable metal; though different grains seemed to possess this property in a different degree, some being more brittle than others, and all being more brittle when red hot than when cold. The brittleness of those that cracked soonest and were most easily reduced to powder is supposed to proceed from some accidental cause.

As fusion is necessary for the application of metals to use, chemists have made their utmost efforts to melt *platina*. The most violent heat which could be raised in air-furnaces, or by the united action of several large bellows, has been applied repeatedly, and continued a long time without success. In all these trials the grains of *platina* remained unaltered in form and weight, and were only agglutinated to each other, nearly as sand is by exposure to violent heat, but so slightly, that they were separable by the smallest effort.

Messrs. Macquer and Beaumé exposed *platina* during five days and five nights to the greatest heat of a glass-house furnace, which trial did only confirm the unfusibility and unalterability of *platina* by ordinary fires, as it was found to be only a little agglutinated, and its weight to be a little increased; which latter phenomenon has also been observed by Mr. Margraaf and Dr. Lewis. This increase of weight M. Macquer very justly suspects to be owing to the CALCINATION of some heterogeneous substances mixed with the *platina*.

Platina has been also exposed to the fire in contact with the burning fuel, and yet has come out of the crucible unmelted and unaltered in its form. However Messrs. Macquer and Beaumé, having exposed it to the focus of a large burning-glass twenty-two inches diameter, and of twenty-eight inches focus, melted a little of it in a minute. It first smoked, then emitted sparks, and those parts of it melted well which were exposed to the centre of the focus. These chemists carefully examined the properties of this *platina*. The melted parts, they observe, were distinguished from the others by a brilliancy like that of silver, and by a rounded, shining, polished surface. They are easily flattened upon an anvil, and formed into very thin plates without cracking or splitting; so that these grains seemed to be much more malleable than *platina* in its natural state. These metals by repeated strokes of the hammer became hard and brittle, like all other metals, especially gold and silver; and by annealing, their malleability was restored, as that of other metals is also by the same means. It has been also found, that *platina* is fusible by the electric fire; and Dr. Ingenhousz observes, that common fire diminishes the magnetical virtue of *platina*, but that electrical fire increases it. M. de Lisle has lately discovered a method of melting *platina*, by dissolving the crude substance in aqua regia, precipitating it from the acid menstruum by sal ammoniac, and by fusing this precipitate, without addition, in a double crucible, exposed to the intense heat of a large fire, excited by double bellows. M. Morveau has repeated this experiment: from seventy-two grains of *platina* he obtained a regulus, which weighed 50\frac{1}{2} grains, and seemed to have undergone a very imperfect fusion, for it did not adhere to the crucible nor take its form; but seemed to be the *platina* merely revived: its specific gravity also was found to be to that of water no more than as 10.245 to 1; but it was found to be nearly as malleable as silver, and when it had been sufficiently hammered, its specific gravity was found to be to water as 20.170 to 1.

Platina resists as perfectly as gold the action of the vitriolic, marine, and nitrous acids; and, indeed, of any pure acid, however applied. These acids, concentrated or diluted, may be boiled for any length of time upon *platina*, without dissolving an atom of it; but aqua regia, the proper menstruum for gold, is also the solvent of *platina*. M. Macquer having tried different proportions of the nitrous and marine acids, found that an aqua regia, composed of equal parts of the two acids, dissolve most of this metal; but *platina* appears to require a much greater quantity of this solvent, in what way soever it is prepared, than gold, and to dissolve with greater difficulty. The aqua regia, employed by Margraaf consisted of one part of sal ammoniac and sixteen parts of aqua fortis; and one ounce of *platina* required twenty-four ounces of this menstruum: but sixteen ounces of the aqua regia of Macquer dissolved, by digestion, one ounce of *platina*: and Dr. Lewis, preparing an aqua regia by diluting 10\frac{1}{2} ounces of strong smoking spirit of nitre with eight ounces of water, and afterwards the mixture from six ounces of common salt, dissolved one ounce of *platina* with fourteen ounces of the menstruum; but by performing the operation in close vessels, and by distillation and cohobation, a much less quantity of the aqua regia would have been sufficient.

Solutions of *platina* in aqua regia, when saturated with the metal, which requires considerable heat, are of a dark, almost opake, brown-red colour; when only slightly impregnated, they are yellow like those of gold. They communicate a rich tinge to watery fluids, but, according to Dr. Lewis, impart no durable colour or stain to other bodies; in which respect they differ from solutions of gold: though Macquer observes, that, in certain circumstances, they tinge the skin and other animal matters with a blackish-brown colour, and that ether mixed with this solution, by agitation, quickly separates from it, and becomes tinged with a fine yellow colour, as it does with the

the solution of gold: but this fact is contrary to the observation of Dr. Lewis, who affirms, that *platina* is not taken up from its solution in aqua regia by ether. Solutions of *platina* are observed to cryſtallize much more eaſily than thoſe of gold; and the cryſtals are nauſeous, ſlightly acid, and corroſive.

Platina may be precipitated from its ſolvent by fixed and volatile alkalis; the precipitates by volatile alkalis being of a dark kind of red colour, are conſiderably ſparkling, but thoſe of the fixed being of a paler dull reddiſh, with little brilliancy. M. Margraaf has diſcovered, that the mineral alkali produces no precipitation at all. The ſame writer alſo obſerves, that when ſolution of *platina* is mixed and ſaturated with a lixivium of fixed alkali that has been calcined with blood, it yields a fine blue precipitate, which in certain circumſtances proves as beautiful as the beſt *Pruſſian* BLUE: count de Milly has made a ſimilar obſervation, and inferred from it that iron is a conſtituent part of *platina*: but probably the *platina* which theſe gentlemen uſed was impure; more eſpecially as M. Morveau has ſince found, that no Pruſſian blue was formed on the addition of phlogiſticated alkali, if the experiment was made with thoſe particles of the *platina* that were inſenſible to the magnet.

It has ſufficiently appeared by many experiments, that *platina* is not only of itſelf refractory in the fire, but obſtinately reſiſts the additions and managements, by which every other known metallic body is corroded, diſſolved, or changed into a vitreous ſtate. Neither borax, nor alkali, nor nitre, which calcines all the known metallic bodies, except gold, ſilver, and mercury, nor common ſalt, nor vitriolic ſalts, nor the eſſential ſalts of urine, nor the phoſphoric acid, nor the black flux, nor ſulphur, nor earthy bodies, nor vitreous bodies, produce any material alteration in *platina*. However, Dr. Lewis diſcovered that the liver of ſulphur is capable of diſſolving *platina*, as it alſo does gold by fuſion.

Platina, like gold, is capable of being alloyed with all metals, and in theſe alloys exhibits intereſting phenomena. We are indebted to Dr. Lewis for many important facts and obſervations to this purpoſe; the principal of which we ſhall here ſubjoin. *Platina* appears to be capable of amalgamating with mercury, though with difficulty, and after long trituration in a ſolution of common ſalt with water, and a few drops of ſpirit of ſalt; part of it being diſſolved by the mercury, and the undiſſolved parts coated with it. Equal parts of *platina* and biſmuth being dropped into a mixture of black flux, and common ſalt fuſed in a crucible, and being urged with a quick fire ſtrongly excited by bellows, melted together in a few minutes; and the *platina* was ſo blended with the biſmuth, that no grain of it could be ſeen. All the compoſitions of *platina*, with different proportions of biſmuth, were extremely brittle; and on expoſure to the air changed from a dull greyiſh colour to a yellowiſh, purpliſh or bluiſh, and at length to a purpliſh black.

Platina may be melted with tin in the ſame manner, in all proportions, from equal parts of the two metals to twenty-four of tin; and it appears from ſeveral alloys of this kind, that *platina* diminiſhes the malleability of tin, renders its texture coarſer, and debaſes or darkens its colour more or leſs, as the *platina* is in greater or leſs proportion. And the malleability poſſeſſed by both metals ſeparately, is deſtroyed by their combination, when the *platina* is about one-third of the tin, or upwards.

Lead alſo may be alloyed in different proportions with *platina*, nearly as tin may; with this difference, that a much greater fire is neceſſary for the formation of this latter alloy, eſpecially when the quantity of *platina* is great. The metal, reſulting from it, has a leafy or fibrous texture, and a dark colour, ſomewhat approaching to a purple or blue; or it has a diſpoſition to acquire theſe colours freedily in the air, and changes at length into black. When the two metals, fuſed together, are left in a crucible to cool, a conſiderable part of the *platina* ſeparates, and falls to the bottom.

Platina alſo melts with arſenic, as Scheffer obſerved, and Dr. Lewis has confirmed; but leſs perfectly than with other metals; but it is next to impoſſible to fuſe it ſufficiently, in order to its being poured out into a mould. All the arſenicated pieces are very brittle, internally of a greyiſh colour, and a looſe granulated texture; and they retain the ſame appearance for many years.

Of all metallic matters zinc may be moſt eaſily alloyed with *platina*, and moſt effectually diſſolved by fuſion. Dr. Lewis obſerved, that theſe alloys did not appear very different from pure zinc; but that when the proportion of *platina* is conſiderable, their grain is cloſer, their colour is leſs clear, and more bluiſh than that of zinc. They do not tarniſh, nor change colour, by expoſure to air; and they are harder than zinc, and have not the malleability of this ſemi-metal. With regulus of antimony, *platina* formed a darker and harder compound than the pure regulus.

Silver and *platina* may be melted and alloyed together in equal parts with a very violent fire. The alloy, thus formed, is much harder and darker-coloured than ſilver, and of a large grain, although it preſerves ſome ductility. Theſe qualities are leſs ſenſible when one part of *platina* is added to ſeven parts of ſilver; but this alloy is ſtill coarſer grained and leſs white than ſilver. This coniſtence of grain ſhews an imperfect union; and, indeed, ſilver and *platina* do not ſeem to unite very perfectly; for Dr. Lewis obſerves, that when the alloy of theſe two metals was left, after fuſion, in the crucible, a conſiderable part of the *platina* was ſeparated, and ſunk to the bottom. The *platina* did not appear to communicate any good quality to the ſilver, excepting a greater hardneſs. Gold and *platina* may be combined in various proportions, with conſiderable heat; and from ſeveral experiments Dr. Lewis concludes, that *platina* diminiſhes the malleability of gold much leſs than it does that of the other malleable metals; and infinitely leſs than lead, tin, iron, and the brittle metals do that of gold; that in conſiderable proportions it debaſes the colour of gold far more than the uſual alloy, communicating a peculiar and remarkably ill colour; and that it both hardens and debaſes the colour of ſtandard gold, with copper alloy, much more than fine gold; that in ſmall proportions, as one forty-ſeventh and downwards, it does not ſenſibly injure either the colour or malleability of gold, and conſequently, that large proportions of *platina* mixed with gold, are diſcoverable at ſight; but that ſmall proportions, if perfectly united with the gold, will not betray themſelves either to the eye, or in the workman's hands. Copper ſeems to be moſt improved by being alloyed with *platina*. When, indeed, a large proportion of *platina* is added to copper, as equal parts or two-thirds, the alloy is hard, brittle, and coarſe; but when a leſs quantity of *platina* is added, as from $\frac{1}{3}$ to $\frac{1}{12}$, or even leſs, a golden-coloured copper is produced, very malleable, harder, ſuſceptible of a finer poliſh, ſmoother grained, and much leſs ſubject to calcination and ruſt than pure copper. Dr. Lewis was not able to fuſe forged iron with *platina*, but he alloyed *platina* with caſt IRON, by throwing one part of *platina* to four parts or more of the iron, when it was juſt beginning to flow.

This alloy was much harder, and much leſs ſubject to ruſt, than pure iron, and ſuſceptible of a very fine poliſh. The ſame ingenious philoſopher combined *platina* at the ſame time with two metallic matters, ſuch as braſs compoſed of copper and zinc, and bronze compoſed of copper and tin. The latter alloy was hard, and capable of receiving a fine poliſh; equal parts of *platina* and braſs formed a compound very hard and very brittle, capable of receiving a very fine poliſh, and not ſubject to tarniſh. This metal might be advantageouſly employed for the ſpecula of teleſcopes.

The cupellation of *platina* was one of the moſt deſirable diſcoveries with regard to this ſubſtance; becauſe on the ſucceſs of this operation depended our obtaining compact and malleable maſſes of pure *platina*, in the ſame ſtate with a metal which has been well *fuſed*, and of which all ſorts of utenſils might be made, either by caſting or forging. Dr. Lewis made many unſucceſsful experiments with this view; the proceſs of cupelling with lead went on well at firſt, but as the quantity of lead diminiſhed, the matter became leſs fuſible, and required a ſtronger fire, till at laſt it could not, with the greateſt degree of heat, be made to flow at all. The regulus obtained was always dark-coloured, rough, and brittle, and weighing more than the *platina* originally employed. Meſſrs. Scheffer and Margraaf were equally unſucceſsful with Dr. Lewis; Meſſrs. Macquer and Beaumé tried what might be effected by a long duration of fire, and, therefore, they kept the matter expoſed to a violent fire for about fifty hours, and in this way they obtained *platina*, which, though tarniſhed and rough in its ſurface, was entirely white and ſhining, eaſily ſeparable from the cupel, and a little diminiſhed in weight, which afforded a certain proof that no lead remained in it. This *platina* was alſo ductile, and capable of extenſion under the hammer. Dr. Lewis purſuing the ſame kind of proceſs, and uſing vehement fires for twenty hours or more, ſucceeded in obtaining *platina*, ſo much diſengaged from the lead, as to be malleable; but he obſerves that the ſucceſs of the operation very much depends upon ſpreading the metal thin upon the bottom of the cupel; the thinner the metalline plates, the ſooner and the more effectually were they freed from the lead, and rendered malleable. How far, he ſays, the diſſipation of lead or biſmuth may be practicable on maſſes of a conſiderable thickneſs, his experiments have not abſolutely determined. M. Macquer ſeems to make no doubt that *platina*

this may thus be rendered manageable by the workmen in large quantities, so as to furnish us with burning concaves, specula for reflectors, innumerable vessels and utensils for chemical and culinary uses, and almost all the works of the locksmith. He observes, that *platina* would for these purposes be an excellent material, as its vivid and brilliant polish is never tarnished by any kind of vapour, and as it not only resists the action of air, water, fire, acids, and the voracious metals as well as the purest gold does, but joins to these admirable qualities a property still more precious, which gold wants, viz. the force and hardness of iron.

The affinities of *platina*, as stated by Dr. Lewis, are as follow; observing, that the body placed uppermost is always understood to have a greater affinity to that which is immediately under it than to the third or lowermost.

1. Mercury.	2. Mercury.	3. *Platina.*	4. Aqua regia.	5. Aqua regia.
Platina.	Gold.	Lead.	Zinc.	Iron.
Lead.	*Platina.*	Iron.	Cobalt.	*Platina.*

Aqua regis, and solution of iron from vitriol	Copper.	Tin.	Mercury.	Nickel.
Gold.	*Platina.*	*Platina.*	*Platina.*	*Platina.*

One of the most important advantages hitherto obtained from the experiments made upon this metal, is that of preserving the fineness and value of gold, and preventing it from being fraudulently debased by the admixture of a body so much resembling itself. The principal methods of alloying any mixture of *platina* and gold, and of separating them from one another, are as follow: the first is by *cupelling a mixture of platina* and gold with mercury, and grinding the amalgam for a considerable time with water, in which process the *platina* will be gradually thrown out, and the gold retained by the quicksilver. Another method is by mixing a few drops of a solution of *platina* with above a hundred times the quantity of a solution of gold, and gradually adding a pure fixed alkaline salt as long as it occasions any effervescence or precipitation. The remaining liquor in this case will be so yellow, that it has been judged the *platina* would discover itself, though its proportion had been less than a thousandth part of that of *gold*. A *third* mode of separating *platina* and gold is that of precipitation, by means of mineral fixed alkali; for when this alkali is mixed with a solution of gold containing *platina*, the gold alone is precipitated, and all the *platina* remains dissolved. Another method is by precipitation of the *platina* with sal ammoniac: for this purpose to a solution of the metal in aqua regia, add a small quantity of the solution of sal ammoniac in water; and if the gold contained any *platina*, the liquor will instantly grow turbid, and a fine yellow or reddish precipitate will quickly fall to the bottom; if the gold were pure, no precipitation or change of transparency would ensue. The *fifth* method of separation is by means of inflammable liquors: let the compound to be examined be dissolved in aqua regia, the solution mingled with twice its quantity or more of rectified spirit of wine, and the mixture suffered to stand for some days in a glass slightly covered, the gold will rise to the surface, leaving the *platina* dissolved. Otherwise, add to the solution of the metal in aqua regia about half its quantity of any colourless essential oil; shake them well together, and suffer them to rest, the oil will rise immediately to the surface, carrying the gold with it, and leave the *platina* dissolved in the acid under it. Or, the gold may be taken up still more readily and more perfectly by ether, or the ethereal spirit of wine. But after all, the most effectual and advantageous method of purifying GOLD from the metallic bodies commonly found mixed with it appears to be by dissolving it in aqua regia, and precipitating with a large proportion of a filtered solution of green vitriol: the same process serves for purifying it from *platina*; the vitriolic solution precipitating the gold, and leaving the *platina* dissolved. This property, which *platina* possesses, of being precipitated by green vitriol, was first discovered by Mr. Scheffer.

From all the preceding properties of *platina*, and other circumstances enumerated by Dr. Lewis, Scheffer, Margraaf, Macquer, Bewme, &c. we may infer, that *platina* is a mineral substance, whose metallic aspect, great weight, malleability, and perfect infusibility with all the common metallic bodies, are sufficient characters of its being a true metal; which abides fixed and unalcined in the strongest fires, is no wise ironified by nitre, or by lead or bismuth, nor dissolved by vitreous bodies, and which is, therefore, a perfect metal of the same class with gold and silver, and, perhaps, more perfect or less alterable than these; which with the colour of silver, possesses the specific weight and several other of the most discriminating properties of gold; resisting, equally with gold, many agents, which dissolve, corrode, dissolve, or scorify silver, and the base metals, as air and sulphureous exhalations, the nitrous, marine, and vitriolic acids, both in their liquid state, and when resolved by fire into fume, and sulphur and antimony in fusion. With these valuable properties, it adds some to gold itself, making it both less soft and less fusible, which no other alloy does; so that some a due proportion of it bids fair to remove those inconveniencies, which the enamellers complain of, when they work upon plates either of fine gold or of alloyed gold. But, though *platina* undoubtedly belongs to the same genus of bodies with gold and silver, of which genus no more than these three species have been hitherto discovered; and though it agrees with gold in many of its distinctive properties, yet there are other important characters in which it remarkably differs from gold. Its white colour; its want of fusibility; the singular alterations which it produces in some of the other metals, and in gold itself; its being difficultly and sparingly acted upon by hepar sulphuris, by which gold is plentifully dissolved; its solution in aqua regia giving no stain to the substances which by solutions of gold are tinged red or purple; its being in part precipitated from its solution by sal ammoniac, which does not in the least precipitate gold; its being precipitated only partially by vegetable fixed alkalis, and by volatile alkalis, and not in the least by the mineral alkalis, or by solution of green vitriol, by all which gold is precipitated entirely; its precipitates by alkalis having nothing of the fulminating power, which precipitates of gold possess in a more eminent degree than any other known kind of matter; its solutions in aqua regia suffering no decomposition from essential oils or ether, by both which gold is imbibed from the acid, not from inflammable spirits, by which gold is revived and thrown out in its proper form; its being rejected, on infusion, from its solution in quicksilver, while gold is retained and continues dissolved; its being separable from gold, in virtue of these distinctions of affinity, without augmentation or diminution of either metal, as easily and as perfectly as any one metal is separable from any other, are characters abundantly more than sufficient for establishing a specific difference between *platina* and gold. However, there are some authors who still maintain, that *platina* is not a true metal, or semimetal, of a peculiar kind: Vogel apprehends that it is a mixed mineral; the dross of the small amalgam-works in which gold is separated by quicksilver from a mixed ore. De Bonon supposes *platina* to be a compound of gold and iron, such as would result from a combination of these metals in the proportion of three-fourths of the former to one of the latter, formed by the action of some volcano, or by the water which has forced upon those two metals in a state of dissolution, and united them in the form under which they actually appear in *platina*. The principal arguments he alledges in favour of this hypothesis are, that *platina* has neither the ductility nor malleability that constitute the character of all metals; that its specific gravity is less than others have supposed, and that the ferruginous sand, which is so abundant in all the specimens of *platina*, is not peculiar to that substance, or to the mines from which it is taken, as he has found a matter of the same nature, though in very small quantities, in several iron mines. Supplement, *ubi supra*. See on the subject of this article D'd. Chem. art. *Platina*, and particularly the complete history and analysis of it by Dr. Lewis in his Commercium Philosophico-Technicum, &c. p. 443—612.

PLATONIA, in *Natural History*, a name given by the modern Greeks to the *pyxe* of Aristotle, and of other ancient writers in that language. This is the *ornus platyceros*, or broad-horned flag. Some have translated this *ilama*, but they are to be understood in this as meaning the *ilama* of their own times, not that of the ancients; that being the *isarus*, or chamois-goat, not any animal of the flag kind, nor by any means meriting that title.

PLATONIC, something that relates to Plato, his school, philosophy, opinions, or the like.

PLATONIC *bodies* are the same with what we otherwise call REGULAR *bodies*.

PLATONIC *love* denotes a pure spiritual affection, subsisting between the different sexes, abstracted from all carnal appetites, and regarding no other object but the mind, and its beauties: or it is even a sincere disinterested friendship, subsisting between persons of the same sex, abstracted from any selfish views, and regarding no other object but the person.

The term took its rise from the philosopher Plato, a strenuous advocate for such kind.

The world has a long time laughed at Plato's notions of love and friendship. In effect, they appear airy chimeras, contrary to the intentions of nature, and inconsistent with the great law of self-preservation; which love and friendship are both ultimately resolvable into.

PLATONIC *year*, or the *great year*, is a period of time determined by the revolution of the equinoxes, or the space wherein the ſtars and conſtellations return to their former places, in reſpect of the equinoxes.

The *Platonic* year, according to Tycho Brahe, is 25816; according to Ricciolus, 35920; and according to Caſſini, 24800 years.

This period, which is more than five times the age of the world, once accompliſhed, it was an opinion among the ancients, that the world was to begin anew, and the ſame ſeries of things to return again.

PLATONISM, the doctrine and ſentiments of Plato, and his followers, with regard to philoſophy, &c.

The founder of this ſyſtem of philoſophy, Plato, the ſon of Ariſto, was an Athenian, related by his father to Codrus, and by his mother to Solon; born on the ſeventh of Thargelion, in the eighty-ſeventh Olympiad, about the year of the world 3625, who, after having ſpent his youth in exerciſes of the body, painting, poetry, rhetoric, and muſic, became a diſciple of Socrates. After his maſter's death, he applied himſelf to Cratylus and Hermogenes; till, being a maſter of the Greek philoſophy, he travelled into Italy, where he learnt alſo that of the Pythagoreans. Thence he proceeded into Egypt; where, in ſeveral years reſidence, he became fully acquainted with the ſecrets of the Egyptian prieſts.

At his return to Athens he began to teraſh the flock of learning he had collected, among his countrymen; philoſophizing daily in the Academy, a delicious villa in the neighbourhood of that city. And hence his diſciples, among whom were Xenocrates, Ariſtotle, Lycurgus, Demoſthenes, and Iſocrates, were called *Academics*. In phyſics, he chiefly followed Heraclitus; in ethics and politics, Socrates; and in metaphyſics, Pythagoras.

After his death, at the age of eighty-one years, two of the principal of his diſciples, Ariſtotle and Xenocrates, continuing his office, and teaching, the one in the Academy, the other in the Lyceum, formed two ſects, under different names, though, in other reſpects, the ſame; the one retaining the denomination of ACADEMICS, the other aſſuming that of PERIPATETICS.

In after-times, about the firſt ages of the Chriſtian church, the followers of Plato quitted the title of *Academiſts*, and took that of *Platoniſts*.

It is ſuppoſed to have been at Alexandria, in Egypt, that they firſt aſſumed their new title, after having reſtored the ancient academy, and re-eſtabliſhed Plato's ſentiments; which, in proceſs of time, had many of them been laid aſide.

Porphyry, Plotin, Iamblichus, Proclus, and Plutarch, are thoſe who acquired the greateſt reputation among the Greek Platoniſts; and, among the Latins, Apulcius and Chalcidius. Among the Hebrews, Philo Judæus. The modern Platoniſts own Plotin the founder, at leaſt the reformer, of their ſect.

The *Platonic philoſophy* appears very conſiſtent with the Moſaic; and a great party of the primitive fathers follow the opinions of that philoſopher, as being favourable to Chriſtianity. Juſtin is of opinion, that Plato could not learn many things which he has ſaid in his works, from mere natural reaſon; but thinks he might have learnt them from the books of Moſes, which he might have read when in Egypt.

Hence Numenius the Pythagorean expreſly calls Plato the *Attic Moſes*, and upbraids him with plagiariſm; becauſe he ſtole his doctrine about the world and God from the books of Moſes.

Theodoret ſays expreſly, that he has nothing good and commendable about the Deity, and his worſhip, but what he ſtole from the Hebrew theology; and Clemens Alexandrinus calls him the *Hebrew philoſopher*.

Gale is very particular in his proof of the point, that Plato borrowed his philoſophy from the Scriptures, either immediately, or by means of tradition; and, beſide the authority of the ancient writers, he brings ſome arguments from the thing itſelf. As, e. gr. Plato's confeſſion, that the Greeks borrowed their knowledge of the one infinite God, from an ancient people, better and nearer to God than they; by which people, our author makes no doubt, he meant the Jews, from his account of the ſtate of innocence; as, that man was born of the earth, that he was naked, that he enjoyed a truly happy ſtate, that he converſed with brutes, &c. In effect, from an examen of all the parts of Plato's philoſophy, phyſical, metaphyſical, and ethical, this author finds, in every one, evident characters of its ſacred original.

As to the manner of the creation, Plato teaches, that the world was made according to a certain exemplar, or idea, in the divine Architect's mind. And all things in the univerſe, in like manner, he ſhews, do depend on the efficacy of eternal ideas. This ideal world is thus explained by Didymus: "Plato ſuppoſes certain patterns, "or exemplars, of all ſenſible things, which he calls "ideas; and, as there may be various impreſſions taken "off from the ſame ſeal, ſo, he ſays, are there a vaſt "number of natures exiſting from each idea." This idea he ſuppoſes to be an eternal eſſence, and to occaſion the ſeveral beings in nature to be ſuch as itſelf is. And that moſt beautiful and perfect idea, which comprehends all the reſt, he maintains to be the world.

Farther, Plato teaches that the univerſe is an intelligent animal, conſiſting of a body and a ſoul, which he calls *θεον γενητον, the generated God*, by way of diſtinction from the ἀιδιον, or immutable eſſence, who was the cauſe of the generated God, or the univerſe.

According to Plato, there were two ſorts of inferior and derivative gods; the mundane gods, all of which had a temporary generation with the world; and the ſupramundane eternal gods, which were all of them, one excepted, produced from that one, and dependent on it as their cauſe. It is obſerved by the learned Dr. Cudworth, that though ſome of the ancient fathers impute to Plato the opinion, that matter was an unmade ſelf-exiſtent being, there ſeems to be no ſufficient ground for their ſo doing; and Porphyry, Iamblichus, Proclus, and other Platoniſts, do not only profeſſedly oppoſe the ſame as falſe, but alſo as that which was diſſonant from Plato's principles. However, he acknowledges, that Plato did aſſert a plurality of gods, meaning animated or intellectual beings, or dæmons, ſuperior to men, to whom honour and worſhip are due, and applying the appellation to the ſun, moon, and ſtars, and alſo to the earth. Nevertheleſs he aſſerts, at the ſame time, that there was one ſupreme God, the ſelf-originated being, the maker of the heaven and earth, and of all thoſe other gods. He alſo maintains, that the Pſyche, or univerſal mundane ſoul, which is a ſelf-moving principle, and the immediate cauſe of all the motion which is in the world, was neither eternal nor ſelf-exiſtent, but made or produced by God in time; and above this ſelf-moving Pſyche, but ſubordinate to the ſupreme Being, and derived by emanation from him, which he calls τὸ ὂν, and τ' ἀγαθὸν, the *good*, he ſuppoſes an immoveable Nous or intellect, which was properly the Demiurgus, or former of the world.

The firſt matter whereof this body of the univerſe was formed, he obſerves, was a rude indigeſted heap, or chaos: now, adds he, the creation was a mixed production; and the world is the reſult of a combination of neceſſity and underſtanding, i. e. of matter, which he calls neceſſity, and the divine wiſdom: yet ſo that mind doth rule over neceſſity; and to this neceſſity he aſcribes the introduction and prevalence both of moral and natural evil; maintaining, however, that the evils reſulting from the neceſſity of imperfect beings are over-ruled by Mind or God for good.

The principles, or elements, which Plato lays down, are fire, air, water, and earth.

He ſuppoſes two heavens, the *empyreum*, which he takes to be of a fiery nature, and to be inhabited by angels, &c. and the *ſtarry* heaven, which he teaches is not adamantine, or ſolid, but liquid and ſpirable.

With regard to the human ſoul, Plato maintained its tranſmigration, and conſequently its future immortality and pre-exiſtence. He aſſerted, that human ſouls are here in a lapſed ſtate, and that ſouls ſinning ſhould fall down into theſe earthly bodies. Euſebius expreſly ſays, that Plato held the ſoul to be ungenerated, and to be derived by way of emanation from the firſt cauſe.

His phyſics, or doctrine *de corpore*, is chiefly laid down in his Timæus, where he argues on the properties of body in a geometrical manner; which Ariſtotle takes occaſion to reprehend in him. His doctrine *de mente* is delivered in his tenth book of Laws, and his Parmenides.

St. Auguſtine commends the *Platonic philoſophy*; and even ſays, that the *Platoniſts* were not far from Chriſtianity. He adds, that the generality of the new *Platoniſts* of his time embraced the faith; and he expreſly acknowledges, that it was by means of the Platonic ſyſtem he was able to underſtand the doctrine of the trinity. Juſtin Martyr profeſſes, that Plato's doctrine was of the utmoſt advantage to him, in helping him to believe the myſteries of the Chriſtian faith. To which it may be added, that it was, in good meaſure, by Plato's help, that Origen confuted Celſus.

Indeed, the late author of Platoniſme Devoile carries things to an extravagant length, when he contends, that the dogmata of our religion are only the opinions of Plato; that the fathers give us nothing of the myſteries thereof, but what they learnt from him; and that Chriſtianity is only *Platoniſm* veiled, or covered over. To which opinion, however, M. le Clerc ſeems alſo a little inclined.

It is certain, that most of the celebrated fathers were Platonists, and borrowed many of their explanations of scripture from the Platonic system. In order to account for this fact, we may observe, that, towards the conclusion of the second century, a new sect of philosophers, called the modern, or later Platonics, arose of a sudden, spread with amazing rapidity through the greatest part of the Roman empire, swallowed up almost all the other sects, and proved extremely detrimental to Christianity. The school of Alexandria in Egypt, instituted by Ptolemy Philadelphus, renewed and reformed the Platonic philosophy. The votaries of this system distinguished themselves by the title of Platonics, because they thought that the sentiments of Plato, concerning that most noble part of philosophy, which has the Deity and things invisible for its objects, were much more rational and sublime than those of the other philosophers. This new species of *Platonism* was embraced by such of the Alexandrian Christians as were desirous to retain, with the profession of the Gospel, the title, the dignity, and the habit of philosophers. Ammonius Saccas was its principal founder, who was succeeded by his disciple Plotinus, as he was by Porphyry, the chief of those formed in his school. From the time of Ammonius until the sixth century, this was almost the only system of philosophy that was publicly taught at Alexandria. It was brought into Greece by Plutarch, who renewed at Athens the celebrated Academy, from whence issued many illustrious philosophers. The general principle on which this sect was founded, however the partizans of it might differ with respect to particular opinions, was, that truth was to be pursued with the utmost liberty, and to be collected from all the different systems in which it lay dispersed. None, however, who were ambitious to be ranked among these new Platonists, called in question the main doctrines; those, for example, which regarded the existence of one God, the fountain of all things; the eternity of the world; the dependance of matter upon the Supreme Being; the nature of souls; the plurality of gods; the method of interpreting the popular superstitions, &c.

In the fourth century, under the reign of Valentinian, a dreadful storm of persecution arose against the Platonists; many of whom, being accused of magical practices, and other heinous crimes, were capitally convicted. In the fifth century Proclus gave new life to the doctrine of Plato, and restored it to its former credit in Greece; with whom concurred many of the Christian doctors, who adopted the Platonic system. The Platonic philosophers were, in general, opposers of Christianity; but in the sixth century, Chalcidius gave the pagan system an evangelical aspect; and those who, before it became the religion of the state, ranged themselves under the standard of Plato, and repaired to that of Christ, without any considerable change of their system. Under the emperor Justinian, who issued a particular edict, prohibiting the teaching of philosophy at Athens, which edict seems to have been levelled at modern *Platonism*, all the celebrated philosophers of this sect took refuge among the Persians, who were, at that time, the enemies of Rome; and though they returned from their voluntary exile, when the peace was concluded between the Persians and Romans, A. D. 533, they could never recover their former credit, nor obtain the direction of the public schools. Thus, says Mosheim, expired that famous sect, which was distinguished by the title of the modern or later Platonics, and which, for a series of ages, had produced such divisions and tumults in the Christian church, and which had been, in other respects, prejudicial to the interests and progress of the Gospel. For a further account of this sect, see ECLECTICS.

Platonism, however, prevailed among the Greeks, and was by them, and particularly by Gemistius Plethon, introduced into Italy, and established, under the auspices of Cosmo de Medicis, about the year 1439; who ordered Marsilius Ficinus to translate into Latin the works of the most renowned Platonists.

PLATONISTS. See PLATONISM, and ACADEMICS.

PLATOON, or PLOTTOON, formed, by corruption, of the French *peloton*, a *button*, or *clue of thread*, in *War*, a small body of men, drawn out of a battalion of foot, and placed between the squadrons of horse, to sustain them; or in ambuscades, straits, and defiles, where there is not room for whole battalions, or regiments.

Platoons are also used when they form the hollow square, to strengthen the angles.

The grenadiers are generally posted in *platoons*.

A battalion is generally divided into fifteen *platoons*, exclusive of the grenadiers, which form two or four *platoons* more, as occasion may require.

PLATOON *firing*. See FIRING.

PLATTS, on *Board a Ship*. See PLATE.

PLATYCEROS *ovis*, in *Natural History*, the name given by Gesner and some others to a species of sheep, commonly called *ovis laticauda*, or the broad-tailed SHEEP.

PLATYOPHTHALMON, a name given by some to antimony, from its use among the ladies of old time, to make their eye-brows broad and black.

PLATYRYNCHOS, in *Ichthyology*, a name given by some to the NASUS, or *nose*, a fresh water fish, caught in the Danube, and most of the large rivers in Germany, and much resembling the chub.

PLATYSMA *myoides*. See MUSCLE.

PLATYSTERNOS, a word used by the old physicians to express a person with a very broad chest or sternum.

PLAUSUS, among the Romans. See ACCLAMATION.

PLAY, *ludus*. See GAME, and GAMING.

PLAY, in the *Doctrine of Chances*, is used for the probability of the play's ending in a given number of games.

PLAY, in *Poetry*, &c. See DRAMA, TRAGEDY, COMEDY, &c.

PLAY-HOUSE. See THEATRE, AMPHITHEATRE, &c.

The most ancient English *play-houses* were the Curtain in Shoreditch, and the Theatre. In the time of Shakspeare, who commenced a dramatic writer about the year 1592, there were no less than ten theatres open, four private houses, and six that were called public theatres. Most, if not all of Shakspeare's *plays*, were performed either at the Globe, which was an hexagonal building, partly open to the weather, and partly covered with reeds, on the southern side of the river Thames, called the Bankside, and a public theatre, where they always acted by day-light; or at the theatre in Black-friars, which was a private *play-house*, and where plays were usually represented by candle-light. Both these belonged to the same company of comedians, viz. his majesty's servants, which title they assumed after a licence had been granted to them by king James, in 1603; having before this time been called the servants of the lord chamberlain. The exhibitions at the Globe seem to have been calculated chiefly for the lower class of people, and those at Black-friars for a more select and judicious audience. The former was a summer, and the latter a winter theatre. Many of our ancient dramatic pieces were performed in the yards of carriers' inns, in which, in the beginning of queen Elizabeth's reign, the comedians, who then first united themselves in companies, erected an occasional stage. The form of these temporary *play-houses* seems to be preserved in our modern theatre. Many circumstances concur to render it probable, that our ancient theatres, in general, were only furnished with curtains, which opened in the middle, and a single scene composed of tapestry, sometimes ornamented with pictures. In the year 1605 Inigo Jones exhibited an entertainment at Oxford, in which moveable scenes were used; but they were not then used in the public theatres. When Sir William Davenant first opened, by virtue of his patent, the duke of York's theatre in Lincoln's Inn fields, in the spring of the year 1662, with one of his own plays, the Siege of Rhodes, then scenes made their first appearance upon the English stage; and about the same time actresses were also introduced, probably by him, in imitation of the foreign theatres; and Mrs. Perserton is said to have been the first woman that appeared on the English stage. Before this time, female characters were represented by boys or young men. In the time of Shakspeare plays began at one o'clock in the afternoon, and the exhibition was usually finished in two hours; and so late as 1667, they commenced at three o'clock. See Malone's Supplemental Observations to Steevens's edition of Shakspeare.

If any persons shall in *plays*, &c. jestingly or prophanely use the name of God, they shall forfeit 10*l.* 3 Jac. I. cap. 21. And players speaking any thing in derogation of religion, &c. are liable to forfeitures and imprisonments. 1 Eliz. Also acting plays or interludes on a Sunday is subject to penalties, by 1 Car. I. cap. 1. No person shall act any new *play*, or addition to an old one, &c. unless a true copy thereof, signed by the master of the *play-house*, be sent to the lord chamberlain fourteen days before it be acted, who may prohibit the representing any stage play; and persons acting contrary to such prohibitions shall forfeit 50*l.* and their licences, &c. Stat. 10 Geo. II. cap. 28. And by this statute, no licence is to be given to act plays, but in the city and liberties of Westminster, or places of his majesty's residence. Ibid.

PLEA, *placitum*, in *Law*, that which either party alledgeth for himself in court, in a cause then depending to be tried.

Pleas are either *of the crown*, or *common pleas*.

PLEAS *of the crown* comprehend all crimes and misdemeanors in which the king, on behalf of the public, is the plaintiff.

plaintiff. Such are treasons, felonies, misprisions of either, and trespass.

Pleas, common, include all civil actions depending between subject and subject. The former of these were the proper object of the jurisdiction of the court of king's bench; the latter of the court of common *pleas*.

Pleas are of two sorts; viz. DILATORY *pleas*, and *pleas to the action*.

Dilatory *pleas* are such as tend merely to delay or put off the suit, by questioning the propriety of the remedy, rather than by denying the injury. And they are, to the jurisdiction of the court, called foreign *pleas*, or, to the disability of the plaintiff, and in ABATEMENT.

Pleas to the action are such as dispute the very cause of suit.

Pleas of this kind are general to the declaration, or a special *plea*, in bar. A general *plea* traverses, thwarts, and denies at once the whole declaration, without offering any special matter whereby to evade it. Thus, in debt on contract, it is, *He owes nothing*; in debt on bond, *It is not his deed*, or *He paid it at the day*; in action of the case upon a promise, *He hath not promised*; in trespass upon the case, *Not guilty*; in covenant, *Performance of covenants*, &c. In real actions, *No wrong done*. *No disseisin*; and in a writ of right, *That the tenant hath more right to hold than the demandant has to demand*. These *pleas* are called the general issue, because they amount at once to an issue, or a fact affirmed on one side, and denied on the other. A special *plea* contains the matter at large, concluding to the declaration or action; and special *pleas* are many, as by *durefs* and *per minas*, and in JUSTIFICATION, that in assault and battery, the plaintiff struck the first blow, &c. In trespass, that the defendant did the thing complained of in right of some office which warranted him to do; or, in an action of slander, that the plaintiff is nearly as bad a man as the defendant call'd he was.

Special *pleas* in answer to the plaintiff's declaration are of two kinds; *pleas* in bar, and in abatement; and every *plea* must be pleaded either in bar, to the action brought, or in abatement of the writ; upon which the action is framed, or it is but a discourse, and not a *plea*.

PLEAS, in *Equity*, may be either to the jurisdiction, shewing that the court has no cognizance of the cause; or to the person, shewing some disability in the plaintiff, as by outlawry, excommunication, and the like; or in bar, shewing some matter wherefore the plaintiff can demand no relief, as an act of parliament, a fine, a release, or a former decree. And the truth of this *plea* the defendant is bound to prove, if not upon it by the plaintiff.

PLEAS *of the forest*. Ranulph earl of Chester, 2 Hen. III. granted to his barons of Cheshire an ample charter of liberties, *exceptis placitis ad gladium meum pertinentibus*. The reason of the exception was, that William the Conqueror gave the earldom of Chester to his half-brother Hugh, commonly called Lupus, ancestor of this Ranulph, *sicuti sui liberi ad gladium, sicut ipse rex tenuit de forestâ & coronâ*.

Accordingly, in all indictments for felony, murder, &c. in the county palatine, the form was, *Contra pacem domini comitis, gladium & dignitatem suam*; or, *contra dignitatem gladii Cestriæ*. Such were the *pleas* for the dignity of the earl of Chester.

PLEAS, *court of common*, called also common bench. See COURT *of common pleas*.

PLEADING, *placitatio*, a discourse spoken at the bar, in defence of the cause of a party.

From the time of the Conquest, all *pleadings* was performed in French, till the time of Edward III. when it was appointed, that the *pleas* should be *pleaded* in English, but that they should be entered, or recorded, in Latin. But now by 4 Geo. II. cap. 26. it is enacted, that all proceedings in courts of justice shall be in English.

At Athens, and even in France and England, it was prohibited to have any formed, or prepared *pleadings*, or to amuse the court with long artificial harangues; only, in important matters, it was the settled custom to begin the *pleadings* with a passage in holy Scripture.

It is but of late years that eloquence was admitted to the bar, where it has been much practised and encouraged.

Among the Athenians, an equal time was allowed both parties to *plead*, which was measured by a water hour-glass; and in order to see justice done in this respect, there was an officer appointed to distribute the water to each, whence he was called EPHYDOR.

PLEADINGS, in the stricter sense, are all the allegations of the parties to a suit, made after the count, or declaration, till issue is joined.

In this sense the *pleadings* express what is contained in the bar, replication, and rejoinder; and not what is in the declaration itself. Hence defaults in the matter of declaration are not comprised within the *miſpleading*, or insufficient *pleading*; which only extends to that committed in the bar, replication, or rejoinder.

PLEASURE, the effect of a sensation, or perception, agreeable to the mind, or of the gratification of some appetite.

Pleasures may be distinguished into two kinds. The first, those which anticipate, or go before the reason; such are all agreeable sensations. These are popularly called *pleasures of sense*, or *of the body*.

The second are those which do not precede, or anticipate, either the senses or reason. These we call *pleasures of the mind*. Such is the joy arising from a clear perception of some future good, or the confused sensation of a present one.

For an instance of each. A man frequently finds *pleasure* in eating a fruit he was before unacquainted with: this is *anticipating pleasure*, which he feels before he knows the fruit to be good. On the other hand, a hungry hunter expects, or perhaps actually finds victuals; where the joy he conceives is a *pleasure* that follows from the knowledge of his present or future good.

Pleasure and *pain* seem to be no other than engines in nature's hand, whereby we are directed to consult our own preservation, and avoid our ruin. To things that may contribute to the one, as food, venery, &c. she has annexed *pleasure*; and to those that may convince to the other, as hunger, diseases, &c. pain. She durst not leave it to our discretion, whether we would preserve and propagate the species, or not; but, as it were, constrains us to both. Were there no *pleasure* in eating, nor pain in hunger, what numbers would be starved, through negligence, forgetfulness, or slothfulness? What is it induces people to the office of generation, but *pleasure*? Without this the world had scarce subsisted to this time.

Among the multiplicity of things to be done, and to be avoided, for the preservation of animal life, &c. how should we have distinguished between the one and the other, but for the sensation of *pleasure* and pain? These are not only spurs to urge us on, but also guides, to direct us whither we are to go. Wherever nature has fixed a pleasure, we may take it for granted, she there enjoins a duty; and something is to be there done, either for the individual, or for the species.

Hence it is, that our *pleasures* vary at different stages of life; the *pleasures*, e. gr. of a child, a youth, a grown man, an old man, &c. all tending to those particular things required by nature in that particular state of life, either for the preservation, simply, or, jointly, for that and propagation, &c.

Hence, from the different constitutions of the body, at different ages, it were very easy to account for all the particular tastes and *pleasures* thereof; not by deducing the *pleasures* mechanically from the disposition of the organs in that state, but by considering what is necessary for the perfection and well-being of the individual in that state, and what it is to contribute to that of the species. In a child, e. gr. mere preservation in the present state is not enough; it must likewise grow: to bring this to pass, nature has made the returns of hunger, &c. more frequent, as well as more acute, and the *pleasures* of feeding more exquisite. And that the excess of aliment, in proportion to the bulk of the body, may be dispensed with, she has made one of the great *pleasures* of the state to consist in a series of sportive exercises; by means whereof the parts of the body come to be opened and expanded, and arrive at maturity. This done, the *pleasures* that conduced thereto disappear; and others, suited to the new state, succeed.

For the PLEASURES *of hearing, muſic*, &c. see BEAUTY, MUSIC, &c.

PLEASURE *boat*, among the *Ancients*. See THALAMEGUS.

PLEBANUS was anciently the title of a *rural* DEAN.

The denomination arose hence, that these deaneries were then affixed to the *plebanie*, or chief mother-church within such a district; which, at first, was usually ten parishes.

PLEBANUS seems also to have been used for a parish-priest of such a large mother-church, as was exempt from the jurisdiction of the ordinary; so that he had the authority of a rural dean committed to him by the archbishop; to whom the church was immediately subject.

PLEBEIAN, *plebeius*, a person of the rank of the populace, or common people.

The term is chiefly used in speaking of the ancient Romans; who were divided, about the time of Tarquin's expulsion, into senators, knights, and *plebeians*, or commons.

The *plebeians* were those who could not claim their descent from the ancient senators appointed by Romulus and the kings who succeeded him.

PLEBEIAN *games*, were games celebrated by the Roman people,

people, in remembrance, as some say, of their reconciliation with the senators, after their expulsion from the city, in the year of Rome 261; or, according to others, in token of their public rejoicing, when the kings were driven from Rome U. C. 245, and the people enjoyed their liberty. These games were celebrated in the Circus for three days, and commenced on the seventh of the calends of December. Adrian instituted *plebeian* games in the circus U. C. 874.

PLEBISCITUM, among the Romans, a law enacted by the common people, at the request of the tribune, or some other plebeian magistrate, without the intervention of the senate.

PLEBISCITUM is more particularly applied to the law which the people made, when, upon some misunderstanding with the senate, they retired to the Aventine mount.

PLECHAS, a word used by Hippocrates to express that region of the body which is terminated backward by the anus, forward by the pudenda, and sideways by the hips.

PLECTANÆ, a word used by some to express the cornua uteri, and by others for any plexus of vessels.

PLECTRONIA, in *Botany*, a genus of the *pentandria monogynia* class. Its characters are, that it has five petals inserted in the empalement; and the fruit is a berry containing two seeds. There is only one species.

PLECTRONITÆ. See CONICHTHYODONTES.

PLECTRUM, a word used by some anatomical writers to express the styloide process of the os petrosum; by others for the uvula; and by others for the tongue.

PLECTRUM, among the *Ancients*, an instrument used in playing upon the LYRE. We have a description of it in Mem. Acad. Inscrip. vol. v. p. 168.

PLEDGE, *plegius*, in *Common Law*, a surety, or gage, either real or personal, which the plaintiff, or demandant, is to find, for his prosecuting the suit.

The word is sometimes also used for FRANK *pledge*.

To PLEDGE, in *Drinking*, denotes to warrant, or be surety to one, that he shall receive no harm while he is taking his draught.

The phrase is referred, by our antiquaries, to the practice of the Danes, heretofore, in England; who frequently used to stab, or cut the throats of the natives while they were drinking.

PLEDGERY, or PLEGGERY, suretiship, or an undertaking, or answering, for another.

The appellant shall require the constable and marefchal to deliver his pleggs, and to discharge them of their *pledgery*; and the constable and marefchal shall ask leave of the king to acquit his pleggs, after that the appellant is come into the lists to do his devoir. Orig. Jur. ex Vet. Cod. MS. in Bibl. Selden.

PLEDGES *of goods for money*, &c. See PAWN.

PLEDGET, in *Surgery*, a kind of flat tent, made, not to enter a wound, but to be laid upon it, to imbibe the superfluous humours, and keep it clean and dry.

PLEGII *de retorno*, &c. in *Law*. See REPLEVY, and RETORNO *Habendo*.

PLEGIS *acquietandis*, a writ that lies for a surety, against him for whom he is surety, in case he pay not the money at the day. Fitz. Nat. Brev.

PLEIADES, Πλειάδες, in *Astronomy*, an assemblage of seven stars in the neck of the constellation Taurus.

They are thus called from the Greek πλεῖν, *navigare*, *to sail*; as being terrible to mariners, on account of the rains and storms that frequently rise with them.

The Latins call them *corniculæ*, from *cor*, *horn*; because of their rising about the vernal equinox.

The largest is of the third magnitude, and is called *Lucida Pleiadum*. See their several longitudes, latitudes, magnitudes, &c. under TAURUS.

There are now only six stars visible in *Pleiades*, and this appears to have been the case so long ago as the time of Ovid:

Quæ septem dicti, sex tamen esse solent.

PLEIADES, in *Mythology*, were the seven daughters of Atlas, called Maya, Electra, Taygeta, Alcyone, Celeno, and Merope. These Atlantides, it is said, were translated to the heavens, and formed the *Pleiades*; the meaning of which fable is, that Atlas first observed these stars, and called them by the names of his daughters.

PLEIADES, *poetical*, is a name which the Greeks gave to seven celebrated poets, flourishing under the reign of Ptolemy Philadelphus.

In imitation of the Greeks, Ronsard formed a *Pleiades* of French poets under the reign of Henry II. It consisted of Daurat, Ronsard, du Bellay, Belleau, Baif, Tyard, and Jodelle.

On the same model, some of their authors afterwards projected a new *Pleiades* of the Latin poets of the last century; but they were not agreed about the names of those that should compose it; much less on him who should be the *Lucida Pleiadum*. M. Baillet named F. Rapin, F. Commire, F. de la Rue, M. de Santeuil, M. Menage, M. du Perier, and M. Petit.

PLEMMYROS, a word used by the old Greek writers to express a redundance of humours. Its proper signification is the flowing in of the tide.

PLENARTY, in *Law*, a term used in ecclesiastical matters, to denote that a benefice is full, or possessed of an incumbent.

In which sense it stands opposed to VACANCY.

Institution, by six months, is a good *plenarty* against a common person, but not against the king, without induction. See INSTITUTION, and INDUCTION.

PLENARY, formed of the Latin *plenarius*, of *plenus*, *full*, something complete, or full. Thus we say, the pope grants *plenary indulgences*, i. e. full and entire remissions of the penalties due to all sins.

PLENE *administravit*, in *Law*, is a plea pleaded by an executor or administrator, where they have administered the deceased's estate faithfully and justly before the action brought against them. On *plene administravit*, pleaded by an executor, if it be proved that he hath goods in his hands which were the testator's, he may give in evidence that he hath paid to the value of his own money, and need not plead it specially; for when an executor before the action hath paid the money to equal degree with that demanded by the plaintiff, he may plead fully administered generally, and give the special matter in evidence. 2 Litt. Abr. 330.

PLENILUNIUM, compounded of *plenus*, and *luna*, in *Astronomy*, that phasis or state of the moon, popularly called the *full moon*.

PLENIPOTENTIARY, compounded of *plenus*, *full*, and *potentia*, *power*, a person who has full power and commission to do any thing.

The word is chiefly understood of the ministers or ambassadors sent from princes or states to treat of peace, marriages, and other important matters.

The first thing done in conferences of peace, is, to examine the power of the *plenipotentiaries*.

PLENITUDE, *plenitudo*, the quality of a thing that is full, or that fills another.

In physic, it is chiefly used for a redundancy of blood and humours.

Physicians reckon two kinds of *plenitude*. The one called *ad vires*, when the abundance of the blood oppresses the patient's strength.

The other *ad vasa*, when it fills the vessels too much; swelling them to a degree of bursting.

PLENNA, a word used by some writers to express any mucous humour.

PLENUM, in *Physics*, a term used to signify that state of things, wherein every part of space, or extension, is supposed to be full of matter.

It is used in opposition to a *vacuum*, which is a space supposed devoid of all matter.

The CARTESIANS adhere firmly to the doctrine of an absolute *plenum*. This they do on this principle, that the essence of matter consists in extension; from whence, indeed, the consequence is very easy, that wherever there is space or extension, there is also matter.

But this principle we have shewn to be false; and, therefore, the consequence drawn from it falls to the ground. See MATTER.

But that there is a real vacuum, in the nature of things, is likewise demonstrated by arguments *à posteriori*, under VACUUM.

PLEONASM, *pleonasmus*, formed from πλεονάζειν, q. d. *superabundancy*, in *Rhetoric*, a figure of speech, whereby we make use of words, seemingly needless or superfluous, in order to express a thought with the greater force and energy.

Such is, *I saw it with my own eyes*; or, *he heard it with his own ears*, &c.

The *pleonasm* is called by the Latins *redundantia*.

Pleonasm, by grammarians, is usually defined a fault in discourse, wherein we say more than is necessary.

M. Vaugelas will not allow the phrase, *I saw it with my own eyes*, to be a *pleonasm*; inasmuch as there are no superfluous words in it; none but what are necessary to give a stronger assurance of the thing affirmed. It is sufficient that one of the phrases say somewhat more than the other, to avoid the imputation of a *pleonasm*.

In effect, though we give the name *pleonasm* to any thing that is not necessary, or that enters the discourse independently of the sense or construction, yet there are frequently words which, in that view, would be pertinent, and even are used to good purpose, to give a greater force or grace to discourse, and to ascertain the truth of what is said.

He spoke with his mouth, is a *pleonasm* in English; it is none in Latin: Virgil says, *fit ore locutus*. Some French authors deny *unir ensemble*, *to unite together*, to be a *pleonasm*.

PLEROSIS, a word used by the old Greeks to express the repletion

repletion or restoring the body to its natural state, after it has been emaciated by sickness.

PLEROTICS, Πληρωτικα, formed from πληρω, *I fill*, in *Medicine*, a kind of remedies, otherwise called INCARNATIVES, and EPULOTICS.

PLESMONE, a word used by the ancients to signify plenitude or satiety.

PLESSYA, in *Ichthyology*, a name given by Bellonius to a fresh water fish of the leather-mouthed kind, appearing to be no way essentially different from the more common kind of cucullus, called by authors *cucullus tertium genus*.

PLETHORA, Πληθωρη, in *Medicine*, such an abundance of any good and laudable humour, as proves hurtful to the animal functions.

Plethora is chiefly understood of the blood, though sometimes of the other humours.

The *plethora* is the consequence of a good chylification, sanguification, &c. attended with a too sparing discharge by perspiration, &c.

It is usually described either as *ad vires*, or *ad vasa*. See PLENITUDE.

The *plethora* is chiefly produced in a body whose organs of digestion are strong, blood-vessels lax, diet full of good juice, temperament sanguine, mind at ease and indolent, of a middle age, and in a moist air. It renders heat and motion unequal; it stretches the great vessels, and compresses the smaller. And hence slippery and heavinesses, and on the least occasion ruptures in the vessels, suffocations, &c.

Dr. Freind makes the catamenia, or MENSES, the mere result of a *plethora*.

Medical writers now usually distinguish four kinds of a *plethora*. 1. The simple *plethora*, which is that state of the body in which the blood is too abundant in quantity, but in as yet of no bad quality. 2. The cacochymous *plethora*, which is that where the blood is abundant in quantity, and at the same time is subject to a too great tenderness or some other deficacy. 3. The *plethora ad vasa*, wherein the blood, from its over great quantity, renders the vessels turgid, without any further ill effect. And, 4. The *plethora ad vires*, in which there is joined to too great a plenitude of the vessels, a lassitude and torpor, or numbness of the limbs.

The signs of a *plethora* are, 1. A florid constitution of the body. 2. A tolerable use of the non-naturals, a good appetite to food, and a sound sleep: this is the case while the *plethora* is simple and unmoved, but when any commotion happens from without, the signs are inquietude at night, dreams of bleeding, and of wounds from swords or other weapons, robust looks in the face, and a general turgescence of the vessels, a heaviness of the limbs, an inaptitude to motion, and difficulty of breathing, a vertiginous disorder of the head, a sense of a pricking or tingling in the flesh from the slightest heat, an easy heating of the body from the weather, a moisture of the eyes, and in hysteric women a sensation as if a piece of cold ice were suddenly laid on some part of the head.

PLETHORA *getbus and full of it*, are, 1. People of sedentary lives, who live high. 2. The younger rather than persons more advanced in years. 3. The female sex rather than the men. 4. All persons who have been accustomed to large evacuations, and have hastily suppressed them. And, 5. Those persons who have suddenly changed a life of labour or exercise to a sedentary one, without making the necessary changes in the non-naturals.

PLETHORA, *prognostics from it*. 1. *Plethoric* persons are more subject to diseases in general than others. 2. They are particularly subject to hæmorrhages, inflammations, and acute fevers. 3. The lighter diseases coming upon persons of a *plethoric* habit, are usually more stubborn and dangerous than on others. 4. The *plethora* itself can scarcely be called a disease, but it is the parent of many diseases. Chronic diseases are with more difficulty cured in *plethoric* patients than in others, because they are always averse to exercise. 6. A *plethoric* habit, disturbed by violent motion, by passions of the mind, or by stimulating medicines, is capable of producing very terrible consequences. 7. The diseases arising from a *plethora*, from stopping some accustomed evacuation, are with difficulty cured; and *plethoras* are more efficaciously relieved by natural hæmorrhages than by any artificial means.

PLETHORA, *method of cure in*. A simple *plethora* is easily removed by bleeding and gentle exercise, and by a more spare diet; to these may be added, gentle purging once a month. The *plethora* with a cacochymy requires gentle purging, bleeding, and cupping, diaphoretics and diuretics. If a violent commotion of the blood happen with a *plethora*, temperance is to be still prescribed, then the use of nitre and crabs eyes saturated with lemon juice, and other cooling and alterative remedies. Juncker's Conspect. Medic. p. 4.

PLETHRON, a Grecian measure, by some said to contain 1444, by others 10,000 square feet. Arbuthnot.

PLEVIN, *plevina*, in *Law*, a warrant or assurance; the same with pledge. See PLEDGE, REPLEVIN, &c.

PLEURA, Πλευρα, derived from πλεω, which, primarily, signifies *fide*, in *Anatomy*, a membrane which lines the inside of the cavity of the breast, and includes all the parts contained therein, being of the same figure and extent as the thorax itself, and of the same substance with the PERITONÆUM. The Latins call it *succingens*.

It is of a very fine texture, and plentifully stored with blood-vessels and nerves; and made up of an inner true membranous lamina, and a cellular substance on the outside, which is a production of the lamina. The cellular portion goes quite round the inner surface of the thorax, but the membranous portion is disposed in a different manner. Each side of the thorax has its particular *pleura*, entirely distinct from the other, and forming, as it were, two great bladders, situated laterally with respect to each other in the great cavity of the breast, in such a manner as to form a double septum or partition running between the vertebræ and the sternum, their other sides adhering to the ribs and diaphragm. This particular duplicature of the two *pleuræ* is termed MEDIASTINUM. The cellular portion of the *pleura* connects the membranous portion to the sternum, ribs, and muscles; to the diaphragm, pericardium, thymus, and vessels, and to every part that lies near the convex side of the membranous portions of the *pleuræ*. It likewise insinuates itself between the laminæ, of the duplicature of which the mediastinum is formed, and unites them together. It even penetrates the muscles, and communicates with the cellular substance in their interstices, all the way to the membrana adiposa on the external convex side of the thorax. The inner surface of the *pleura* is moistened by a lymphatic serosity, which transudes through the pores of the membranous portion; and this fluid is said to be secreted by imperceptible glands, the existence of which has not yet been demonstrated. The arteries and veins of the *pleuræ* are chiefly ramifications of the intercostals, and also of the mammariæ internæ and diaphragmaticæ. The nerves are ramifications of the true intercostales, called otherwise costales and dorsales. Winslow.

The use of the *pleura* is to defend the inside of the thorax, and to render it smooth, that the lungs may not be hurt in their motion.

PLEURISY, *pleuresis*, *pleuritis*, πλευρίτις, in *Medicine*, a violent pain in the side, attended with an acute fever, a cough, and a difficulty of breathing.

The *pleurisy* arises from an inflammation of some part of the pleura, to which is frequently joined that of the exterior and superficial part of the lungs.

This inflammation seizes any part of the integuments of the thorax, viz. either the pleura or mediastinum; and, the more, the pricking pain may be felt in any part of the thorax; but the place it most ordinarily infests is the side; sometimes the right, sometimes the left; sometimes higher, sometimes lower.

The *pleurisy* sometimes succeeds another fever, occasioned by a precipitation of the febrile matter upon the pleura.

When it rises to an impostume, it is called an EMPYEMA. When it happens in the mediastinum, or diaphragma, it is called PARAPHRENITIS.

The *pleurisy* and peripneumony have some resemblance in their general symptoms, and are thence sometimes mistaken one for the other. They are, however, extremely different in their place of origin, as well as in their several symptoms; the *pleurisy* being a stasis of blood in the *pleura*, and the *peripneumony* a stasis of the same fluid in the lungs. They are both attended with an acute, continuous, and inflammatory fever, by means of which nature is labouring to break through the obstructions made by the stasis of the blood in those parts.

The spurious *pleurisy* is to be carefully distinguished from these two diseases. In the true *pleurisy*, or *peripneumony*, a pain is felt either about or a little below the nipple; but the spurious *pleurisy* generally shews itself higher, usually about the clavicle; the pain is more external, and usually affects the muscles between the ribs. In the genuine diseases the pains are equal and regular, answering to the pulse; in the spurious *pleurisy* they are vague, and wholly irregular. In the true, they are also continual; but in the spurious, they have frequent intermissions and remissions. The true have always a cough attending them, usually attended with a spitting of coloured matter, at first thin, afterwards prolix, and often streaked with blood, though sometimes with little or no spitting, which has given occasion for distinguishing the true *pleurisy* into the moist and dry; but the spurious often has no cough at all attending it, or if it has, it is either dry, or there

is no difference seen in the matter voided by spitting. The true has always an acute continuous fever, which attacks the patient at first with a shivering; the spurious either has no fever at all with it, or it is at the utmost a slight and irregular one. The pulse is quick, and there is a difficulty of lying on the affected side, which does not always occur in the true *pleurisy*.

The true diseases do not terminate in less than seven days; the others much sooner. The true usually attack young people; the spurious are common to young and old. The bastard or spurious *pleurisy* generally goes off by keeping warm for a few days, drinking plenty of diluting liquors, and observing a proper regimen. In some cases, indeed, it proves more obstinate, and requires bleeding, cupping, and scarification of the part affected. These operations, with the use of nitrous and other cooling medicines, seldom fail to effect a cure. The difference between the true and spurious diseases is determined by the observation of these symptoms; but it yet remains to distinguish justly the true diseases from one another. This is done by the following observations.

The *pleurisy* is a very rare disease; and the *peripneumony* a very common one; but this is exactly contrary to the common opinion, from these diseases being too generally confounded with, and mistaken for, one another.

In a *peripneumony*, a spitting of blood usually happens about the close of the second day: this is a primary symptom in a *peripneumony*, but is usually erroneously attributed to a *pleurisy*, though reason shews how easily such a spitting may happen from an inflammation of the lungs; and it is very different to conceive how it should happen so readily from an inflammation of a part so remote from having any communication with the organs of expectoration as the pleura.

In the *peripneumony*, the pain extends itself further, affecting the whole breast, whereas in the *pleurisy* it is rather fixed to the right side, and felt a little below the breast. These are the symptoms by which these diseases are distinguished from one another, and the use of the distinction is principally this, that in the *pleurisy* the application of external remedies often is of great service, whereas it is of no effect in the other case, though the mistake is of no great consequence in this respect, as the applications in the *peripneumony* can do no harm; but in an unhappy termination of these diseases by suppuration, the distinction becomes of some consequence; since, in the *pleurisy*, the matter may be evacuated by a paracentesis, or the letting in a canula; which in the *peripneumony* can by no means be done, unless in such an accidental case that the disease terminates in an external *vomica pulmonum*; then indeed the matter being discharged from the abscess into the cavity of the thorax, may be let out in the same manner as in the suppurated *pleurisy*; but this is a case that does not occur in an age.

The usual opinion of medical writers, in regard to this case, is, that the *peripneumony* is always a disorder affecting only the external surface of the lungs; and they observe, that even its name expresses this, the signification of it being a dilemperature spreading round about the lungs: this, however, is not agreeable to observation or experience; for in dissections of bodies that have died of this disease, the very internal part of the lungs is always found affected; and indeed if the surface only were so, it is not easy to conceive how the spitting of blood should come on so soon as the second day.

Signs of these diseases. These are in general common to both, and are the following: a vertiginous disorder of the head usually precedes all the other symptoms; this is succeeded by a shivering and chillnefs all over the body; this increases by degrees, and usually brings on with it cardialgias, naufea, and anxieties: after this there comes on a very remarkable heat, with very intenfe thirft, and a violent pain in the head; this is accompanied with a ftraitnefs of the breaft, and difficulty of refpiration; and the patient feels a violent and fevere pricking pain in one of the fides amongft the *ribs*, which fometimes extends towards the back-bone, fometimes towards the fore-part of the breaft, and at other times towards the fhoulder blades: this pain becomes continual, is always greatly exafperated by the cough that attends the difeafe, and is generally moft violent when the patient draws in his breath. The urine in the firft days is red, and after a few days more it becomes turbid, when it has ftood to be cold; and finally depofits a thick pale-red fediment. The pulfe in the *pleurify* is commonly quick and hard; and if blood be let, it is covered with a tough cruft or buffy coat. Baglivi remarks, that *pleurifies* are frequently occult, and gives the method of difcovering them: make the patient lie on his right or left fide, and bid him breathe ftrongly, and cough; if he feels any pain or heavinefs after it, he is certainly pleuritic. The fame author adds, that a hard pulfe is a certain attendant of the *pleurify*.

Perfons fubject to them. Thefe are difeafes not equally common to all ages, but they principally affect young and labouring people; they are moft frequent in the beginning of the fpring feafon, and moftly affect fuch as are of a fanguine plethoric habit. Perfons who have been fubject to bleeding at the nofe, but have been for fome time free from returns of them, often fall into thefe difeafes; and in general men are much more fubject to them than women.

Caufes of them. Thefe difeafes are brought on by any thing that gives a violent commotion to the blood, fuch as immoderate exercife, the abufe of fpirituous liquors, and violent fits of anger. The fuddenly cooling the body when very hot, by drinking cold liquors, fleeping on damp ground, wet clothes, and expofing the body to cold water or air in this ftate, has alfo often occafioned them, by fhutting the pores and forcing the blood inwards. The neglect of habitual bleedings, the ftoppage of ufual evacuations, and the ftriking in of any eruption, may alfo occafion them; and they have been fometimes occafioned by blows, or other external injuries on the breaft, and by endeavouring to lift great weights.

Prognoftics in them. All inflammatory fevers are dangerous, but the *pleurify* and *peripneumony*, when they attack young perfons, or fuch as are under thirty years of age, are attended with the leaft danger of any, provided that they are properly treated. When they affect perfons advanced in years, they ufually prove very dangerous, in fpite of all the care and caution with which they can be treated.

When they have been treated in a judicious manner, they ufually go off on the feventh, or at the utmoft the eleventh day, in copious fweats, which come on of themfelves; after this crifis, the pulfe in a very little time returns to its natural ftate, the violent heat goes off, and the ftrength, appetite, and fleep, return. When they go beyond the days of their crifis, which is often the cafe in old people, they then become very dangerous. If the urine is obferved to be turbid before the fourth day, and afterwards depofits a fediment, and the reft remain clear at the top, there is great hope that the difeafe will terminate happily, on the critical day, by a fweat. When a yellowifh matter is thrown up by coughing, and is neither very vifcid nor frothy, and particularly when in a *peripneumony* it is ftreaked with blood, there is great reafon to expect that the difeafe will go happily off; but, on the contrary, when the patient cannot fpit at all, and the urine continues crude, there is great reafon to fear the difeafe will have a fatal period.

Finally, when a difcuffion and refolution of the ftafis cannot be effected by nature, or obtained by art, a corruption and fuppuration follow, and often an ulcerous difpofition of the lungs, or true phthifis, is the confequence.

Method of cure. The bowels are to be kept gently lax during the whole courfe of the difeafe; but no irritating medicines muft by any means be given to promote this. For this purpofe, a clyfter of thin water-gruel, or of barley-water, in which a handful of mallows, or any other emollient vegetable has been boiled, may be daily adminiftered. When there is a remarkable plethora with a narrownefs of the breaft, and a fenfible ftuffing up of the lungs, then bleeding is neceffary; but a fmall quantity only fhould be taken away, and the fame repeated the next day or oftener, if the fame fymptoms continue to require it; always after bleeding the patient muft take fome gently diaphoretic medicines, and drink plentifully of water and weak liquors. In the ufual and more common cafes, bleeding, according to fome, is not neceffary in thefe difeafes, though fo greatly recommended by others. Every day before noon it is proper to give two doles of the mixtura fimplex, or fome other fuch temperate diaphoretic, with large draughts of warm liquors; and in the afternoon the antifebrile powders of nitre, diaphoretic antimony, crabs eyes fated with lemon juice fhould be given; and emulfions are alfo very proper, made of fweet almonds and barley water, or of the feeds of carduus Marise. When thefe medicines have been given for fome days, if the pain continues ftill violent, the tincture of caftorilla muft be taken; and in cafes of the *pleurify*, cloths four or more times doubled and wetted in camphorated fpirit of wine, are to be applied to the part. Fomentations may be prepared by boiling a handful of the flowers of elder, chamomile, and common mallows, or any other foft vegetables, in a proper quantity of water. The herbs may be either put into a flannel bag, and applied warm to the fide, or flannels dipped in the decoction muft be fucceffively ufed in the fame manner. The fide may alfo be frequently rubbed with a little of the volatile liniment; leaves of various plants, and efpecially young cabbage leaves, may be applied warm to the fide with advantage. Plaifters may alfo be applied occafionally, but they muft not be fuffered to remain on

too

too long, lest they stop respiration; an equal regimen and perfect quietness are to be observed during the whole time of the disease; but particularly on the critical days, on which nature must be by no means ruffled or disturbed.

The diet ought to be cool, slender, and diluting; the drink may be sweet whey, an infusion of pectoral and balsamic vegetables, barley water, with a little honey or currant jelly mixed with it, or the decoction of figs, raisins, barley, &c. These liquors should be drank often and in small quantities. Every thing the patient takes should be a little warm.

Authors differ greatly in their opinions about bleeding in this disease: some judge it absolutely necessary in all cases; and others wholly reject it in all. Etmuller observed, that bleeding in these diseases always gave the ftalis a tendency to suppuration, and much recommends sudorifics in the *pleurisy*; others are of opinion, that it is to be done, or omitted, according to the peculiar indications in the case; and some throw aside all the dissolvent and discutient medicines, and rely on the volatile salts alone for the promoting sweats, and accomplishing the cure by that means alone, only observing, that if the disease will not yield to these, bleeding is to be added.

Others again contend, that it is a rash attempt to endeavour to discuss the ftalis already formed, by hot medicines, which expand the blood, and seem calculated only to add to it; and that the natural ftate of the disease does not indicate bleeding, though the urgency of certain symptoms, such as ftrictness of the breaft and infarctions of the lungs, in perfons of plethoric habits, may render it neceffary and beneficial.

Perfons of very plethoric habits, who have died of these distempers, on diffection, have been found to have one side of the lungs to ftuffed up with blood, that it would sink in water; and unqueftionably in such cases bleeding is neceffary.

Sydenham's method of curing by large and often repeated bleedings, and the ufe of gentle expectorants, has been found, fays Junker, very dangerous in its effects, and seems the only reproachable thing in the works of that excellent writer. And he adds, though Riverius gives an instance of a person cured of a *pleurify* in a few hours, by bleeding alone, the account does not seem wholly to be depended upon; for some circumftances in the relation seem to fhew, that the disease was not properly either a *pleurify*, or a *peripneumony*, but an inflammation of the liver or ftomach.

Nevertheless, moft medical writers have recommended bleeding as soon as poffible, and large quantities at once, in the beginning of a *pleurify*, in preference to ftall repeated bleedings. An adult, fays Dr. Buchan, may lofe twelve or fourteen ounces of blood as foon as it is certainly known that he is feized with a *pleurify*. If the ftitch and other violent symptoms continue, eight or nine ounces more of blood may be taken away at the diftance of twelve or eighteen hours. When the symptoms do not abate, and the blood manifefts a ftrong buffy coat, a third and even a fourth bleeding may be neceffary. But the operation of bleeding is feldom neceffary after the third or fourth day of the fever, and ought not to be performed unless in very urgent circumftances. Topical bleeding by leeches, or cupping, has a very good effect. If the ftitch continues after repeated bleedings, fomentations, &c. a blittering plafter muft be laid on the parts affected, and fuffered to remain for two days. Some people recommend the flowers of the common red poppies in these cases, as a fpecific remedy; but Etmuller allows them no such quality, but fays they act in this case merely as a gentle opiate and anodyne; a sort of medicines very dangerous in these cases.

The seeds of carduus marise, or the milk thiftle, are also by some recommended as fpecifics: it is very evident that they mitigate the pain; but the fever will always continue to its regular period on the seventh day.

Expectorating medicines, in general, are of no ufe in these cases, only if the fpitting of a bloody matter do not succeed fufficiently by the fourth day, it may be neceffary to give a dose or two of something of this kind; and to this purpose a decoction of hyffop is preferred by many before all other medicines.

The fpitting may be promoted by taking two table fpoonfuls of a mixture of an ounce of the oxymel or vinegar of squills with fix ounces of the *pectoral* DECOCTION: or the *julep* EMULSION may be administered; or if oily medicines are naufeous, two table-fpoonfuls of the folution of gum ammoniac in barley water may be given three or four times a day.

Nitre is to be given boldly for the four firft days; but after this, if the disease go on regularly, it is to be given in smaller quantities, and not oftener than twice in a day. All oily and fatty fubftances are to be excluded from external ufe, but camphor in any form is found to do fervice.

When the patient does not perfpire, and has a burning heat on his fkin, and diffolves little water, two drams of purified nitre may be rubbed with five or fix grains of camphor in a mortar, and the whole divided into fix doses, one of which may be taken every five or fix hours in the patients common drink. Dr. Buchan mentions another medicine, which he fays, fome reckon almoft a fpecific in the *pleurify*; viz. the decoction of the fcutch rattle-fnake-root. After bleeding and other evacuations, the patient may take two, three, or four table-fpoonfuls of this decoction, as his ftomach can bear it, three or four times a day. If it occafions vomiting, the quantity may be leffened or mixed with fimple cinnamon-water.

Opiates in these cases are dangerous, for as there is in all of them a tenacity of the blood, this ftate of it requires concuffion, refolution, and excretion, but opiates effect the exact contrary of all these. Caftorilla properly given, will almoft always mitigate the pain; and when that fails of its effect, it is certain that opiates cannot procure it, but muft inevitably do harm. Junck. Conf. Med. p. 297, and feq. Buchan's Dom. Med. ch. 16.

Mr. Du Hamel found the polygala vulgaris of fervice in promoting expectoration in *pleurifies*. Med. de l'Acad. Science. 739.

PLEUROCYSTUS, in *Natural Hiftory*, the name of one of the general arrangements of the echini marini.

The word is derived from the Greek πλευρον, *the fide*, and κυστις, *the anus*.

The echini of this division are diftinguifhed from the others, by having their anus neither on the fummit, nor in any part of the base, but in fome part of the fuperficies of one of the fides.

PLEURONECTES, in *Ichthyology*, the name of a genus of fifhes of the malacopterygious kind, the characters of which are these: the branchioftege membrane, on each fide, contains fix bones of a cylindric figure; and in the middle between these, but lower down, there are two others joined together at the end, but these are fcarce confpicuous. Both the eyes are placed in one fide of the head; in fome they are in the right fide, and in others in the left; the eyes are covered with a fkin; one fide of the fifh is always white, the other is fpotted or obfcure.

Of these fifh there are fome which have a very fhort fpine at the anus, and the eyes ufually on the right fide. The fpecies of this fort, enumerated by Artedi, are seven. The other species of the *pleuronectes* have their eyes on the left fide of the head, and have no fpine, or fcarce any at the anus. Of these Artedi enumerates three fpecies.

The name is of Greek origin, and is derived from the words πλευρα, *the fide*, and νηκω, *a fwimmer*; and expreffes the peculiar and diftinctive character of these fifhes; which is, that they all fwim on one fide, not as other fifhes.

In the Linnæan fyftem, this is a genus of the *thoracici*, comprehending feventeen fpecies, as the *hippoglossus*, *platessa*, *flounder*, *dab*, *fole*, *pearl*, *turbot*, &c.

PLEUROPNEUMONY, a name given by medical writers to a disease approaching to, and partaking of the nature of both the PLEURISY and PERIPNEUMONY.

PLEURORTHINOPŒA, a term ufed by medical writers to express that kind of pleurify in which the patient cannot breathe, unless in an erect posture.

PLEXUS, in *Anatomy*, a name common to feveral parts in the body, confifting of bundles of little veffels interwoven in form of net-work.

The nerves, in their progrefs, form feveral *plexuses*; efpecially the par vagum, or eighth pair, the intercoftals, and the fifth.

The par vagum, at its interfection with the intercoftal nerve, forms the *plexus ganglioformis* fuperior and inferior. A branch of this nerve joining near the heart, with others from the intercoftals, forms the *plexus cardiacus fuperior*. A little further it fends off feveral branches, which, reuniting, form the *plexus pulmonalis*. In each trunk of the intercoftal, before it arrives at the thorax, are two *plexus ganglioformes*, called *plexus cervicales*. When arrived in the thorax, it receives three or four twigs from the vertebral nerves, together with which it conftitutes the *plexus intercoftalis*; whence, defcending into the abdomen, it forms that famous piece of net-work, called on the right fide *plexus hepaticus*; and on the left, *plexus fplenicus*. From the hepatic *plexus* arife a number of branches, proceeding fome to the liver, others to the pancreas, others to the capfula of Glifon, and other larger ones to the right kidney. The fplenic *plexus* fends out branches to the left part of the ventricle and pancreas, the fplen, the left atrabiliary capfula, and left kidney. Laftly, feveral branches both from the hepatic and fplenic *plexus*, paffing along the mefenteric arteries, efpecially the upper, to which they ferve as a kind of cover, form the mefenteric *plexus*, which bears fome refemblance to a fun, from the circumference whereof proceed feveral

little branches or threads, in manner of rays, continued thence to the intestine, though still accompanying the arteries.

PLEXUS *choroides*. See CHOROIDES.

It is sometimes, also, called *plexus reticularis*, from its net-like structure.

PLICA *Polonica*, in *Medicine*, a disease of the hair, almost peculiar to Poland, though there are instances of it in Hungaria, Alsatia, Switzerland, &c.

Writers are not agreed as to the history of the origin of this disease. Some assert that it was not known before the year 1564; others, with the greatest probability, fix its epocha to the year 1287, when the Tartars corrupted the waters of the country: whilst others apprehend, that it has existed from time immemorial.

The *plica* is a severe, malignant, and dangerous disease, wherein the hair of the head is matted and glued together beyond all possibility of being extricated; and is attended with a grievous disorder of all the limbs of the body; and, before the hair becomes complicated, a violent pain; a sweat usually attending it.

An unseasonable cutting off the hair, in this case, is dangerous; nor is there any proper and adequate remedy for the disease yet discovered.

In Poland and Lithuania, this disorder is endemial, and well known; it consists in a preternatural bulk of the hair, which being firmly conglutinated and wrapped up in inextricable knots, affords a very monstrous and unseemly spectacle. When this is cut, blood is discharged from it, the head is racked with pain, the sight impaired, and the patient's life frequently endangered. This misfortune is principally incident to the Jews who live in those countries. Though it seems difficult to account for this disorder, and assign its true causes, we shall, nevertheless, make an attempt of this kind.

What therefore contributes not a little to its production, is the sordid and nasty manner of life to which these people are addicted, for they rarely comb their hair, sleep in low moist rooms, and drink large quantities of brandy. The waters, also, concur and assist in the generation of this disorder. Henric Gehema, in Epist. ad Bontekoe de *Plica* Polonica, is justly of opinion, that the causes of this disease are lodged in some particular waters of Poland, which if either drank, or used for washing the body, produce the *plica*. This he confirms by the fate of two soldiers, who, when intending to wash their bodies, had scarce immersed their heads in the water of a certain pond, before their hairs were contracted into many folds. Beside these causes, we suppose an hereditary fault conveyed from the parents, &c. which consists in too great a bulk of the pores, and bulbous hairs under the skin of the head. Hence the thick and glutinous nutritious juice, produced by their coarse aliments, and impure waters, is, by the heat excited by their drinking brandy, forced into the cavities of the hairs, and sweating through their pores, produces this terrible disorder. Hoffman. de Morb. cert. Reg. propr.

From the symptoms that precede and accompany the *plica*, it seems to be a species of malignant fever or acute scurvy, whose distinguishing symptom or crisis is a complication of the hair. Some authors have pretended, that the earth mosi, hence called *plicaria*, used externally in fomentation, and internally in decoction, is a specific in this disease. Others have attributed extraordinary virtues to mercury.

PLICARIA, in *Botany*, a name used by some for the club-mosi.

PLICATED *leaf*, among *Botanists*. See LEAF.

PLIGHT, in our *Old Law-Books*, a term which signifies the estate, with the quality of the land; though, sometimes, it extends also to the rent-charge, and the possibility of a dower. Coke's Inst. fol. 221.

PLINIA, in *Botany*, the name of a genus of plants of the *polyandria monogynia* class, described by Plumier and Linnæus, the characters of which are these: the empalement is divided into five segments; the flower consists of five petals; the stamina are numerous filaments, very slender, and of the length of the flower; the antheræ are small; the germen of the pistil is small; the style is subulated, and of the length of the stamina; the stigma is simple; the fruit is a large globose berry, of a striated or sulcated surface, containing only one cell, in which is a very large, smooth, and globose seed. There is one species.

PLINTH, from πλινθος, *brick*, in *Architecture*, a flat square member, in form of a brick: sometimes, also called the slipper. See *Tab. Archit. fig.* 25, N° 3.

The *plinth* is used as the foot, or foundation of columns: being that flat square table, under the mouldings of the base and pedestal, at the bottom of the whole order; seeming to have been originally intended to keep the bottom of the primitive wooden pillars from rotting.

The *plinth* is also called the *tile* or BRICK.

Vitruvius also calls the Tuscan abacus, *plinthus*, from its resembling a square brick.

PLINTH *of a statue*, &c. is a base or stand, either flat, round, or square, serving to support a statue, &c.

PLINTH *of a wall*, is a term for two or three rows of bricks advancing out from the wall; or in the general, for any flat high moulding, serving in a front wall to mark the floors; or to sustain the eaves of a wall, and the larmier of a chimney.

PLINTHITIS, a kind of alum found in some of the islands of the Archipelago, and called also *plumbitis*, from its usually being found in thin cakes.

PLINTHIUM, a name given by the ancients to a machine invented for the making extension of dislocated or fractured limbs. Oribasius describes several kinds.

PLITE *of lands*, in our *Old Writers*, seems to be an ancient measure, as a yard or ell, at this time: it is mentioned in the stat. 3 Ed. IV. cap. 5.

PLOCE, in *Rhetoric*, a figure whereby a word is repeated, by way of emphasis; in such manner, as not only to express the subject, but some particular character or property of it.

Cruelty! yes, cruelty beyond all example. His wife's a wife indeed! So Cicero says, Young Cato wants experience, but yet he is Cato.

PLOK-PENIN, a term used in the public sales at Amsterdam for a little sum given by the last bidder.

The *plok-penin* is a kind of earnest, whereby it is signified, that the commodity is adjudged to him.

The *plok-penin* differs according to the quality of the commodity, and the price of the lot. Sometimes it is arbitrary, and depends on the pleasure of the buyer; and, sometimes, it is regulated by the ordinances of the burgomasters.

PLOMO, *in Metallurgy*, a name given by the Spaniards, who have the care of the silver mines, to the ore of that metal, when it is found adhering to the surface of stones, and incrusting their cracks and cavities in the form of small and loose grains of gunpowder. Though these grains be but few in number, and the rest of the stone have no silver in it, yet they are always very happy in meeting with it, as it is a certain token that there is a very rich vein somewhere in the neighbourhood. And if in digging forwards they still meet with these grains, or the *plomo* in greater quantity, it is a certain sign that they are getting more and more near the good vein.

PLONKETS, in our *Old Writers*, a kind of coarse woollen cloth. 1 Rich. III, cap. 8.

PLOT, or PLOTT, in *Gardening*. See GRASS-*plot*, &c.

PLOT, in *Dramatic Poetry*, the FABLE of a tragedy or comedy; or the ACTION represented therein.

PLOT, is more particularly used for the knot or intrigue, which makes the difficulty and embarrass of a piece.

The unravelling puts an end to the *plot*.

PLOT, in *Surveying*, the plan or draught, of any parcel of ground, e. gr. a field, farm, or manor, surveyed with an instrument, and laid down in the proper figure and dimensions. See PLOTTING.

PLOTTING, among *Surveyors*, the art of describing or laying down on paper, &c. the several angles and lines of a tract of ground surveyed by a theodolite, or the like instrument, and a chain.

In surveying with the plane-table, the *plotting* is needless; the several angles and distances being laid down on the spot as fast as they are taken.

But, in working with the theodolite, semicircle, or circumferentor, the angles are taken in degrees; and the distances in chains and links. So that there remains a subsequent operation, to reduce those numbers into lines; and so to form a draught, plan, or map. The operation is called *plotting*.

Plotting, then, is performed by means of two instruments, the protractor and *plotting-scale*. By the first, the several angles observed in the field with a theodolite, or the like, and entered down in degrees in the field-book, are protracted on paper in their just quantity.

By the latter, the several distances measured with the chain, and entered down, in like manner, in the field-book, are laid down in their just proportion.

Under the articles *protractor* and *plotting-scale*, is found, severally, the use of those respective instruments in the laying down of angles and distances; we shall here give their use conjointly, in the *plotting* of a field, surveyed either with the circumferentor, or theodolite.

PLOTTING, *method of, from the circumferentor*. Suppose an inclosure, e. gr. ABCDEFGHK (*Tab. Survey. fig.* 8) to have been surveyed, and the several angles, as taken by a circumferentor in going round the field, and the distances, as measured by a chain, to be found entered in the field-book, as in the following table:

	Deg.	Min.	Chn.	Link.		Deg.	Min.	Chn.	Link.
A	191	00	10	75	F	324	30	7	54
B	207	00	6	83	G	98	30	7	54
C	246	30	7	82	H	71	00	7	78
D	325	00	6	96	K	161	30	8	22
E	12	24	9	71					

1. On a paper of the proper dimensions, as L M N O *(Tab.* III. *Survey. fig.* 43.) draw a number of parallel and equidistant lines, representing meridians, expressed in dotted lines. Their use is, to direct the position of the protractor; the diameter whereof muſt always be laid either upon one of them, or parallel thereto; the ſemicircular limb downwards for angles greater than 180°, and upwards for thoſe leſs than 180°.

The paper being thus prepared, aſſume a point on ſome meridian, as A, whereon lay the centre of the protractor, and the diameter along the line. Conſult the field-book for the firſt angle, i. e. for the degree cut by the needle at A, which the table gives you 191°.

Now, ſince 191° is more than a ſemicircle or 180°, the ſemicircle of the protractor is to be laid downwards; whence, keeping it to the point with the *protracting pin*, make a mark againſt 191; through which mark, from A, draw an indefinite line A *b*.

The firſt angle thus protracted, again conſult the book, for the length of the firſt line A B. This you find 10 chains 75 links. From a convenient ſcale therefore, on the *plotting ſcale*, take the extent of 10 chains 75 links between the compaſſes; and fetting one point in A, mark where the other falls in the line A *b*, which ſuppoſe in B: draw therefore the full line A B, for the firſt ſide of the incloſure.

Proceed then to the ſecond angle; and, laying the centre of the protractor on the point B, with the diameter as before directed, make a mark, as *c*, againſt 207°, the degrees cut at B; and draw the indefinite line B *c*. On this line, from the *plotting-ſcale*, as before, ſet off the length of your ſecond line, viz. 6 chains 83 links; which extending from B to the point C, draw the line B C, for the ſecond ſide.

Proceed now to the third angle or ſtation: lay then the centre of the protractor, as before, on the point C; make a mark, as *d*, againſt the number of degrees, cut at C, viz. 246° 30′: draw the indefinite line C *d*, and thereon ſet off the third diſtance, viz. 7 chains 82 links; which terminating, e. gr. at D, draw the full line C D, for the third ſide.

Proceed now on the fourth angle D; and, laying the centre of the protractor over the point D, againſt 325°, the degree cut by the needle, make a mark *e*; draw the occult line D *e*, and thereon ſet off the diſtance 6 chains 96 links; which terminating in E, draw D E for the fourth line: and proceed to the fifth angle, viz. E.

Here the degrees, cut by the needle, being 12° 24′ (which is leſs than a ſemicircle) the centre of the protractor muſt be laid on the point E, and the diameter on the meridian, with the ſemicircular limb turned upwards. In this ſituation make a mark as before, againſt the number of degrees, viz. 12° 24′, cut by the needle at E; draw the line E *f*, on which ſet off the fifth diſtance, viz. 9 chains 71 links; which extending from E to F, draw the full line E F, for the fifth ſide of the incloſure.

After the ſame manner proceed orderly to the angles F, G, H, and K; then placing the protractor, making marks againſt the reſpective degrees, drawing indefinite lines, and ſetting off the reſpective diſtances, as above, you will have the *plot* of the whole incloſure, A B C, &c. Such is the general method of *plotting* from this inſtrument; but it muſt be obſerved, that, in this proceſs, the ſtationary lines, i. e. the lines wherein the circumferentor is placed to take the angles, and wherein the chain is run to meaſure the diſtances, are, properly, the lines here *plotted*. When, therefore, in ſurveying, the ſtationary lines are at any diſtance from the fence or boundaries of the field, &c. off-ſets are taken, i. e. the diſtance of the fence from the ſtationary line is meaſured at each ſtation; and even at intermediate places, if there prove any conſiderable bends in the fence.

In *plotting*, therefore, the ſtationary lines being laid down, as above, the off-ſets muſt be laid down from them; i. e. perpendiculars of the proper lengths muſt be let fall at the proper places from the ſtationary lines. The extremes of which perpendiculars, being connected by lines, give the *plot* deſired.

If, inſtead of going round the field, the angles and diſtances have been all taken from one ſtation, the proceſs of *plotting* is obvious, from the example above; all here required, being to protract, after the manner already deſcribed, the ſeveral angles and diſtances, taken from the ſame ſtationary point in the field; from the ſame point or centre on the paper. The extremities of the lines thus determined, being then connected by lines, will give the *plot* required.

If the field has been ſurveyed from two ſtations, the ſtationary lines are to be firſt *plotted*, as above; then the angles and diſtances taken from each, to be laid down from each reſpectively.

PLOTTING, *the method of, where the angles are taken by the theodolite*, i. e. *by back-ſight and fore-ſight line* (it is called) is ſomewhat different. To prepare the angles for *plotting*, the quantity of each muſt firſt be found, by ſubtracting the degrees of the fore-ſight and back-ſight from each other: the remainder is then the angle to be protracted. The uſe of parallel lines is here excluded; and inſtead of laying the protractor conſtantly on, or parallel to meridians, its direction is varied at every angle. The practice is thus:

Suppoſe the former incloſure to have been ſurveyed with the theodolite, after the manner of back-ſight and fore-ſight; and ſuppoſe the quantity of each angle to be found by ſubtraction.

An indefinite line is drawn at random, as A K, *fig.* 43; and on this the meaſured diſtance, e. gr. 8 chains, 72 links, is ſet off, as in the former example: if now the quantity of the angle A have been found 140°, the diameter of the protractor is to be laid on the line A K, with the centre over A; and againſt the number of degrees, viz. 140, a mark made, an indeterminate line drawn through it, and the diſtances of the line A B laid down from the ſcale thereupon.

Thus we gain the point B; upon which laying the centre of the protractor, the diameter along the line A B, the angle B is protracted, by making a mark againſt its number of degrees, drawing an occult line, and ſetting off the diſtance B C, as before.

Then proceed to C, laying the diameter of the protractor on B C, the centre on C protracts the angle C, and draw the line C D: thus, proceeding orderly to all the angles and ſides, you will have the *plot* of the whole incloſure A B C, &c. as before.

PLOTTING *ſcale*, a mathematical inſtrument uſually of box wood, ſometimes of braſs, ivory, or ſilver, and either a foot, or half a foot long, and about an inch and a half broad.

It is denominated from its uſe in PLOTTING of grounds, &c.

On one ſide of the inſtrument (repreſented *Tab.* II. *Survey. fig.* 44.) are ſeven ſeveral ſcales, or lines, divided into equal parts. The firſt diviſion of the firſt ſcale is ſubdivided into ten equal parts, to which is prefixed the number 10, ſignifying that ten of thoſe ſubdiviſions make an inch; or that the diviſions of that ſcale are decimals of inches.

The firſt diviſion of the ſecond ſcale is likewiſe ſubdivided into 10, to which is prefixed the number 16, denoting that ſixteen of thoſe ſubdiviſions make an inch. The firſt diviſion of the third ſcale is ſubdivided in like manner into 10, to which is prefixed the number 20. To that of the fourth ſcale is prefixed the number 24; to that of the fifth, 32; that of the ſixth, 40; and that of the ſeventh, 48; denoting the number of ſubdiviſions equal to an inch, in each, reſpectively.

The two laſt ſcales are broken off before the end, to give room for two lines of chords, marked by the letters C C.

On the back-ſide of the inſtrument is a diagonal ſcale, the firſt of whoſe diviſions, which is an inch long, if the ſcale be a foot, and half an inch, if half a foot, is ſubdivided, diagonally, into 100 equal parts; and at the other end of the ſcale is another diagonal ſubdiviſion, of half the length of the former, into the ſame number of parts; viz. 100.

Next the ſcales, is a line divided into hundredth parts of a foot, numbered 10, 20, 30, &c. and a line of inches ſubdivided into tenths, marked 1, 2, 3, *&c.*

PLOTTING *ſcale, uſe of the.* 1. *Any diſtances being meaſured with the chain, to lay it down on the paper.* Suppoſe the diſtance to be 6 chains, 50 links. Draw an indefinite line; ſet one foot of the compaſſes at figure 6 on the ſcale, e. gr. the ſcale of 20 in an inch, and extend the other to five of the ſubdiviſions, for the 50 links: this diſtance, being tranſferred to the line, will exhibit the 6 chains 50 links, required.

If it be deſired to have 6 chains 50 links, take up more or leſs ſpace, take them off from a greater or leſſer ſcale, i. e. from a ſcale that has more or fewer diviſions in an inch.

To find the chains and links contained in a right line, as that juſt drawn, according to any ſcale, e. gr. that of 20 in an inch. Take the length of the line in the compaſſes, and, applying it to the given ſcale, you will find it extend from the number 6 of the great diviſions to five of the ſmall ones; hence the given line contains 6 chains 50 links.

PLOTTING-*table*, in *Surveying*, is uſed for a plain *table*, as improved by Mr. Leighton, who has obviated a good many inconveniencies attending the uſe of the common plain *table*. See Phil. Tranſ. N° 361. ſect. 1.

PLOTUS, in *Ornithology*, a genus of the *anſeres*, in the Linnæan ſyſtem: its characters are, that the beak is ſtreit, ſharp, and denticulated; the face covered, and the feet palmated, with the toes joined. Of this genus there is only one ſpecies, which is the ANHINGA of Marcgrave.

PLOVER, *golden*, or *green*, *pluvialis*, in *Ornithology*, the CHARADRIUS *pluvialis* of Linnæus; an elegant ſpecies, which is often found on our moors and heaths, in the winter time, in ſmall flocks. Its weight is nine ounces, its length eleven inches and breadth twenty-four; the bill is ſhort and black; the feathers on the head, back, and coverts of the wings, are black, beautifully ſpotted on each ſide with light yellowiſh green; the breaſt brown, marked with greeniſh oblong ſtrokes; the belly white, the middle feathers of the tail barred with black and yellowiſh green, the reſt with black and brown, and the legs black. Mr. Pennant has obſerved ſome variety in theſe birds, probably owing to age or ſex; ſome having black bellies, others with a mixture of black and white, others with bluiſh legs, and ſome with a ſmall claw in the place of the hind toe. This bird, which lays four eggs, pointed at the leſſer end and of a dirty white colour, irregularly marked with black ſpots, breeds on ſeveral of our unfrequented mountains: it makes a ſhrill whiſtling noiſe, and may be enticed within ſhot by a ſkilful imitator of the note. Pennant.

PLOVER, *horned*. See LAPWING.

PLOVER, *leſſer*, CHARADRIUS *minutillus* of Linnæus. See DOTTEREL.

PLOVER, *long-legged*. See HIMANTOPUS.

PLOVER, *Norfolk*, or *greater*. See OEDICNEMUS, and *Stone* CURLEW.

PLOVER, *ringed*. See *Sea*-LARK, and *Tab. Birds*, N° 45.

PLOVER-*ſtone*, in *Lithology*, a name uſed in ſome parts of England for the GODWIT, or *ægocephalus* of authors.

PLOUGH, or PLOW, in *Agriculture*, a popular machine for the breaking up of ground; conſiſting of a train or carriage with two large irons, the one pointed, the other edged; ſerving to cut and open the land, and draw furrows therein. The parts of the PLOUGH are, the *plough-beam*, the *handle*, *tail*, *ſtilts*, *holes* or *mortiſes*, *neck* or *ſhare-beam*, *earth-board*, *mould-board*, *breaſt-board*, *furrow-board*, *ſtretch-board*, &c. the *ſheath*, *ſhare-iron*, *coulter*, *plough-pin*, and *cellar-links*, *plough pillar*, and *boſſers*, and ſometimes *wheels*.

The advantage of digging with the ſpade, or ſuch other inſtrument, very naturally led men to the invention of the *plough*, as a much more expeditious way of doing the ſame thing; that is, cutting and breaking the earth into ſmall pieces; but in this the ſpade has the advantage of the common *plough*, as it goes deeper, and divides the earth more minutely; but the improvement of the common *plough* into the four-coultered one ſhews, that it is eaſy to make the *plough* perform this office as much better, as it uſually does it worſe than the ſpade.

The *plough* deſcribed by Virgil had no coulter; and at this time the *plough* in Italy and the ſouth of France, have none; and the *plough* in Greece, and in the eaſtern nations in general, are of the ſame kind. Neither is it indeed poſſible to uſe a coulter in ſuch a *plough*; becauſe the ſhare does not cut the bottom of the furrow horizontally, but obliquely: in going one way it turns off the furrow to the right hand, but in coming back it turns it off to the left; therefore, if it had a coulter, it muſt be on the wrong ſide every other furrow.

It is a great miſtake in thoſe who ſay that Virgil's *plough* had two earth-boards, for it had really none at all; but the ſhare itſelf always going obliquely, ſerved inſtead of an earth-board; and the two ears, which were the corners of a piece of wood lying under the ſhare, did the office of ground-wreſts.

This faſhion of the *plough* continues to this day in thoſe countries; and in Languedoc this ſort of *plough* performs tolerably well when the ground is fine, and makes a ſhift to break up light land. This is the ſort of land that is common in the Eaſt; and the arable lands about Rome being never ſuffered to be fallow ſo long as to come to turf: this *plough* ſucceeds very well in ſuch places, but it would be wholly impoſſible to turn up what in England we call ſtrong land with it.

The Engliſh *plough* is therefore different from theſe, as the ſoil is different. Our *plough*, where well made, cut off the furrow at the bottom horizontally; and therefore, it being as thick on the land ſide as on the furrow ſide, the *plough* cannot break it off from the whole land at ſuch a thickneſs (being ſix times greater than what the eaſtern *plough* have to break off), and for this purpoſe it muſt have, of neceſſity, a coulter to cut it off: by this means the furrow is turned perfectly whole, and no part of the turf of it is broken; and if it lie long without new turning, the graſs from the edges will ſpread, and form a new turf on the other ſide, which was the bottom of the furrow before the turning, but is now become the ſurface of the earth, and will ſoon become greener with graſs than it was before *ploughing*.

If the ſoil be ſhallow, it may be broken up with a narrow furrow, which will the ſooner be brought into tilth; but if it be a deep ſoil, the furrows muſt be proportionably enlarged, or elſe a great part of the good mould will be left unmoved, and ſo be loſt. The deeper the land is, the worſe it is broke by one coulter; that is, it is broke into larger furrows, and it requires ſuch repeated labour to conquer this, that often the beſt land will ſcarce pay the tillage.

This gives an opportunity to ſervants to cheat their maſters. They *plough* ſuch deep land with a ſmall furrow, and ſhallow, to the end that the turf and furrows may be broken the ſooner, and the ſuperficial part made fine. They pretend the *plough* will go deeper the next time; but this is never the caſe.

This ſort of land muſt not be *ploughed* the ſecond time in wet weather; for this will cauſe the weeds to multiply, and the earth will be formed into thick and heavy clods where trodden: and in dry weather the reſiſtance of the untouched earth below, and the ſlight preſſure of the *plough* above, will always be reaſons why the *plough* will enter no deeper the ſecond time than it did the firſt.

Another way to conquer a ſtrong turf, is to plough it up firſt with a breaſt-*plough*, very thin; and when the ſward is rotten, then it is to be *ploughed* to the proper depth: but this method is liable to great objections; it is very troubleſome and expenſive, and, if the turf be pared off in the winter, or early in the ſpring, it is a chance but the rains come on, and ſet it to growing faſter than before: if, on the other hand, it be pared later in the year, though the turf be thoroughly killed by the ſucceeding dry weather, yet the time is loſt, and the farmer loſes the ſowing ſeaſon for wheat, which is the proper corn for ſuch ſtrong land. Tull.

The contrivance and ſtructure of *ploughs* are various, according to the fancy of the maker, or the ſoil and uſes to which they are applied; ſo that it would be endleſs to give a particular deſcription of all: but that this work may not be thought eſſentially defective in this particular, we ſhall here ſubjoin a brief account of ſeveral kinds of *ploughs* that have fallen under our notice, and that have been recommended by the advantages attending their ſtructure.

The common *dray* or *draw* PLOUGH is well known: this is made without either wheel or foot, of an eaſy draught, and beſt in winter for miry clays, where the land is ſoft: but in ſummer and eſpecially in hard ſoil it is inconvenient, becauſe its point will be continually riſing out of the ground.

In the *double* PLOUGH, one *plough* is fixed to the ſide of another, ſo that by means of four horſes and two men, a double furrow is *ploughed* one by the ſide of the other.

There is another kind of *double plough* whereby two furrows are *ploughed* at once, one under another, by which the earth is ſtirred up to the depth of twelve or fourteen inches, which in many caſes is of great benefit.

This purpoſe is well anſwered by the *double* PLOUGH invented by Mr. Randal, (ſee *Tab. Agriculture, fig.* 7.) which, by parting the ſhare point to the middle of the interval left by the horſe-hoe, throws the mould off each ſide of it, at the ſame time, towards the rows, and earths them up to what degree the ploughman pleaſes: and alſo by the *double lifting* PLOUGH, (*fig.* 8.) which paſſes into all the trenches made by the *double plough*, and by means of the irons, running up on each ſide of the *plough*, will lift up the mould, and throw it upon the old ridges; ſo that the ground, thus *ploughed*, will lie in deep trenches and high ridges.

The *double wheeled* PLOUGH has of late years become univerſally uſed in many counties, and is found much preferable to the *ploughs* they uſed before; there is an objection

objection to it indeed, in regard to some stiff and miry lands, in which the wheels become clogged up, and cannot turn. This, however, is easily remedied by twisting thumb ropes of straw about the iron circle and spokes of the wheels; these spreading as they turn, and as the circle twist bears upon the ground, throw off the dirt, and never clog. The two principal parts of this *plough* are the head and the tail: the *plough*-head contains the two wheels A, B (*fig. 6.*) and their axis, or spindle of iron, passing through the box C, and turning round both in it and in the wheels. There are fixed perpendicularly in this box, two crow-staves D, D, which are flat and narrow boards, each having in it two rows of holes, whereby to raise or sink the beam of the *plough*, by pinning up or down the pillow E, to increase or diminish the depth of the furrow. Behind are the gallows F, through which the crow-staves pass at the top by mortises, into which they are pinned; and to these are fastened what are called the wilds, G, with links and crooks of iron, by which the whole *plough* is drawn in the working. From the box to the centre of the beam there is carried an iron-chain, consisting of four, five, or more long links, and called the tow-chain, H: this fastens the *plough*-tail to the *plough*-head. It is fixed to an iron collar, I, fastened in the beam at one end, and the other passes through a hole in the middle of the box, and is pinned in by the flake K. From the same iron-collar to which the tow-chain is fixed, there is another chain fastened, called the bridle-chain L: this runs above the beam, as the tow-chain does below it, and is composed of smaller and more numerous links. At the up-end, as the tow-chain enters the box of the *plough*, this bridle-chain is fixed to the top of what is called the flake of the *plough*; this is a perpendicular stick, carried up parallel with the left crow-staff, and pretty near it, and fastened to it by a wyth or rope, M, or by the end of the bridle-chain itself, when that is long enough. This flake is also fastened in its lower part, under the gallows, to the same crow-staff, by another wyth or piece of rope.

These are the parts of which the head-part of the *plough* is composed. The *plough*-tail consists of the beam, N, carried from the head to the very extremity, and serving as the support and base of all the rest. A little below the collar, to which the tow-chain and bridle-chain are fastened, this beam is pierced with a large hole, which lets through the coulter, O: this is a long and narrow piece, terminating in an edge, and reaching just to the share, P; and it is fixed immoveable in its place by means of a wedge which is driven into the hole of the beam with it: the office of this coulter is to cut the earth as it is thrown up by the share. Behind these, the same beam is pierced with two more holes, one very near its end: these give passages to two oblong pieces, called the fore-sheat Q and hinder-sheat R, by which the *plough*-share is supported in its place. To the top of the hinder-sheat there is fastened a short handle, S, by a wooden pin. Parallel to the hinder-sheat there runs up a piece of wood of much the same form, called the drock, T; and to this is fastened another horizontal piece, called the ground-swill, V: these are all on the right hand side of the *plough*, and parallel with the fore-sheat. There runs another piece, of much the same form with it, on the right hand; and the bottom of this is the earth-board, whose fore-part, W is seen before the sheat. The long handle, X, of this whose fore-part appears before the sheat, which reaches as far as that of the sheat, is fastened to the drock by a pin at *a*, the other end of which goes into the beam. Near the lower end of the fore-sheat, there are two flat pieces of iron, called the double retch, *z*, which pass from the two sides of it up to the beam; and, being let through it, are fastened to the upper part by screws and nuts at *b* and *c*. These keep the sheat in its place.

PLOUGH, *draining*, or *trenching*, is an instrument used to cut out the trenches, drains, and carriages in meadow and pasture-ground. It is also used for cutting the sides of turf even, which are to be laid down again either in the same, or in some other places.

It consists of a long handle, with a knob or button at the end, and at the other end it turns upward like the foot of a *plough*, to slide in the ground. In this part is placed a coulter, of the length proportioned to the depth to be cut, and with a sharp edge; this has two wheels to make it run easy, and does a great deal of business in a very little time.

The *trenching-plough* used about Caxton, in Cambridgeshire, is larger than ordinary, and has two coulters, one before the other, which, bending inwards, cut each side of the trench. The mould-board is longer than common, in order to cast the turf a great way off from the trench. It cuts a trench a foot wide at bottom, a foot and a half at top, and a foot deep, and is drawn with twenty horses. The importance of draining wet land induced the Society of Arts, &c. to propose a premium of fifty guineas for the best *plough* or machine, of the simplest construction, that should, with the least force, cut a new drain or trench one foot in perpendicular depth, one foot eight inches wide at top, and ten inches at the bottom, sloping equally on each side, the contents of which were also to be thrown equally on each side.

This premium was adjudged to Mr. Cuthbert Clarke, who invented the *double* mould-board *drain-plough*, represented *Tab.* II. *Agriculture, fig.* 10. which answered exceeding well in meadow ground, but could not be drawn in a stiff clay with the force of eight horses.

A, B, and C are the three coulters; D, E, F, the nuts and screws that fasten the coulters to the beams; G, H, I a wheel or roller, which prevents the *plough* from sinking too deep into the earth; this roller is divided into three parts by circular pieces of iron, which project beyond it, and cut the turf into three parts; the coulters follow in the same track, and finish that part of the work. K, K, are the centres on which the roller turns; L, L, the nuts and screws which fasten the iron arbor in which the pivots of the roller turn to the beams; the arbors are kept in their places by means of the two iron braces *f*, *f*. M is a large iron hook, to which the tow-chain, N, by which the *plough* is drawn, is fastened: O is the head of the *plough*, into which the beams are mortised; P, Q, R are the three beams; S is a shoe of iron, the whole part from S to A being of that metal, and into which the hoof of the *plough* is inserted; T is a shelf on which the mould rises after it is cut by the coulter and fore-part of the share, till it is thrown out of the trench by the mould-boards V, V; W, W is a band of iron, which fastens the hinder part of the *plough* to the main or middle beam; X is the head of a tenon, which fastens the mould-boards and hoof of the *plough* to the main-beam; Z, Z are the two handles, like those of a common *plough*, kept secure, and in their proper position by the board *a b*; *c*, *d*, represent the surface of the ground when the *plough* is at work; so that all the parts below that dotted line are under the ground when the drain is cutting: *f e g* is the angle which the coulters make with a line drawn parallel to the horizontal plane, and is nearly equal to 45°: though by being so large, the *plough* tends too much to get into the earth; and, therefore, when the soil is stiff and a great force is required to draw the *plough*, it cannot be properly held by the handles, even by the force of six men, without turning over. This inconvenience might be removed by diminishing the angle *f e g* to about 33°. Mr. Clarke constructed another improved *plough* of this kind, but the premium of the society was assigned to Mr. Knowles, whose *plough* cut a trench of one foot one inch in depth, twenty inches broad at top, and ten at bottom, laying the earth and turf on each side of the trench in the most exact manner.

Mr. Clarke's *single mould-board drain-plough* is represented *fig.* 11. Its construction is very similar to that already described: A is the regulating wheel, which, by the radius F, may be so adjusted as to adapt the *plough* for cuts of various depths. H, H are two coulters fastened to the wings of the share, and screwed into the bar G; they are so extended as to make the designed breadth at top, and equally sloping on each side. In whatever way the cut is made, the contents are forced up the inclined plane C, which is supported by the heel D, as in the other *plough*; and the mould-board B turns the furrow clear of the drain. This *plough* requires only four horses. Clarke's Theory and Practice of Husbandry, &c. p. 332, &c.

PLOUGH, *drill*, is an instrument contrived for sowing corn in drills or rows, according to the method of the new husbandry.

The first inventions of this kind were the *drill-plough* of Mr. Worlidge, and the sembrador of Lucatello; but neither of these or any other of the kind answered in practice, till Mr. Tull contrived his *drill-plough*; furnished with shares, hoppers, and a harrow, so disposed, that the furrows are formed, the seed dropped into them, and covered at the same time. This curious machine is, from its nature and extensive use, so complicated, that it would lead us beyond our proper limits to give such a minute description of it, as would be sufficient to afford our readers an adequate and just idea of it. Such a description illustrated by various figures, together with the inventor's latest improvements, may be found in his Horse-hoeing Husbandry, chap. 21, 22, and Appendix. See DRILL.

Mr. Clarke, whose name has been already mentioned, has invented a *drill-plough*, (see *fig.* 12.) I I are a pair of shafts; J, L is a bar, which strengthens the hinges of the shafts; E, E, E are three mortises to receive the three coulters; A represents the shape of the coulter, the bulb at the end of which makes the groove or furrow for the seeds; B, B, B are oval holes to receive the piece

N, which conveys the seeds down to the furrows made by the coulters; *a*, *a*, *a*, are three flues or damsels, like those of a corn mill, to receive the seeds from the three hoppers R, R, R, which are placed about eight or nine inches above the board, containing the holes B, B, B, but parallel to it, and supported by the frame C, which frame is supported by seven pillars, such as *q*. The hoppers and their flues being thus suspended, and the flues pinned to a flat bar as represented by B, B, B, and held to their station by an easy spring, they are jogged by the call or square piece of wood fixed upon the spindle, passing through the trundle O: this trundle is turned by the cog wheel H, which is turned by the axle-tree *Z Z* of the two wheels G G: *g* is the bridge for supporting the spindle and trundle. When the seed, jogged by the call, is made to trickle out, a person takes hold of the handles P P, and directs the whole machine, so that the seeds will be covered in by the harles *d*, *d*, *d*; which turn upon a pin or hinge at the fore end, and are loaded at the hind end with lead or any other heavy substance, as represented by the balls over *d*, *d*, *d*, to make the feet sink in the soil. This instrument may be made to shift its drills at pleasure, or to drill always at one distance. Clarke ubi supra.

For the method of constructing *drill-ploughs*, invented by M. de Chateauvieux and Du Hamel, see Farmer's Dict. art. DRILL-*plough*.

Mr. Randall, Mr. Craik, and Mr. T. Hope, have likewise constructed *drill-ploughs*.

The *four-coulered* PLOUGH of Mr. Tull, (*see fig.* 13) is different in some respects from the *double-wheeled plough* already described, though in general founded upon it.

Its beam is ten feet four inches long, whereas that of the common *plough* is but eight. The beam is straight in the common *plough*, but in this it is straight only from *a* to *b*, and thence arched: so that the line let down perpendicularly from the corner at *a*, to the even furface on which the *plough* ſtands, would be 11½ inches; and if another line were let down from the turning of the beam at *b* to the ſame furface, it would be one foot eight inches and a half: and a third line let down to the furface from the bottom of the beam at that part which bears upon the pillow, will ſhew the beam to be two feet ten inches high in that part. At the diſtance of three feet two inches from the end of the beam *a*, at the *plough*-tail, the firſt coulter, or that next the ſhare, is let through; and at thirteen inches from this, a ſecond coulter is let through: a third at the ſame diſtance from that; and, finally, the fourth at the ſame diſtance from the third, that is, thirteen inches: and from *a* to *b* is ſeven feet.

The crookedneſs of the upper part of the beam of this *plough* is contrived to avoid the too great length of the three foremoſt coulters, which would be too much, if the beam was ſtraight all the way; and they would be apt to bend and be diſplaced, unleſs they were very heavy and clumſy. Aſh is the beſt wood to make the beam of, it being ſufficiently ſtrong, and yet light.

The ſheat in this *plough* is to be ſeven inches broad. The fixing of the ſhare in this, as well as in the common *plough*, is the niceſt part, and requires the utmoſt art of the maker; for the well-going of the *plough* wholly depends upon the placing this. Suppoſing the axis of the beam, and the left ſide of the ſhare, to be both horizontal, they muſt never be ſet parallel to each other; for if they are, the tail of the ſhare bearing againſt the trench as much as the point, would cauſe the point to incline to the right hand, and it would be carried out of the ground into the furrow. If the point of the ſhare ſhould be ſet ſo, that its ſide ſhould make an angle on the right ſide of the axis of the beam, this inconvenience would be much greater; and if its point ſhould incline much to the left, and make too large an angle on that ſide with the axis of the beam, the *plough* would run quite to the left hand; and if the holder, to prevent its running quite out of the ground, turns the upper part of his *plough* towards the left hand, the pin of the ſhare will riſe up, and cut the furrow diagonally, leaving it half *unfurrowed*. To avoid this and ſeveral other inconveniencies, the ſtraight ſide of the ſhare muſt make an angle upon the left ſide of the beam; but that muſt be ſo very acute a one, that the tail of the ſhare may only preſs leſs againſt the ſide of the trench than the point does.

This angle is ſhewn by the pricked lines at the bottom of *fig.* 9, where *e f* is ſuppoſed to be the axis of the beam let down to the ſurface, and *g f* parallel to the left ſide of the ſhare: and it is the ſubtenſe *e g* that determines the inclination which the point of the ſhare muſt have towards the left hand. This ſubtenſe, ſays Mr. Tull, at the fore-end of an eight feet beam, ſhould never be more than one inch and a half, and whether the beam be long or ſhort, the ſubtenſe muſt be the ſame.

The great thing to be taken care of, is the placing the four coulters; which muſt be ſo ſet, that the four imaginary places deſcribed by their four edges, as the *plough* moves forward, may be all parallel to each other, or very nearly ſo; for if any one of them ſhould be very much inclined to, or ſhould recede much from either of the other, then they would not enter the ground together. In order to place them thus, the beam muſt be carefully pierced in a proper manner. The ſecond coulter-hole muſt be two inches and a half more on the right hand than the firſt, the third muſt be as much more to the right of the ſecond, and the fourth the ſame meaſure to the right hand of the third; and this two inches and a half muſt be carefully meaſured from the centre of one hole to the centre of the other. Each of theſe holes is a mortiſe of an inch and quarter wide, and is three inches and a half long at the top, and three inches at the bottom. The two oppoſite ſides of this hole are parallel to the top and bottom, but the back is oblique, and determine the obliquity of the ſtanding of the coulter, which is wedged tight up to the poſt.

The COULTER is two feet eight inches long, before it is worn; the handle takes up ſixteen inches of this length, and is allowed thus long, that the coulter may be driven down as a point wears away.

As to the wheels, the left hand wheel is twenty inches diameter, and that on the right hand two feet three inches, and the diſtance at which they are ſet from each other is two feet 5½ inches. Tull's Horſe-hoeing Huſband. p. 294, ſeq.

PLOUGH, *hoe*, an inſtrument adapted to the new HUSBANDRY, and to the operation of HOEING, for deſtroying weeds, keeping plants clean, and ſtirring the ground. See *Horſe*-HOE.

The *bar-plough* invented by Mr. Tull, is repreſented in *fig.* 14. A is the beam and *plough*-tail; being much the ſame with that of the common *plough*, *fig.* 9. The ſhare from its tail to the fore-part of its ſocket is two feet one inch long, and from thence to the end of the point ten ½ inches. B is the plank, two feet ſeven ½ inches long, two ½ inches thick, and nine inches broad. C, D are the nuts of the two ſcrew-pins, which hold up the beam to the plank: E is the nut of the draw-pin, which pin has a crook underneath, to which one of the links of the ſhort chain of the whipper is faſtened, for drawing the *plough*: F, G are the two limbers, ſcrewed on to the plank by four ſcrews and nuts, and having their inferior ſurface parallel to the plank, and to the upper ſurface of the fore-end of the beam: theſe limbers bend outwards from each other all the way, till they come within about a foot of the chain; and the diſtance of their fore-ends is two feet eight inches: they are to be made ſtrong and ſtiff, and of ſuch a length, that there may be room for the horſe before the bar, H, which holds them at their proper diſtance: I is the whipper: K, L are its *neſtches*, to which the traces, both of the thiller and of the horſe next before him, are faſtened.

This *plough* is made to go deeper or ſhallower by the chain of the limbers. In hoeing near the young plants, the firſt or ſecond time, the earth is prevented from running over to the left ſide of the *plough*, and burying them, by nailing a very thin ſquare piece of board to the ſheat with one corner bearing at or below *a*, and its other lower corner bearing on the back of the coulter on its left ſide at *b*, its upper corner reaching to *c* or higher: its fore end is tied on to the coulter by a leathern thong paſſing through a hole very near the end of the board. The lower edge of the board muſt come no lower than the pricked line *a b*; which at *b*, is juſt even with the ſurface of the ground, before it is raiſed by the ſhare. For a farther account of the ſtructure and uſe of this *plough*, ſee Tull, ubi ſupra, chap. 23.

PLOUGH, *paring*, is an inſtrument uſed in ſeveral parts of England, for paring off the ſurface of the ground, in order to its being burnt.

Mr. Bradley has given the following deſcription of a very ſimple inſtrument of this kind: from A to A (*fig.* 15.) is the *plough*-beam, about ſeven feet long, mortiſed and pinioned into the block B, which is of clean timber without knots. C, C are the theaths or ſtandards, made flat on the inſide, to clole equally with the paring plate, and faſtened to it with a bolt and key on each ſide, as at D. E is the paring plate of iron laid with ſteel, about four inches wide, and from twelve to eighteen inches long. This plate muſt be made to cut on the ſides, which are bolted to the ſtandards, as well as at the bottom part. F, F are two iron braces, to keep the ſtandards from giving way: theſe ſtandards muſt be mortiſed near their outſides, and through the block. G, G are the *plough* handles, which muſt be fixed ſlope-ways between the beam and the ſtandards. The pin-holes in the beam, the uſe of which is to make this *plough* cut more or leſs deep, by fixing the wheels nearer to or farther from

the paring plate, ſhould not be above two inches aſunder.

PLOUGH, *Rotheram*, or *paring*, is a *plough* of very ſimple conſtruction, and eaſily worked. The left or land ſide of this *plough* is repreſented *fig.* 16. A B is the beam, C D the ſhank, E F D the main handle, F R the ſmaller handle, G H the coulter, K I the ſock or ſhare, N P the bridle, O the fly-hand, and M L a piece of wood in place of a head. The whole of this *plough* ſhould be made of aſh or elm; the irons ſhould be ſteeled and well-tempered; and that part of the *plough* which is under ground in rolling, ſhould be covered with plates of iron. The difference between this and the common *plough* ſeems to conſiſt in the bridle at the end of the beam, by which the *ploughman* can give the *plough* more or leſs land by notches at N, or make it cut deeper or ſhallower by the holes at P; in the coulter or ſhare, which are to made and ſet as to cut off the new furrow without tearing; and in the mould-board, which is ſo ſhaped at firſt to raiſe a little, and then gradually turn over the new cut furrow with very little reſiſtance. But the greateſt advantage attending it in its being ſo eaſy of draught, that it will do double the work of any common *plough*. Mr. Clarke has alſo conſtructed a *plough*, which he ſays, may be worked with the leaſt force poſſible. Clarke, *ubi ſupra*, p. 347.

For an account of the improvements made in wheeled *ploughs* by Meſſrs. de Chateauvieux and Du Hamel, we muſt refer the reader to the Farmer's Dictionary, art. PLOUGH.

PLOUGH, *the ſingle-wheel*, is lighter than moſt other wheel-*ploughs*, and may be uſed almoſt in any kind of ground; though in Suſſex they have a *plough* of this kind, wide in the breech, and of heavy draught.

PLOUGH, *Spaniſh*, varies much in its make from our common *plows*. It is a kind of ſamicircle pitched on one end, with the convex ſide turned to the ploughman; and the concave ſide (a little inclined) to the horſe. Its tail is in a right line with the ſhare. With this *plough* and one horſe the Spaniards *plow* two or three acres of their light ground in a day. See *fig.* 17.

PLOUGH, among *Book-binders*, is a tool wherewith they cut the leaves of books ſmooth. See BOOK-BINDING.

PLOUGH, or *plow*, in *Navigation*, an ancient mathematical inſtrument made of box or pear-tree, and uſed to take the height of the ſun, or ſtars, in order to find the latitude.

It admits of the degrees to be very large, and has been much eſteemed by many artiſts; though now generally diſuſed amongſt us.

PLOUGH-*bote*, in our *Old Writers*, a right of tenants to take wood to repair *plough*s, carts, and harrows, and for making rakes, forks, &c.

PLOUGH, *gallows of a*. See GALLOWS.

PLOUGH-*land*, a name given by the farmers to the foremoſt half of the *plough*, or that part containing the two wheels and their ſpindle, the box, the crow-ſtaves, the pillow, the wilds, the tow-chain, and bridle-chain, and the ſhake; all which, ſee under their ſeveral heads, and under the article PLOUGH.

PLOUGH-*land*, *carucata terræ*, in our *Ancient Cuſtoms*. See CARUCATE.

PLOUGH-ALMS, a duty anciently of a penny, paid to the church for every *plough-land*, or hide of land.

Dequalibet carucata juxta inter Paſcha & Pentecoſten unum denarium, qui dicitur plou-almes. Monaſt. Ang.

PLOUGH-MONDAY, the next Monday after Twelfth-day. The ploughmen, in the north-country, on this day, draw a *plough* from door to door, and beg *plough* money for drink.

PLOUGH, *handles of a*, the name given by Farmers, to the two pieces of the *plough* faſtened to the earth-board, and to the heeſt, and ſerving the ploughman to reſt his force upon in the guiding of the *plough*. When they are conſiderably long, the *plough* is always guided the better, and the land is better tilled; but the lazy ploughmen are apt to cut them off ſhorter, that by bearing their whole weight upon them, they may, in a manner, ride, inſtead of walking. If they ſhould ride, in this manner, on the long handles, they would tilt up the end of the beam, and raiſe the *plough* out of the ground.

PLOUGH-*irons*, a name given by the farmers to that part of a *plough* which contains the beam, the coulter, or coulters, the ſhare, the throat and under-throat, the earth-board and handles, as alſo the ſtork, the ground-wriſts, and the retches: all which ſee under their ſeveral heads, and under the article PLOUGH.

PLOUGHING, or PLOWING, one of the principal operations in agriculture, performed with the *plough*.

Ploughing is principally either that of *lays*, or of *fallows*.

PLOUGHING *of lays*, is the firſt cutting up of graſs-ground for corn; to which ſafe the Engliſh writers on agriculture always ſuppoſe, that the land is to be ſometimes followed; and they recommend to plough as deep at firſt as the nature of the ſoil will allow; directing alſo to turn the earth upſide down, that the ſward or turf may be ſooner rotten. On the rich lands in Scotland they purſue a method the reverſe of this: they commonly ſow after one *ploughing* of graſs-ground, and plough as ſhallow and narrow as poſſible, and let the turf as exactly as poſſible upon its edge. In this way it may be expected, that after ſeed, the turf will be in ſtaving in ſuch a condition as to be eaſily broken by the harrows, and fit for being ſown with corn, or to be ſummer fallowed, and ſown with wheat. With reſpect to their barren lands, they purſue the Engliſh method, *ploughing* deep and turning the turf over on its back. There is another method propoſed for opening up graſs-ground, and that is by trench-*ploughing*. This manner of *ploughing* is performed by one plough following another in the ſame track. The plough that goes firſt turns over the ſward or turf, and the ſecond turns up ſome inches of ſoil upon it. By this method there is ſufficient nouriſhment provided for the crop, and the ſward is rotten before the next ſeaſon.

PLOUGHING *of fallows*, called *after-following*, is a preparing of land by *ploughing*, long before it be *ploughed* for ſeed. This is a conſiderable benefit to all lands, few of which will bear above two or three crops ſucceſſively without ſuch reſpite. Hence lands uſe to hire their tenants to do it once in three years. When this is done twice, it is called *twi-following*; when thrice, *tri-following*, &c.

The firſt is as ſoon as the huſbandman has done ſowing his corn; and this is to be very ſhallow, well turned, and clapped cloſe together. The ſecond is in June, when they go to the full depth. The third, about the beginning of Auguſt. If it riſe full of clods, they harrow it down; but then they ſoon ſtrick-*fize*, or *plough* it up again into ridges.

In Staffordſhire, beſides the three ſummer fallowings, they uſually give their land a winter fallowing. Pliny commends the *ploughing* of lands four times; and ſo does Virgil:

Illa ſeges demum votis reſpondet avaris
Agricolæ, bis quæ ſolem, bis frigora paſſa —Georg. lib. i.

This is an ancient part of huſbandry; Xenophon, Pindar, and Virgil recommended it:

Alterno idem tempore, ceſſare novalis,
Et ſegnem patiere ſitu durescere campum. —Georg. lib. i.

The great end of *ploughing* is to break and pulverize the ſoil as much as poſſible, for the deſtruction of weeds, the more eaſy ſpreading of the roots of plants, and their better nouriſhment. This operation ſhould therefore be often repeated, and by ſuch ploughs as have two or four coulters; the furrow ſhould not be made too broad, and care ſhould be taken that it be made ſufficiently deep. See PLOUGH, and HUSBANDRY.

If between each *ploughing* of the land a harrow with long teeth is made uſe of to tear and break the clods, it will be of great ſervice; eſpecially if the land is ſtrong: for the more it is ſtirred by different inſtruments, the better will the parts be ſeparated and pulverized. The common method, as practiſed by the farmers when they fallow their land, is far from anſwering their intention, for they *plough* up the ground, leaving it in great clods for ſome months, and frequently during this time, thiſtles and all bad weeds are ſuffered to grow upon the land, and exhauſt the goodneſs of it; and perhaps juſt before the ſeeds are ſown, they give it two more *ploughings*. This is what the farmers call good huſbandry: but inſtead of this method they ſhould labour the ground often with the plough, a harrow, and heavy roller, to break and ſeparate the parts, and never ſuffer any weeds to grow upon the land during its lying fallow, they would find their account in it; firſt by the growth and increaſe of their crops, and afterward by a ſaving in the weeding; for if no weeds are ſuffered to grow to ſhed their ſeeds, during the time of fallowing the land, there will but few come up when the ground is ſown.

Ploughing in ridges is very proper for removing wetneſs, in which caſe every furrow becomes a drain, and alſo for enlarging the ſurface of the ſoil, expoſed to the air, and employed in vegetation. In order to obtain theſe purpoſes, the ridges ſhould be narrow; though ſoils in different ſituations will require being laid out in different kinds of ridges: they ought alſo to be ſtraight in their directions, and equal to one another in ſize, each ridge being alſo equally broad in all its parts. See RIDGES.

There are three different ways of *ploughing* ridges, viz. gathering, caſting, and cleaving.

Gathering keeps the crown and furrows of the ridge in the ſame place in which they were before. The plough begins in the crown, and ploughs out the ridge, turning

the earth towards the crown: by this method of *ploughing* the earth on each side is turned upon the crown, and thrown up out of the furrows, so that the ridge is raised. Casting likewise keeps the crowns and furrows in the same place; the ridges are ploughed in pairs, and they are kept of the same height in the crown, and one of the furrows made a little higher, and the other a little lower than before; the earth being taken out of one furrow and thrown into the other.

Cleaving is the reverse of gathering: the plough enters the furrow on the right side of the ridge, turns to the furrow on the left side, and ploughs out the ridge, turning the earth from the crown towards the furrow. In this case the furrows are made higher and the crown lower.

There is another method of *ploughing* called *ribbing*, which is performed by making furrows about two feet distant from each other; one half of the surface is untouched by the plough, and the other half, which the plough turns up in making the furrows, is thrown on the top of what remains fast. This kind of *ploughing* is seldom practised, but in the beginning of winter, and upon land to be sown with barley, after two more clean *ploughings*. It is much condemned by the modern improvers of agriculture, though in some cases it has its use.

Boaring is another kind of *ploughing*, performed by throwing the earth of two furrows towards each other upon some fast land; this is an improvement of ribbing, and better serves the same purposes.

PLOUGHMAN, in *Husbandry*, the person who guides the PLOUGH, in the operation of tilling or TILLAGE.

PLOUGHMAN'S *spikenard*, the English name of a genus of plants called by the botanists *conyza*; it is likewise called by us FLEA-*bane*.

PLUG, a large wooden peg, wherewith to stop the bottom of a cistern, cask, pipe, or the like.

PLUGS, in *Shipping*, are certain pieces of timber, formed like the frustum of a cone, and used to stop the hause-holes, and the breaches made in the body of a ship by cannon-balls; the former of which are called *hause-plugs*, and the latter *shot-plugs*, which are formed of various sizes, in proportion to the holes made by the different size of shot which may penetrate the ship's sides or bottom in battle: accordingly they are always ready for this purpose.

PLUKENETIA, in *Botany*, the name of a genus of plants described by Plumier, and called by this name in honour of Plukenet, the great English botanist. In the Linnæan system it belongs to the class of *monœcia adelphia*.

The characters are these: it produces male and female flowers on the same plants; the male flowers have no cup, but are composed of four expanded petals of an oval figure, eight stamina, and four bearded nectaria; the female flowers have no cup, and the four petals in these are disposed as in the male; the germen of the pistillum is square; the style is slender, very long, and crooked; the stigma is peltated and divided into four parts; the segments are obtuse and flat, and each has a remarkable spot in the centre; the fruit is a depressed square capsule, hollowed at all the angles; it contains four bivalve cells; the seeds are single, roundish, and compressed, and bluntly pointed at one end.

Linnæus observes, that this fructification is very singular; and is very desirous, that some person should examine carefully the growing plant, since Plumier, who was not over curious about the nicer parts of the fructification of plants, may have in some sort misrepresented this. There is only one species.

PLUM-*tree*, *prunus*, in *Botany*, a genus of the *icosandria monogynia* class. Its characters are these: the flower hath a bell-shaped empalement, cut into five points; it hath five large roundish petals, which are inserted in the empalement, and from twenty to thirty stamina, which are near as long as the petals, and are also inserted in the empalement, terminated by twin summits; it has a roundish germen, supporting a slender style, crowned by an orbicular stigma; the germen afterwards turns to a roundish fruit, inclosing a nut of the same form. Miller reckons thirty-three, and Linnæus fourteen species.

All the sorts of *plums* are propagated by budding or grafting them upon the stocks of the muscle-*plum*, the white pear-*plum*, the St. Julian, or the bonum magnum. See INOCULATION.

Budding is much more proper than grafting for these trees, as they are apt to throw out a great deal of gum from the wound: and the trees should be no more than one year's growth from the bud, when they are transplanted; for if they are more they seldom succeed well, being very subject to canker; and if they escape that, they usually produce only two or three luxuriant branches. The whole management of planting and pruning them is the same with that of peaches. See PEACH.

If the walls against which they are planted are low, they should be set thirty feet asunder; if they are higher, then not less than twenty-four feet.

Plums should have a subsiding soil, for they seldom succeed well either in a too moist or too dry one; and, when planted against walls, should have an east or a south-east aspect. If they have one at full south, they are apt to shrivel up, and grow mealy.

Plums in general succeed very well with proper care on espaliers; they will also bear very well as standards, but the fruit will not be so well tasted. *Plums* do not only produce their fruit on the last year's wood, but also on spurs that come out of wood many years old. It is a common error to be too free with the knife in the winter-pruning, cutting off the extremities of all the branches; the consequence of which is, that there is too great a quantity of young shoots produced, and the fruit is small and poor.

The safest method in the management of these trees is to lay in their shoots horizontally, as they are produced, at equal distances, in proportion to the length of their leaves; and where there is not a sufficient quantity of branches to fill up the vacancies of the tree, there the shoots may be pinched in the beginning of May, which causes them to produce some lateral branches to supply those places; and during the growing season, all foreright shoots should be displaced, and such as are to remain must be regularly trained in to the wall or espalier. Miller.

All the species of *plums* have within their fruit a hard stone, within which there is contained a soft and tender kernel: this kernel contains the seminal plant, from which would be produced another tree of the same kind, if it were set in the ground; and it is very natural to suppose, that the only use of the thick stone or husk of this, was to preserve its tender substance from rotting too soon in the earth, and to give it a proper time for developing its parts, to preserve its natural oilyness during that time, and to furnish from its own substance a proper nourishment to the growing plant; for observation shews, that it finally breaks into a very fine powder.

There has not been found any species of *plum*, which had not its kernel contained in a stony coat of this kind, from whatever grafts they have been propagated; nor is there any art known by which the kernel of this sort of fruit can, while growing, be deprived of its coat.

Mr. Marchand, however, in the year 1735, shewed, before the Academy of Sciences at Paris, certain *plums*, whose kernels had no stone or shell round them; and found that they grew upon a tree which never had produced any others, and which had been known to produce such for twenty years. The kernel in these was covered with a reddish skin, which was rough to the touch; and, within that, with another which was thinner and white. The kernel had nothing particular in it, except that it carried on one side of its outer surface, and that always in the same place, a little stony prominence, more or less dented on its convex part: this is usually a twelfth of an inch broad, and two thirds of an inch long, and has no other appearance but that of a distempered part of the kernel, only that all the kernels have it.

The thick wrinkled skin which surrounds the kernel, seems in this case to supply the place of the stone or hard shell; and in this also it resembles it, that the pulp of the fruit parts easily and readily from it; and the hard oblong body, which is placed on one side of the kernel, is by no means proper for this purpose. Mem. Acad. Scienc. Par. 1735.

For the method of destroying insects in the *plum*-tree, see PEACH-*tree*.

PLUM, *American*, *black cocoa*, or *maiden*, *cherry-bottomed*, in *Botany*, a genus of the *icosandria digynia* class. Its characters are these: the empalement of the flower is of one leaf, divided into five parts, almost to the middle; the flower has five petals and ten stamina, five of which are longer than the petals, the other shorter; in the centre is situated an oval germen which becomes an oval fleshy berry, including a nut with five longitudinal furrows, and five valves. Linnæus mentions one, and Miller two species, which are natives of the warm parts of America.

PLUM, *hog*. See GUAIAVA.

PLUM, *Jamaica*, or *hog*, *spondias*, in *Botany*, a genus of the *decandria pentagynia* class. Its characters are these: the flower has five oblong spear-shaped petals, and a small permanent coloured empalement, with ten scaly obtuse nectariums, situated between the petals; and ten bristly stamina shorter than the petals, with oblong summits; the oblong germen, which is immersed in the receptacle, supports five short parallel styles, joined in a five-cornered column, crowned by a simple stigma; and afterward becomes an oblong fleshy berry, including a hard oblong nut, covered with fibres, having five cells.

The

The fruit of this sort is esteemed by some of the inhabitants of the islands in the West Indies; but as the flesh is very thin, so a great number of the *plums* will afford but little meat: however, the wild hogs are very fond of them, and it is their principal food during the season of their ripening. Linnæus enumerates two species, one of which is the *mombin*, and the other the *myrobalanus*.

PLUM, *indian date, pistumin, persimon*, or *pitchumon, diospyros*, in *Botany*, a genus of the *polygamia dioecia* class. Its characters are these: it hath hermaphrodite and male flowers on separate plants; the hermaphrodite flowers have a large, obtuse, permanent empalement, divided into four parts; the flower has one pitcher-shaped petal, cut at the brim into four segments, and eight short briftly ſtamina, firmly joined to the empalement; in the centre is ſituated a roundiſh germen, ſupporting a ſingle quadriſid ſtyle, crowned by an obtuſe bifid ſtigma; the germen becomes a large globular berry, with cells, each including one oblong, compreſſed, hard ſeed; the male flowers have the ſame calyx and flower, with eight ſhort ſtamina, but have no germen. There are two ſpecies.

PLUMAGE, the feathers, or covering of birds. For the mechaniſm wherein, ſee FEATHER.

PLUMAGE, in *Falconry*, is particularly underſtood of the feathers under a hawk's wing.

The falconers alſo give their hawks parcels of ſmall feathers to make them caſt; and theſe they call *plumage*.

PLUMB, or PLUM, in matters of ſpicery. See CURRANTS and RAISINS.

PLUMB-LINE, a term among artificers for a PERPENDICULAR *line*.

It is thus called, becauſe uſually deſcribed by means of a plumbet.

PLUMBAGO, in *Metallurgy*, a metalline recrement, ſeparated in the purification of gold or ſilver with lead, and ſticking to the ſides of the furnace.

This is otherwiſe called *molybdæna*; and has the ſame virtue with litharge.

PLUMBAGO ſeems alſo to have been uſed, among the *Ancients*, for *black* LEAD, uſed in making pencils for deſigning, &c.

Pomet adds, that *plumbago* was alſo the ſea-lead, *plumbum marinum*, of the ancients; who, he notes, took black lead for a production of the ſea, not a mineral, as it really is: but this is ſcarce credible.

PLUMBAGO, in *Botany*. See LEAD-*wort*.

PLUMBAGO, in the *Hiſtory of the Gems*, a word uſed by the Roman authors to expreſs a blemiſh common to their worſe kinds, and greatly debaſing their value. It was a ſort of bluiſh or blackiſh deadneſs in the ſtone, which mixed itſelf with the other colour, be that what it would, and rendered it dull and dead. The emerald was of all the gems the moſt ſubject to this fault; and, in this caſe, its fine green colour was always rendered cloudy and bluiſh; and in ſome lights the ſtone appeared of a dusky greyiſh blue, with no green at all in it. The Bactrian emeralds, which were in great eſteem with the ancients, were often ſubject to this imperfection; and thoſe of Cyprus, taken out of the copper-mines, though ſubject to many other imperfections, were uſually quite free from this.

PLUMBAGO, in *Mineralogy*, a name given by many authors to a ſort of foſſil, having very much the appearance of a lead-ore, but not ſuch in reality.

It is called alſo GALENA, BLINDE, and *mock-lead*. It is uſually of a plated texture, and dark blackiſh blue colour, like the lead-ores; but on trial it yields no metal.

PLUMBATÆ, among the *Romans*, a kind of ſcourge, the thongs of which were armed with leads.

PLUMBATÆ likewiſe ſignified leaden balls, uſed by ſoldiers to annoy the enemy with; whence the ſoldiers were called *mamubarbuli*.

PLUMBERY, formed of *plumbum*, *lead*, the art of caſting, preparing, and working LEAD; and of uſing it in buildings, &c.

The lead uſed in *plumbery* is furniſhed from the lead-works in large ingots, or blocks, called pigs of lead, ordinarily weighing about a hundred pounds a-piece.

As this metal melts very eaſily, it is eaſy to caſt figures hereof, of any kind, by running it into moulds of braſs, clay, plaiſter, &c. But the chief article in *plumbery*, is the ſheets, and pipes of lead. They are theſe which make the baſis of the plumber's work in building; the process of theſe, therefore, we ſhall give a deſcription of.

Method of making large ſheets of lead. The lead deſtined for this uſe is melted in a large caldron or furnace, uſually built with free-ſtone and earth, fortified on the outſide with a maſſive of ſhards and plaiſter. At the bottom hereof is a place ſunk lower than the reſt, wherein is diſpoſed an iron pot, or pan, to receive what may remain of the metal after the ſheet is run. The furnace is ſo raiſed above the area of the floor, as that the iron pot juſt reſts thereon.

To uſe the furnace, they heat it with wood laid within it; that done, they throw in the lead at random with the burning-coals, to melt.

Near the furnace is the table or mould, whereon the lead is to be caſt. This conſiſts of large pieces of wood, well jointed, and bound with bars of iron at the ends. Around it runs a frame, conſiſting of a ledge or border of wood, two or three inches thick, and one or two high from the table, called the *ſhorps*. The ordinary width of the tables is from three to four feet; and their length from eighteen to twenty feet.

This table is covered with fine ſand, prepared by moiſtening it with a watering pot, then working it with a ſtick; and at laſt, to render it ſmooth and even, beating it flat with a mallet, and planing it with a flip of braſs, or wood.

Over the table is a ſtrike or rake of wood, which bears and plays on the edges of the frame, by means of a notch cut in either end thereof: and is ſo placed, as that between it and the ſand is a ſpace proportionable to the intended thickneſs of the ſheet. The uſe of this ſtrike is to drive the matter, while yet liquid, to the extremity of the mould.

At top of the table is a triangular iron peel or ſhovel, bearing, before, on the edge of the table *itſelf*, and behind, on a treſſle ſomewhat lower than the table. Its uſe is in conveying the metal into the mould; and the deſign of its oblique diſpoſition is, that it may by that means be able to retain the metal, and keep it from running off at the fore-ſide, where it has no ledge. Some of theſe peels are big enough to hold fifteen or ſixteen hundred weight of lead, and even more.

Things being thus diſpoſed, with a large iron ladle they take out the melted lead, coals and all, out of the furnace; and with this, mixed as it is, they fill the iron peel. When full, they take out the coals, and clear the lead with another iron ſpoon, pierced after the manner of a ſcummer.

This done, they hoiſt up the lower part of the peel by its handle; upon which the liquid matter running off, and ſpreading itſelf on the mould, the plumber conducts and drives it to the extremity of the table, by means of the ſtrike, which the workman paſſes along the ledges, and thus renders the ſheet of an equal thickneſs.

The ſheets thus caſt, there remains nothing but to edge them. i. e. to planiſh the edges on both ſides, in order to render them ſmooth and ſtrait.

Method of caſting thin ſheets of lead. The table or mould here uſed is of a length or breadth at diſcretion, only ledged on one ſide. Inſtead of ſand, they cover it with a piece of woollen ſtuff, nailed down at the two ends, to keep it tight; and over this they lay a very fine linen cloth. The feet of the table are uneven, ſo that it does not ſtand horizontal, but moderately inclined.

Great regard is, in this proceſs, had to the lead while melting, that it have the juſt degree of heat, ſo as it may run well, yet not burn the linen. This they judge of by a piece of paper; for if the paper take fire in the liquid lead, it is too hot; and if it be not ſhrunk and ſcorched a little, it is not hot enough.

Being then in its juſt degree, they have a ſtrike, but different from that deſcribed in the former article; as ſerving both for peel and ſtrike; both to contain and to conduct the liquid lead. It is, in effect, a wooden caſe without any bottom, only cloſed on three ſides. It is pretty high behind, but the two ſides, like two acute angles, ſtill diminiſh to the tip, from the place where they are joined to the third or middle piece, where they are of the ſame height therewith: viz. ſeven or eight inches high. The width of the middle makes that of the ſtrike, which again makes that of the ſheet to be caſt.

The ſtrike is placed at top of the table, which is before covered in that part, with a paſteboard, that ſerves as a bottom to the caſe, and prevents the linen from being burnt while the liquid is pouring in. The ſtrike is ſo diſpoſed on the table, as that the higheſt part looks to the lower end of the table, and the two ſloping ſides to the higher end.

The ſtrike is now filled with lead, according to the quantity to be uſed; which done, two men, one at each ſide the table, let the ſtrike deſcend down the table, or elſe draw it down with a velocity greater or leſs, as the ſheet is to be more or leſs thick; the thickneſs of the ſheet ſtill depending on the promptitude wherewith the ſtrike ſlides down the inclining mould.

The fine ſmooth ſheets of lead, thus made, are ſometimes uſed between the joints of large ſtones in great buildings, &c.

Method of caſting pipes, without ſoldering. To make theſe pipes, they have a kind of furnace, conſiſting of a large

iron pot or caldron, supported on a pretty high iron stand. The caldron is encompassed with a massive of bricks and loam; only leaving a mouth or passage for the conveyance of wood underneath, and for lighting the fire; and another little aperture behind, to serve as a vent-hole. In this furnace they melt the lead, after first heating it with a fire underneath: to forward the fusion, they also put in burning faggots along with the metal. The metal is afterwards skimmed, and laded off with the instruments mentioned above. Near the furnace is a bench furnished at one end with a little mill, with arms or levers to turn it with. A strong girt, armed with an iron hook at one extremity, is fastened by the other to the axis of the mill, around which it turns when in motion. On this bench the moulds of the pipes are placed horizontally, and the mill and the girt serve to draw out the iron core, after the pipe is cast.

The moulds of these tubes are of brass, and consist of two pieces, which open and shut by means of hooks and hinges: their inward caliber, or diameter, is according to the size of the pipe to be made, and their length is usually two feet and a half. In the middle is placed a core, or round piece of brass or iron, somewhat longer than the mould, and of the thickness of the inner diameter of the pipe. This core is passed through two copper rundles, one at each end of the mould, which they serve to centre; and to these is joined a little copper tube about two inches long, and of the thickness the leaden pipe is intended to be of. By means of these tubes the core is retained in the middle of the cavity of the mould. The core being in the mould, with the rundles at its two ends, and the lead melted in the furnace, they take it up in a ladle, and pour it into the mould, by a little aperture at one end, made in form of a funnel.

When the mould is full, and the metal cold, they pass the hook of the girt into a hole at the end of the core; and turning the mill with the hand, draw out the core. They then open the mould, and take out the pipe.

If they desire to have the pipe lengthened, they put one end thereof in the lower end of the mould, and pass the end of the core into it; then shut the mould again, and apply its rundle and tube as before. The pipe just cast serving for rundle, &c. at the other end.

Things thus replaced, they pour in fresh metal into the mould, thus repeating the operation, till they have got a pipe of the length required.

Pipes made of sheet lead soldered. For these the *plumbers* have wooden cylinders or rollers, of the length and thickness required; and on these they form their pipes, by wrapping the sheet around them; soldering up the edges all along in this manner. After grating the lead well with a grater, they rub resin over the part thus grated; they then pour on it some solder melted in a ladle, or else melt it with a hot soldering iron, smearing those parts where they would not have the solder catch, with chalk, or the soil of the hand.

The solder which the *plumbers* use, is a mixture of two pounds of lead with one of tin. See SOLDER.

PLUMBING, among *Miners*, a term used to express the using a mine dial, in order to know the exact place of the work where to sink down an air-shaft, or to bring an adit to the work, or to know which way the load inclines when any flexure happens in it.

It is performed in this manner: a skilful person with an assistant, and with pen, ink, and paper, and a long line and a sun-dial, after his guess of the place above ground, descends into the adit or work, and there fastens one end of the line to some fixed thing in it; then the inclined needle is let to rest, and the exact point where it rests is marked with a pen: he then goes on farther in the line still fastened, and at the next flexure of the adit he makes a mark on the line by a knot or otherwise; and then setting down the dial again, he there likewise notes down that point at which the needle stands in this second position. In this manner he proceeds from turning to turning, marking down the points, and marking the line till he comes to the intended place; this done, he ascends, and begins to work on the surface of the earth what he did in the adit, bringing the first knot in the line to such a place where the mark of the place of the needle will again answer its pointing, and continues this till he comes to the desired place above ground, which is certain to be perpendicularly over the part of the mine into which the air-shaft is to be sunk.

PLUMBUM. See LEAD.

PLUMBUM *cornutum*, called also *Saturnus cornutus*, in *Chemistry*, is a metallic salt, formed by the precipitation of lead from its solution in nitrous acid with the marine acid, and all the neutral salts which contain it. It is thus called from its resemblance to the LUNA *cornea*. This salt may be made by other methods, and particularly by disengaging the volatile alkali from sal ammoniac by lead. In this way Mr. Margraaf makes the *plumbum cornutum*, which he employs in the preparation of PHOSPHORUS. See LEAD.

PLUMBUM *igneum*. See *Butter* of LEAD.

PLUME, a set or bunch of stitch feathers, pulled out of the tail and wings, and made up to serve for ornament in funerals, &c.

PLUME, formed of *pluma*, *feather*, in *Falconry*, is the general colour or mixture of the feathers of a hawk, which shews her constitution.

When a hawk forms her pens, and diminishes it of its feathers, she is said to *plume* her.

PLUME, or PLUMULE, in *Botany*, a little member of the grain or seed of a plant; being that which in the growth of the plant becomes the stem or trunk thereof. See SEED, and SPERM.

The *plume* is formed in a cavity formed in the lobes on purpose for its reception. It is almost of the same colour with the radicle, or little root, on the hams whereof it is fastened.

The *plume* is the first part that appears out of the earth, as, in effect, it is the part that first appears out of the membrane, or cover of the seed; there being a hole over-against it in the membrane, through which it makes its escape.

It is the appearance of the *plume* without the cavity of the grain, that makes what we call the *bud* or *germ* of a plant.

The *plume* is so called, because consisting of several pieces bound together in manner of a feather. In corn, the *plume* is that, which, after the ravicle is first forth, shoots out towards the smaller end of the seed; whence some call it the *acrospire*.

PLUME-*alum*, *plumose plumbosum*. See ALLUM.

PLUMERIA, in *Botany*. See *Red* JASMINE.

PLUMMER'S *Pills*. This medicine is composed of the sulphur auratum antimonii and cinnabar, commonly in equal parts, eight of each three grains; but this may be varied occasionally, according to the physician's direction. These two powders must be well levigated together, by which the bright red colour of the sulphur is changed into a dusky brown; afterwards, add two drams of the extract of liquorice; and so much gum arabic, as sufficient quantity of the mucilage of gum arabic, may be made into pills. We refer to the learned Essays of *Edinburgh* for the dose, regimen to be observed, and effects of this medicine; as also for the manner of preparing the sulphur of antimony according to Angelus Sala, which is said to be preferable to the common method. See Med. Ess. Edinb. abridg. vol. i. p. 205. vol. ii. p. 435.

This medicine has been found greatly beneficial in cutaneous eruptions, and is said to have completed a cure after salivation has failed, in venereal infections, and in gleets remaining after the cure of a gonorrhœa. It operates by carrying off the excrements of distempers by insensible perspiration or sweat. It has also been found successful in obstinate glandular swellings; two or three pills of an ordinary size may be taken night and morning, the patient keeping moderately warm, and drinking after each dose a draught of the decoction of the woods, or of sarsaparilla.

PLUMMET, PLUMB-RULE, or PLUMB-LINE, an instrument used by masons, carpenters, &c. to draw perpendiculars; in order to judge whether walls, &c. be upright, planes horizontal, and the like.

It is thus called from a piece of lead, *plumbum*, fastened to the end of a thread or cord, which usually constitutes this instrument.

Sometimes the string descends along a ruler of wood or metal ruled perpendicularly on another; in which case it becomes a level.

At sea a *plummet* is used by the pilot to sound the depth of the water.

PLUMOSE *antennæ*, in *Natural History*, a term used to express the *antennæ*, or horns of certain moths and butterflies, which are formed in the manner of feathers, being composed of a stem and fibres issuing on each side from it: these are jointed and moveable any way; and even the small fibres, at their sides, are jointed at their bottom, and are moveable, but they move all together. See PETTINE.

PLUNDER, in *Sea-Language*, a name given to the effects of the officers or crew of a prize, which are pillaged by the captors.

PLUNGE, in the *Manege*. See EXTRAVAGANT.

PLUNGER, in *Mechanics*, a solid brass cylinder used as a FORCER in *forcing* PUMPS.

PLURAL, *plurale*, in *Grammar*, a particular inflexion of nouns and verbs, whereby they come to express a plurality or number of things.

The Latins, English, &c. have only two numbers, *singular*

sular and *plural*; the Greeks and Hebrews have three, *singular*, *dual*, and *plural*.

In Latin, &c. both nouns and verbs have usually diſtinct terminations to their different numbers; in Engliſh, nouns ſubſtantives uſually become *plural* by the addition of *s* or *es* to the ſingular.

Nouns adjective are the ſame in both numbers; and in verbs, the number is diſtinguiſhed by that of the pronoun.

PLURALITY, *pluralitas*, a diſcrete quantity, conſiſting of two, or a greater number.

A plurality of worlds is a thing which Mr. Huygens has endeavoured to prove in his Coſmotheoros. And the ſame is likewiſe contended for in a very pretty treatiſe of M. Fontenelle under that title.

See the chief argument for a *plurality* of worlds under HEAVEN, PLANET, and EARTH.

The greateſt abſurdity in the pagan theology, is the *plurality of gods*.

PLURALITY *of benefices, or livings*, is where the ſame clerk is poſſeſſed of two or more ſpiritual preferments, with cure of ſouls. See BENEFICE.

Plurality of benefices is a thing too much tolerated in the church, but never approved of.

It was the frailneſs of ſome beneficed that firſt gave occaſion to *pluralities*; for an eccleſiaſtic, not being able to ſubſiſt on a ſingle one, was allowed to hold two; and at length the number increaſed without bounds.

The abuſe was endeavoured to be remedied at the council of Lateran, under Alexander III. and Innocent III. in the year 1215, when the holding more than one benefice was expreſſly forbid by a canon, under the penalty of deprivation; but the ſame canon granting the pope a power to diſpenſe with it in favour of perſons of diſtinguiſhed merit, there were ſo many found a title to this merit, that the prohibition became uſeleſs.

Pluralities were alſo reſtrained by ſtatute 21 Hen. VIII. cap. 13. which enacts, that if any perſon, having one benefice with cure of ſouls, of the yearly value of 8*l.* or above (in the king's books), accept any other with cure of ſouls, the firſt benefice ſhall be adjudged in law to be void, &c. though the ſame ſtatute provides for diſpenſation in certain caſes. See CHAPLAIN.

In order to procure a diſpenſation, the preſentee muſt obtain of the biſhop, in whoſe dioceſe the livings are, two certificates of the values in the king's books, and the reputed values and diſtance of ſuch livings; one certificate for the archbiſhop, and the other for the lord chancellor. And if the livings lie in two dioceſes, then two certificates of the ſame kind are to be obtained from each biſhop. He muſt alſo exhibit to the archbiſhop his preſentation to the ſecond living; and bring with him two papers of teſtimonials from the neighbouring clergy concerning his behaviour and converſation, one for the archbiſhop, and the other for the lord chancellor; and he muſt alſo exhibit to the archbiſhop his letters of orders of deacon and prieſt, and a certificate of his having taken the degree of maſter of arts at the leaſt, in one of the univerſities of this realm, under the hand of the regiſter of ſuch univerſity. And in caſe he be no doctor or bachelor of divinity, nor doctor of law, nor bachelor of canon law, he is to procure a qualification of a CHAPLAIN, which is to be duly regiſtered in the faculty office, in order to be tendered to the archbiſhop, according to the ſtatute. And if he hath taken any of the aforeſaid degrees, which the ſtatute allows as qualifications, he is to procure a certificate thereof as already mentioned, and to exhibit the ſame to the archbiſhop; after which his diſpenſation is made out at the faculty office, where he gives ſecurity according to the direction of the canon. Afterwards he muſt repair to the lord chancellor, for confirmation under the broad ſeal; and then he is to apply to the biſhop of the dioceſe where the living lies, for his admiſſion and inſtitution. By the ſeveral ſtamp acts, for every ſkin, or paper, or parchment, &c. on which any diſpenſation to hold two eccleſiaſtical dignities or benefices, or a dignity and a benefice, ſhall be engroſſed or written, there ſhall be paid a treble forty ſhilling ſtamp duty.

We have alſo a regulation in regard to *pluralities*, but it is often diſpenſed with; for, by the faculty of diſpenſation, a pluraliſt is required, in that benefice from which he ſhall happen to be moſt abſent, to preach thirteen ſermons every year, and to exerciſe hoſpitality for two months yearly.

In Germany the pope grants diſpenſations for poſſeſſing a *plurality of benefices*, on pretence that the eccleſiaſtical princes there need large revenues to beat up againſt the proteſtant powers.

PLURIES, a writ that iſſues in the third place after two former writs have been diſobeyed; for firſt goes out the original writ or *capias*, which, if it has no effect, then iſſues the *alias*; and if that alſo fails, then the *pluries*. Old Nat. Br. 33.

It is uſed in proceedings to OUTLAWRY, and in great diverſity of caſes. Tabl. Reg. Writs.

PLUS, in *Algebra*, a term commonly uſed for *major*, or *magis*, *more*; denoted by the CHARACTER +.

Thus 4 + 10 = 14, is read, four, *plus*, or more, 10, is equal to 14.

PLUSH, in *Commerce*, &c. a kind of ſtuff having a ſort of velvet nap or ſhag on one ſide; compoſed regularly of a woof of a ſingle woollen thread, and a double warp, the one wool, of two threads twiſted, the other goats or camels hair; though there are alſo ſome *plushes* entirely worſted, and others compoſed wholly of hair.

Plush is manufactured like velvet, on a loom with three treadles. Two of theſe ſeparate and depreſs the woollen-warp, and the third raiſes the hair-warp; upon which the workman throwing the ſhuttle, paſſes the woof between the woollen and hair-warps; and afterwards laying a braſs broach, or needle, under that of the hair, he cuts it thereon with a knife deſtined for that uſe, conducting the knife on the broach, which is made a little hollow, all its length; and thus gives the ſurface of the *plush* an appearance of velvet.

Some aſcribe the invention of *plush* to the Engliſh; others ſay it was firſt made in Holland, and particularly at Haerlem. Be this as it will, it is certain, the French are the people who make the moſt of it; there being ſeveral very conſiderable *plush* manufactures at Amiens, Abbeville, and Compeigne.

There are other kinds of *plush*, all of ſilk; ſome of which have a pretty long knap on one ſide, and ſome on both.

PLUSH, among *Botaniſts*, is a name given to the middle of *roſes*, *anemonies*, &c. called alſo *thrum*, or *thrummy heads*; by others, *hairy heads*, *buttons*, *boſs*, *tuft*, or *wart*. This is properly the STAMINA of the flower.

PLUTEI, in the Roman *Art of War*, were engines contrived for the defence of ſoldiers, conſiſting of the ſame materials with the VINEÆ, but of a different figure; being ſhaped like an arched ſort of waggon, and having three wheels, ſo conveniently placed, that the machines would move either way with equal eaſe.

PLUTO, in *Mythology*, the ſon of Saturn and Rhea, and ſovereign of the empire of darkneſs. Statius calls him the black Jupiter; and he is repreſented by the poets as holding his ſceptre in his hand, with a veil over his head, which, as well as his complexion, ſhould be dark and terrible. He is ſometimes called by the name of Dis.

PLUTUS, in *Mythology*, the god of riches, reckoned amongſt the number of infernal deities, becauſe riches are derived from the bowels of the earth. Heſiod makes him to be a deſcendant of Ceres and Jaſon in the iſle of Crete, probably becauſe theſe two perſons applied themſelves to agriculture, which is the means of obtaining the moſt ſubſtantial riches. *Plutus* had a ſtatue at Athens, placed in the temple of Minerva, where the public treaſures were depoſited; at Thebes, in the temple of Fortune, this goddeſs holds *Plutus* in her arms as an infant, nouriſhed by her; and at Athens *Plutus* is in the arms of the ſtatue of Peace, as the ſymbol of riches, which give peace.

PLUVIAL, *pluviale*, anciently ſignified a hood or cloak; which eccleſiaſtics, chiefly religious, wore in the country, to ſhelter themſelves from the rain; by the Latins called *pluviales cucullæ*.

The word is now uſed, in the Romiſh church, for a large hood worn by the chanter and ſubdeacon, at maſs and veſpers, &c. It covers the whole man, and is fixed before with two claſps.

PLUVIALIS, in *Ornithology*. See PLOVER.

PLUVIALIS *major*, in *Ornithology*, a name given by ſome authors to the LIMOSA, a bird in ſome reſpects reſembling our reſtſnark, but larger and longer legged.

This bird is alſo called the *glottis* and *totanus*.

PLUVIALIS *ſecunda*, in *Ornithology*, a name given by many to the common green *wood-pecker*, the *picus viridis* of authors, called alſo in Engliſh the *rain-fowl*, from an obſervation of its always being moſt clamorous when rain is coming on.

PLUVIUS, in *Antiquity*, an attribute of JUPITER; implying him the author of rain; q. d. he that ſends rain.

Among the baſſo relievos of the Antonine column, in the place where the miracle of the thundering legion is repreſented, we ſee a flying man in the air, his arms ſpread out, and with a very long beard, which ſeems to diſſolve into rain. The learned take this to be a repreſentation of Jupiter Pluvius.

PLYERS, in *Fortification*, denote a kind of balance uſed in raiſing or letting down a *draw-bridge*. They conſiſt of two timber levers, about twice the length of the bridge they fall, joined together by other timbers framed

in the form of a St. Andrew's cross, which serves as a counterpoise. They are supported by two upright jambs, on which they swing; and the bridge is raised or let down by means of chains joining the ends of the *pipes* and bridge.

PLYING, in *Sea-Language*, is the art of making, or endeavouring to make, a progress against the direction of the wind.

Plying is also used by ferrymen to denote their waiting for a fare.

PLYMOUTH *marble*, among our *Artificers*, a term used for a sort of *marble* dug in great plenty about Plymouth, and in some parts of Devonshire, where it lies in very thick strata, and whence it is brought in large quantities to us; and when wrought looks little less beautiful than some of the Italian *marble*.

It is very hard and firm, and of a beautiful texture; its ground is a bluish white, and its variegations are principally a pale red, and in smaller quantities brown and yellow; these lie in very orderly beds, and often there is a very agreeable glow of a faint red diffused through the whole substance. It is remarkably even in its whole structure, and is therefore capable of a more than ordinarily elegant polish.

PLYNTERIA, Πλυντηρια, in *Antiquity*, a festival in honour of Aglaurus, the daughter of king Cecrops, or rather of Minerva, who had from that lady the name of Aglaurus.

For the ceremonies observed at this solemnity, see Potter, Archæol. Græc. lib. ii. cap. 20. tom. 1. p. 425.

PNEUMA, Πνευμα, in Hippocrates, sometimes imports spirit, air, or vapour, and frequently it signifies the breath, that is, the air drawn in by inspiration, and expelled during expiration. But *pneuma*, by the above quoted author, is often used to express a difficult, short, and laborious respiration.

PNEUMATICS, *pneumatice*, called also PNEUMATOLOGY and PNEUMATOSOPHY, the doctrine and contemplation of spirits, and spiritual substances.

The word is formed of the Greek πνευμα, *spiritus*, *breath*; whence, from the different acceptations of that word either as an incorporeal substance, or as air, there arise two sorts of *pneumatics*.

PNEUMATICS, in the *Schools*, is frequently used for the doctrine of spirits: as God, angels, and the human soul. See SPIRIT.

In this sense *pneumatics* coincide with what we otherwise call METAPHYSICS.

PNEUMATICS is more commonly used, among us, for the doctrine of the air; or that part of natural philosophy which treats of the nature, properties, and effects of the air.

Some make *pneumatics* a branch of mechanics; because it considers the air in motion, with the effects thereof. It is certainly a sister of hydrostatics; the one considering air in the same manner that the other does water. Wolfius, in lieu of *pneumatics*, uses the word *aerometry*, q. d. the art of *measuring the air*.

The doctrine and laws of *pneumatics* will be found under AIR, ATMOSPHERE, ELASTICITY, GRAVITY, COMPRESSION, CONDENSATION, RAREFACTION, EXPANSION, &c.

PNEUMATIC *engines*, *machines* or *utensils* PNEUMATICA, denotes the AIR-PUMP.

PNEUMATOCELE, Πνευματοκηλη, formed from πνευμα, *wind*, and κηλη, *tumor*, in *Medicine*, a flatulent or windy HERNIA; or a tumor of the membranes of the scrotum or navel, proceeding from pent up vapours, and attended with a tensive pain.

Sometimes one of the testes only is thus inflated, sometimes both, and sometimes likewise the scrotum.

This *hernia* is of all others the lightest, and least dangerous. Mr Pott objects to the propriety of the appellation *pneumatocele*, or *wind-rupture*, and maintains that there is no hernia produced by mere wind. The two diseases, he says, which in new-born children and infants are taken for and called wind-ruptures, are, a rumor produced by a small quantity of fluid remaining in the lower part of the tunica vaginalis, after its communication above with the cavity of the belly is closed; and a true, but small, *intestinal* HERNIA. Chirurgical Works, vol. ii. p. 422.

It is cured by discutients internally, and fomentations and cataplasms externally.

PNEUMATODES, a word used by Hippocrates to express a person who fetches his breath short and quick; and sometimes for one who has his belly or ilia much distended by flatulencies. *Pneumatias* is also used in the same double sense.

PNEUMATOMACHI, Πνευματομαχοι, ancient heretics, so called, because they opposed the divinity of the Holy Spirit, placing him in the number of creatures.

PNEUMATOMPHALOS, a word used by Hippocrates to express a person who has a windy or flatulent rupture of the navel.

PNEUMATOSIS, Πνευματωσις, a term which some authors use for the generation or formation of animal spirits in the brain.

PNEUMONANTHE, in *Botany*, a name given by many botanical writers to a species of GENTIANA, called also by some the *italian* violet.

PNEUMONICS, Πνευμονικα, medicines proper in diseases of the lungs, in which respiration is affected.

The word is formed from the Greek πνευμων, *lungs*, or πνευμα, *spiritus*, *breath*.

Of this number are sulphur, lung-wort, hyssop, groundivy, and coltsfoot; they are used in phthises, asthmas, peripneumonies, pleurisies, &c.

PNIGITIS *terra*, in the *Materia Medica of the Ancients*, a name given at different periods of time to two different species of earth; the *terra pnigitis* of Dioscorides and Pliny being a grey marle, and the *pnigitis* of Galen a black clay.

The last of these is a very valuable astringent, and is found in many parts of this kingdom, particularly in the neighbourhood of London, and well deserves to be introduced into the practice of physic.

PNIGMOS, from πνιγω, *I suffocate*, in *Medicine*, any kind of suffocation, from whatever cause; it is very often used to express that of hysteric kind in women.

PNIX, a word used by physicians to express the suffocation from hysteric fits, or any other cause.

POA, in *Botany*, the name of a genus of plants of the grass kind, belonging to the class and order of *triandria digynia*; the characters of which are, that the calyx is a glume composed of two valves, containing several flowers disposed in a two-rowed oval, or oblong spike; the valves oval and pointed, but without awns; the flower is composed of two oval and pointed valves; these are hollowed, compressed, a little longer than the valves of the cup, and without beards or awns; the stamina are three capillary filaments; the antheræ are split at their ends; the germen of the pistillum is roundish; the styles are two, reflex and hairy; the stigmata are hairy also; the flower adheres closely to the seed, and does not open to let it out; the seed is single, oblong, and pointed at both ends, and somewhat flatted. There are twenty-five species enumerated by Linnæus. See GRASS.

POAKE-*root*, in Virginia, is used to denote the solanum bacciferum. The Indians use it for a purge, though commonly deemed a poison. Phil. Trans. N° 454. § 1.

POCATSJETTI, H. M. in *Botany*, the name of a small shrub which grows in Malabar. The leaves powdered, and sprinkled upon ulcers, repress luxuriant and fungous flesh; and taken internally, they excite a sweat, and diminish the paroxysm of an intermitting fever.

Of the bark and root, powdered, and mixed with oil, an unguent is made, said to be good for the itch, and other cutaneous disorders.

POCCOON, in *Botany*. See PUCCOON.

POCHARD, in *Ornithology*, the name of a species of wild-duck, called by some the *penelope* and *rutila*, and by many in English the red-headed *widgeon*.

It is larger than the common *widgeon*, and is shorter and thicker bodied.

POCK. See POX.

POCK-*wood*. See GUAIACUM.

POCKET-*sheriffs*, in *Law*, sheriffs nominated by the sole authority of the crown. See SHERIFF.

POCKET *of wool*, is half a sack. See SACK *of wool*.

The *pocket* contains usually twenty-five hundred weight of wool.

POCKET *instruments*, in *Surgery*, are such as a surgeon ought always to have in readiness, and may conveniently carry about him in a proper case: these are two lancets of different sizes; the one proper to open abscesses, the other smaller, for bleeding; a pair of straight scissars, useful on many occasions; a pair of crooked scissars, proper to be used in dividing fistulæ, and in several other cases; a pair of forceps with teeth at one end, to remove dressings, and upon occasion to extract splinters or thorns; these are also serviceable to the surgeon in his anatomical exercises; they are commonly made of steel, but those of silver are much neater; a razor; a straight incision knife; a crooked incision knife; a strait double-edged incision knife; a probe with one end broad and thin, proper for discovering a fissure in the cranium, and for many other uses; and the other end rounded, to examine the depth and situation of wounds and ulcers. The neatest probes are made of silver, though they are frequently made also of steel, ivory, or whalebone; a grooved probe or director, to direct the edge of the knife or scissars in opening sinuses or fistulæ, that by this means the subjacent vessels, nerves, and tendons, may remain unhurt. The upper end of this instrument, sometimes is ornamented,

and serves only for a handle; sometimes it is made in form of a spoon, to contain powder to sprinkle upon wounds or ulcers; sometimes also this is made forked at the end, to divide the frænum of the tongue; a spatula to depress the tongue, in order to examine the state of the tonsilæ, uvula, and fauces, when they are affected with any disorders: it is also used to suspend the tongue when the frænum is to be divided; for which purpose it is to be made with a fissure at its extremity, and should therefore rather be made of silver than of any other metal. Besides these, there should be an ordinary spatula for spreading plasters, ointments, and cataplasms; and sometimes by means of their fulcated extremity they are of service in raising up fractured bones of the cranium; several needles must also be kept here, some straight, and others crooked, for the stitching up of wounds, taking up of arteries, and many other uses. Heister's Surg. p. 12.

POCKET *medicines*. See MEDICINE.

POCO *allegro*, in the *Italian Musick*, is not so fast as *allegro*.

POCO *largo*, intimates to play or sing a little slow. See LARGO.

POCO *meno allegro*, is used to signify that the part it is joined to should be played or sung in a little less gay manner than *allegro* requires.

POCO *presto*, serves to let us know that we ought to sing or play that part to which it is annexed, not quite so quick as *presto* requires it should.

POCUMMA, in *Botany*, a name given by the people of Guinea to a species of plant which they use as an astringent. Their manner of taking it is very singular; for they put the leaves among their dough, and bake them into a mass with the bread, and then eat the whole together in their food. Phil. Trans. N° 232.

POD, among *Botanists*, a species of *pericarpium*, consisting of two valves, which open from the base to the point, and are separated by a membranaceous partition, from which the seeds hang by a kind of funiculus umbilicalis. It is in plain language the shell or husk of any kind of pulse. See PERICARPIUM, and SILIQUA.

PODAGRA, ποδαγρα, thus called from ποὺς, *pes*, and ἄγρα, *captura*, *seizure*, in *Medicine*, the gout in the feet.

PODAGRA *dentium*, sometimes, though with impropriety enough, is used for the TOOTH-*ache*.

PODAGRA *lini*, in *Botany*, a name given by some of the later Greek writers to *cuscuta*, or *dodder*, when found growing on the linum of flax. The Latins have called this *epithymum*, as they do the dodder growing on thyme *epithymum*; the earlier Greeks called this *linozostes*. Where this dodder takes root in a field of flax, it generally occupies many plants; and where it twines round them it causes protuberances and swellings, and has therefore been resembled to the gout on that plant.

PODAGRARIA, in *Botany*, a name given by many authors to the less wild *angelica*, called also *herba Gerardi*.

PODARIA, in the *History of Insects*, a classical name comprehending all such insects as have limbs, but no wings. Hill. See APTERA.

Of this class there are two subdivisions. 1. Such *aptera podaria* as have oblong bodies with numerous legs, or more than six pair: these are the *oniscus*, or gally-worm; the *scolopendra*, or *centipes*; and the *onisci*, or wood-louse. 2. The *aptera podaria* with shorter bodies, and less numerous legs, or fewer than six pair. This subdivision contains numerous genera, as the pediculi, the podura, or puceron, the prediculi of various kinds, the monoculi, the acari, the aranei, the scorpio, and a great many others. See GALLY-*worm*, SCOLOPENDRA, &c.

PODERIS, ποδηρης, from ποὺς, *pes*, and ἀειρω, *apto*, in *Antiquity*, a robe hanging down to the feet; but it is chiefly used to express a linen garment, a surplice, a shirt. The Jewish priests were covered with this kind of long surplices, during the time of their attendance in the temple; and this was the proper habit of their order.

PODESTA, or POTESTA, a magistrate, or officer of justice and policy, in a free city.

The name is originally Italian, *podesta*; and is chiefly applied to certain magistrates of Venice and Genoa, whose function is to administer justice in those republics.

The *podesta* in Venice corresponds to the prætor in ancient Rome, though appeals lie from his decisions to the new auditors, or the new civil quaranty. See QUARANTIA.

PODEX, in *Anatomy*, &c. the same with ANUS, or *fundament*.

POINCETS, in *Ornithology*, a name given by many to the several kinds of *colymbi*, or *divers*, as they are also called in English *web-feeted*; from their legs being placed very backward on their bodies, by which means they have great advantages in swimming and diving.

PODISMUS, ποδισμος, among the Greeks, a certain space, or number of feet laid out by surveyors; it was the same with what the Romans called PEDATURA.

PODIUM; in the *Theatre of the ancients*, the wall that separated the ORCHESTRA from the SCENE. Mem. de l'Acad. vol. i. p. 190.

PODOMETER, or PEDOMETER. See PEDOMETER.

PODONIPTÆ, formed from πους, ποδος, *foot*, and νιπτω, *I wash*, a name given to some of the rigid ANABAPTISTS, who enjoin it as an obligation upon the members of their community to wash one another's feet, in compliance with the example of Christ.

PODOPHYLLUM. See DUCK's *foot*.

PODURA, in *Natural History*, a genus of the *aptera* insects. Its characters are, that it has six feet formed for running; that it has two octonous eyes, a bifurcated inflexed tail, formed for leaping, and long setaceous antennæ. There are fourteen species. See PUCERON.

PŒANOPSIA, παιανοψια, in *Antiquity*, a name sometimes given to the festival PYANEPSIA.

POEM, *poema*, ποιημα, a composition in verse, of a due length and measure.

POEMS, *carmina*, are of various kinds; some denominated from the persons who first invented, or most used them; as the *Archilochian*, *Sapphic*, &c. Others from their composition, as the *monocolon*, consisting of one kind of verse; *dicolon*, of two; and *tricolon*, of three kinds. Others from their entireness or deficiency; as *brachycatalectic*, which in every verse wants two syllables; *catalectic*, which wants one; *acatalectus*, none; and *hypercatalectus*, which has a syllable too much, which, if cut off at the beginning of the next verse, the verse is said to be *hypermeter*. See ACATALECTIC, &c. Others are denominated from the subject matter; as the *apobaterion*, *epibaterion*, *epinicion*, *epithalamium*, *genethliac*, *propemptic*, *elegiac*, *satiric*, *epicedion*, *epitaph*, *threnne* or *lamentation*, *encomiastic*, *panegyric*, *satiric*, *lyric*, *pastoral*, &c. Others from the manner of narration; as *exegetic*, which relates a thing under the author's own person, *dramatic*, and *epic*. See each under its proper head, EPIC, DRAMA, &c. To these may be added, odes, eclogues, and idyllums.

To this head must also be referred several other poetical compositions of a less serious kind, which the idly-labouring vein of little poets has produced into the world, and which, though frequently admired by persons of a low taste, are justly ranked by Mr. Addison in the class of false wit. Such are the acrostic enigma, anagram, tecto, chronogram, proteus, echo, &c.

POENITENTES, in the church of Rome, a designation given to heretics, who being admonished by the ecclesiastical judge, have abjured their errors, and given sufficient satisfaction to the bishop or inquisition. Confiscation of goods is a punishment common to all heretics; but if they confess and abjure of their own accord, without being formally prosecuted, this part of their punishment is usually remitted. See INQUISITION.

POEROU, in *Natural History*, a name given at Otaheite in the South Seas to the *bombyx tiliaceus* of Linnæus, of the bark of which they make matting, coarse cloth, and ropes and lines from the thickness of an inch to the size of a small packthread. Hawkesworth's Voyages, vol. ii. p. 217.

POESY, *poesis*. See POETRY.

The word is formed from the Greek ποιησις, of ποιεω, *facio*, *fabricor*, *fingo*, *I make*, *I frame*, *I invent*.

Hence alchemy, or the art of making gold, was anciently called *poesy*, *chrysopoesy*, &c.

POET, *poeta*, an author who composes poems, or discourses in verse.

Cicero relates it as a saying of Democritus and Plato, that there could be no good *poet sine afflatu furoris*, *without a tincture of madness*; and Aristotle calls *poets* expressly, *maniosi*, *maniacs*, *madmen*.

M. Spanheim tells us, that the Arab authors are more poetically given than those of any other people: and adds, that there are more verses among the Arabians than among all the other nations of the world put together.

The Greek word ποιητης, *poet*, signifies *author*, from ποιεω, *facio*, *I make*; whence the *poets* were anciently also called *vatides*.

By a law of the emperor Philip, inserted in the Code, lib. x. tom. iii. *poets* are expressly excluded from the immunities granted the professors of all other sciences.

Homer, Virgil, Milton, and Tasso, are the chief, almost the only epic *poets*. Sophocles, Euripides, Shakspeare, Otway, Corneille, and Racine, are the best tragic *poets*. Aristophanes, Menander, Plautus, Terence, Fletcher, Johnson, Moliere, &c. the chief comic *poets*. Horace, Cowley, Matherbe, and Rousseau, excelled as lyric *poets*. And Juvenal, Persius, Regnier, Boileau, Dryden, and Oldham, as Latine *poets*.

POET,

POET, *laureat.* See LAUREAT.

POETS, *provençal.* See PROVENÇAL, and TROUBADOURS.

POETICAL, whatever is something that relates to poetry or poets. In this sense we say, a *poetical* genius, a *poetical* phrase, *poetical* licences, *poetical* fury, &c.

Most languages have their *poetical* words, which are never used on other occasions. These prove of great advantage to the poets, who are hereby enabled to raise the style and diction into the *poetical* character, with the greater ease. The French often lament the want of a set of such words in their language, for want whereof, their poetry appears in a too familiar garb, not sufficiently distinguished from the common language. It is too reserved, not being allowed any boldness, or flights, but what might pass in prose. To this, in good measure, is attributed the little success their authors have met with in the epic way.

POETICAL *justice* is chiefly used in respect of the drama, to denote a distribution of rewards and punishments to the several persons, at the catastrophe or close of the piece, answerable to the several characters they have appeared in. See CHARACTER.

Whatever difficulties and distresses the virtuous and innocent may labour under, and how prosperously soever it may go with the wicked, in the course of the piece; the poet usually takes care to give each of them their due before he parts with them. But it is controverted whether this piece of justice be indispensable, and whether it may not be allowed to leave virtue oppressed, and vice flourishing.

POETICAL *licence.* See LICENCE.

POETICAL *numbers.* See NUMBERS.

POETICAL *rising and setting.* See RISING, and SETTING.

The ancient poets, referring the rising, &c. of the stars to that of the sun, make three kinds of rising and setting, viz. COSMICAL, ACRONICAL, and HELIACAL.

POETICS, *poetice, ars poetica*, the doctrine of poetry, or the laws and rules of conducting pieces or compositions of poetry. Aristotle's *Poetics* is a work infinitely valued; and M. Dacier's comment thereon is one of his best pieces we have. Horace, Vieta, Vossius, and Scaliger, have likewise published *Poetics* in Latin; the duke of Buckingham in English; and Menardiere, Hedelin, and Despreaux, in French.

POETRY, *poesis*, the art of composing poems, or pieces in verse.

The word is formed from the Greek ποιέω, of ποιῶ, *facio, I make.*

If a verse be considered as a mere series of just six feet following one after another in the same line, *poetry* and versification will appear two very different things; but Rossu, in his idea of verse, includes cadence, peculiar constructions, arrangements, and expressions, unknown in common discourse; and, above all, a certain noble, bold, elevated, and metaphorical turn and manner of diction. These, he observes, are so essential to *poetry*, that without them the most exact arrangement of long and short syllables makes little else but a kind of measured prose; whereas these, in a discourse that has no poetical feet or measures, do yet give it the poetical character, and make it a kind of *unmeasured poetry.*

The rules of *poetry* and versifying are taught by art, and acquired by study; but this force and elevation of thought, which Horace calls *something divine*, and which alone makes the *poetry* of any value, must be derived from nature; or, according to Aristotle, from some happy transports, to which that author gives the name of madness: ἔστιν ἡ ποίησις οὐκ ἀνδρὸς σοφοῦ, ἀλλ' ἐνθουσιαστικοῦ. But there must be conceived a just solid judgment, to direct and govern this fury of the poet's imagination.

Hence the critic concludes, that *the end* of *poetry* is to please; *its cause*, either the excellence of the poet's genius, or a poetical fury, and transport of the soul, manageable by the judgment; *its matter*, long and short syllables, and feet composed hereof, with words furnished by grammar; and *its form*, the arrangement of all these things in just and agreeable verse, expressing the thoughts and sentiments of the author after the manner already mentioned.

But, after all, how narrow are these bounds, if we consider *poetry* in the light wherein the works of Homer and Virgil leave it? What is here laid down pretends to no praise, which a mere translator may not rise to, and which the war of Catiline might not merit, if turned out of the prose of Sallust. It is with reason, therefore, that we distinguish the *low* and *simple*, from the *greater poetry*; by giving the former the title of *versification*; and that we make *poetry* and *versification* two distinct arts: in effect, there is not more difference between grammar and rhetoric, than between the art of making verses, and that of inventing poems.

The *greater poetry*, then, consists principally in fiction, or the invention of fables; in the expressing of things by allegories and metaphors; and in the inventing of actions, under which the truths which the poet has to teach may be agreeably disguised.

In this view, scarce any poems retain the nature and essence of the grand *poetry*, but the *epopæa*, *tragedy*, and comedy; the rest, be they elegies, satires, songs, or what they will, come under the name of *versification*.

The ancient eloquence, it is observed, was full of mysteries and allegories. The truth was by them usually disguised under those ingenious inventions, called μῦθοι, *fables*, q. d. *words*; as if there were as much difference between these fabulous discourses of the learned, and the common language, as between the speech peculiar to man and the voice of brutes.

At first fables were chiefly used in treating of the divine nature, after the manner they then conceived of it: this occasioned the first poets to be called *divines*, and *poetry* the *language of the gods.* The divine attributes they separated into a number of persons; because the weakness of the human mind could not conceive so much power, and so much action, in a simplicity so strict and indivisible as that of God.

Nor could they speak of the operation of this almighty cause, without speaking likewise of its effect. They therefore added physics to their theology, handling both after the same manner, without quitting their veils or allegories.

Now man being the most considerable of all the works of the Deity, and there being nothing so proper for poets, or of such general use to mankind as such a subject, they therefore added ethics to the former, and treated the doctrine of manners in the same way as they had done divinity and physiology: and hence arose the *epopœia*, or epic poem.

The epic poets have done, with regard to morality, just the contrary of what the divine poets did for their theology. As the too great diversity of divine actions and perfections, so little proportionate to our understanding, occasioned the latter to divide the single idea of the simple essence of God into several persons under different names, as Jupiter, Juno, Neptune, &c. so, on the contrary, the nature of moral philosophy, which never gives any rules for particular things, occasioned the epic poets to unite in one single idea, in the same person, and even in a single action, whatever of the like kind occurs in different persons, and different actions.

Thus, says Aristotle, *poetry* teaches moral philosophy, not by reciting historically what Alcibiades has done or suffered, but proposing what such a person, whom the poet calls by any name he pleases, would necessarily or probably have done or said on the like occasion. It is in this manner that *poetry* represents either the unhappy consequences of designs ill concerted, of wicked actions, &c. or the reward of good actions, and pleasure reaped from a design laid in virtue, and conducted by prudence.

Thus, according to our critic, the poetical actions and persons are all feigned, allegorical, and universal, not historical and singular. This is likewise the sentiment of Horace; who adds, that poets reach morality as well as philosophy; but the preference herein he gives to Homer. This advantage of the poets over mere philosophers arises hence, that all *poetry* is an imitation. Now imitation is a thing extremely natural; and hence this manner of proposing things becomes better fitted to engage the auditors. Again, imitation is an instruction given by examples; and examples are the more proper to persuade, because they prove the thing possible. In effect, imitation is so much the nature of *poetry*, that, Aristotle tells us, it is to this the art owes its rise.

But the poets, by becoming philosophers, did not cease to be divines; on the contrary, the morality they taught, obliged them frequently to introduce the Deity in their works; and the share he had in each action, obliged the poet to make it grand, important, and conducted by the persons of kings and princes.

Add to this, that it likewise obliged the poet to think and speak after a manner elevated above the common pitch of men, and to use phrases equal, in some measure, to the divine persons he introduced; and to this purpose served the poetical, figurative language, and the majesty of heroic verse.

To convey their truths to the best advantage, and adapt them to the particular purposes they were intended for, poets found out various forms. Hence the epopœia and drama.

Epic *poetry* is more for the habits and manners than the passions; these fall rise all at once, and their violence is but of a short duration; but the habitudes are cooler and more gentle, and rise and fall more slowly.

The epic action, therefore, could not be restrained to a day or two, as that of the drama; a longer and a fuller space was required for this than for tragedy, which is

only

only for the paſſions. And hence aroſe a ſtill greater difference between tragedy and the epopœia.

For the tragic violence required a ſtronger and more lively repreſentation than the epic; and accordingly it conſiſts wholly in the action, the poet never ſpeaking, as he does in the epopœia, where there are no actors.

POETRY, *the laws of epic and dramatic*, ſee under EPIC, CHARACTER, INVOCATION, DRAMATIC, THEATRE, TRAGEDY, COMEDY, ACT, SCENE, and SENTIMENT.

For the lower ſorts of POETRY, ſee ODE, SONG, EPIGRAM, ELEGY, SATIRE, &c.

For the hiſtory of Engliſh *poets*, we refer the reader to Mr. Warton's learned, comprehenſive, and accurate work on this ſubject.

POET's *caſſia*, or *poet's roſemary*, in *Botany*, *aforis*, a genus of the *decacia decandria* claſs. Its characters are theſe: it is male and female in different plants, and the empalement of the flower is of one leaf, which is divided into three acute ſegments; the flower has no petals, but thoſe on the male plants have three ſhort ſtamina; the female have a germen, which changes to a globular berry, having a ſingle ſeed. There is but one ſpecies, a native of the ſouthern parts of Europe.

The whole plant being aſtringent, it is likely to be of efficacy in fluxes of the belly, and other diſorders of that kind. Ray.

POGGE, the *cataphractus cottus* of Linnæus, in *Ichthyology*, the name of a ſmall ſea-fiſh very common on moſt of the Britiſh coaſts, and ſeldom more than five inches and a half in length; the head is large, bony, and very rugged; the end of the noſe is armed with four ſharp upright ſpines; on the throat are a number of ſhort white beards; the teeth are very ſmall, ſituated in the jaws; the body is octagonal, and covered with a number of ſtrong bony cruſts, divided into ſeveral compartments; the ends of which project into a ſharp point, and form ſeveral echinated lines along the back and ſides, from the head to the tail; the firſt dorſal fin conſiſts of ſix ſpiny rays; the ſecond is placed juſt behind the firſt, and conſiſts of ſeven ſoft rays; the pectoral fins are broad and rounded, and are compoſed of fifteen rays. See *Tab.* IV. *of Fiſh*, N° 37.

There is an American *cataphractus*, much reſembling this, but having three angles on the hinder part of its head, one on each ſide, and the third in the middle; and its upper chap ſlightly, and its mouth a little prominent; its head is covered with a brown and bony helmet; and its back, ſides, and tail, with ſcales of the ſame colour, engraven with ſmall parallel lines, and of a rhomboidal figure; its belly is covered with a thin limber ſkin.

POGO, a name by which the inhabitants of the Philippine iſlands call their *quail*: it is very like our common quail, but ſmaller.

POINCIANA, in *Botany*. See BARBADOES *flower-fence*.

POINSON, in the *Manege*, is a little point or piece of ſharp-pointed iron, fixed in a wooden handle, which the cavalier holds in his right-hand when he means to prick a leaping horſe in the croupe, or beyond the end of the ſaddle, in order to make him yerk out behind.

POINT, derived from *punctum*, which is formed from *pungere*, *to prick*, is a term in various *arts*.

POINTS, *in Engliſh Antiquity*, were a neceſſary article in the dreſs, at leaſt of men; and mention of them frequently occurs in the antient comedies and other old books.

They were pieces of ſtring about eight inches in length, conſiſting of three ſtrands of cotton yarn, of various colours twiſted together, and tagged at both ends with bits of tin-plate: their uſe was to tie together the garments worn on different parts of the body; particularly the breeches or hoſe, as they were called: hence the phraſe, *to untruſs a point*. With the leathern doublet or jerkin, buttons were introduced, which in time rendered *points* uſeleſs. Theſe points continued to be given on Aſcenſion-day to boys that perambulated the pariſhes, together with willow wands, as a kind of honorary rewards, though diſtinguiſhed only by the name of tags, and become uſeleſs.

POINT, in *Architecture*, *Arches of the third point*, and *arches of the fourth point*. See ARCHES.

POINT, *gauge*. See GAUGE.

POINT, in *Aſtronomy*, is a term applied to certain parts or places marked in the heavens, and diſtinguiſhed by proper epithets.

The four grand *points* or diviſions of the horizon, viz. the *eaſt*, *weſt*, *north*, and *ſouth*, are called the *cardinal points*. See CARDINAL: ſee alſo EAST, WEST, &c.

The zenith and nadir are the *vertical points*.

The *points* wherein the orbits of the planets cut the plane of the ecliptic, are called the *nodes*.

The *points* wherein the equator and ecliptic interſect, are called the *equinoctial points*. Particularly that, whence the ſun aſcends towards the north pole, is called the *vernal point*.

And that, by which he deſcends to the ſouth pole, the *autumnal point*.

The *points* of the ecliptic, where the ſun's aſcent above the equator, and deſcent below it, terminate, are called the *ſolſtitial points*. Particularly the former of them the *ſolſtitial* or *ſummer point*; the latter, the *brumal* or *winter point*.

POINTS, in *Electricity*, are thoſe acute terminations of bodies which facilitate the paſſage of the electrical fluid *from* or *to* ſuch bodies.

Mr. Jallabert was, probably, the firſt perſon who obſerved that a body, pointed at one end and round at the other, produced different appearances upon the ſame body, according as the pointed or round end was preſented to it. But Dr. Franklin firſt obſerved and evinced the entire effect of pointed bodies, both in drawing and throwing off electricity at greater diſtances than other bodies could do it; though he candidly acknowledges, that the power of points to throw off the electric fire was communicated to him by his friend Mr. Thomas Hopkinſon. Dr. Franklin electrified an iron ſhot, three or four inches in diameter, and obſerved, that it would not attract a thread, when the point of a needle, communicating with the earth, was preſented to it; but he found it impoſſible to electrify an iron ſhot, when a ſharp needle lay upon it. He alſo obſerved, that a piece of leaf gold, ſuſpended between two plates (ſee *Experiments in* ELECTRICITY, *Exp.* 7.) always removed farther from that plate to which its ſharpened point was preſented; and that, if one of the *points* was very blunt and the other very ſharp, it would be ſuſpended in the air by its blunt end, though no electrified plate was held below it.

This remarkable property, poſſeſſed by pointed bodies, of gradually and ſilently receiving or throwing off the electric fluid has been evinced by a variety of familiar experiments. Thus, if one hand be applied to the outſide coating of a large jar fully charged, and the point of a needle, held in the other, be directed towards the knob of the jar, and moved gradually near it, till the point of the needle touches the knob or ball, the jar will be entirely diſcharged, ſo as to give no ſhock at all, or a ſhock ſcarce ſenſible.

In this caſe the point of the needle has gradually and ſilently drawn away the ſuper-abundant electricity from the electrified jar.

Farther, if the knob of a braſs rod be held at ſuch a diſtance from the prime conductor, that ſparks may eaſily eſcape from the latter to the former whilſt the machine is in motion; and when this is the caſe, if the point of a needle be preſented, though at twice the diſtance of the rod from the conductor, no more ſparks will be ſeen paſſing to the rod: when the needle is removed, the ſparks will be ſeen, but upon preſenting it again they will diſappear, ſo that the point of the needle draws off ſilently almoſt all the fluid, which is thrown by the cylinder or globe of the machine upon the prime conductor. This experiment may be varied, by fixing the needle upon the prime conductor with the point upward; and then, though the knob of a diſcharging rod or the knuckle of the finger be brought very near the prime conductor, and the excitation be very ſtrong, no ſpark will be perceived, or if there be any, it will be exceedingly ſmall.

The influence of *points* is alſo evinced in the amuſing experiment, commonly called the electrical horſe-race. See *Experiments in* ELECTRICITY, *Exp.* 12.

Again, if a ſmall lock of cotton be ſuſpended from the prime conductor by a thread and electrified, its filaments will repel one another, and extend themſelves towards the neareſt conductor; but if the finger or the knob of a rod be preſented to it, it will move toward the finger or knob, and endeavour to touch it: at the ſame time let a pointed needle be preſented with the other hand to the cotton a little above the end of the finger, and it will ſhrink upwards and move towards the prime conductor; but upon removing the needle, the cotton will return towards the finger; on preſenting the needle again, it will ſhrink; and hence it is inferred, that the point of the needle draws off the electric fluid from the cotton, ſo that it is capable of being attracted by the prime conductor, an effect which the finger or blunt end of the wire could not produce. See THUNDER-*houſe*.

The late Mr. Heely exhibited the efficacy of pointed bodies by ſuſpending a large bladder, well blown and covered with gold, ſilver, or braſs leaf, by means of gum water, at the end of a ſilken thread ſix or ſeven feet long, hanging from the ceiling of a room, and electriſying the bladder by giving it a ſtrong ſpark with the knob of a charged bottle: he then preſented to it the knob of a wire, which cauſed the bladder to move towards the knob, and when nearly in contact to give it a ſpark, and thus to diſcharge its electricity. By giving the bladder another

ſpark, and preſenting to it the point of a needle, the bladder was not attracted by the point but rather receded from it, eſpecially if the needle was ſuddenly preſented towards it. But experiments evincing the efficacy of pointed bodies for ſilently receiving or throwing off the electric fluid, may be infinitely diverſified according to the fancy or convenience of the electrician; and in a work of this kind it is needleſs to enumerate them.

In connection with this ſubject it may be proper to remember, that, in caſe of *points* throwing off or receiving electricity, a current of air is ſenſible at an electrified point, which is always in the direction of a point, whether the electricity be poſitive or negative. This fact has been ſufficiently aſcertained by many electricians, and particularly by Dr. Prieſtley and ſig. Beccaria: the explication of it will be ſubjoined in the ſequel of this article.

Dr. Prieſtley contrived to exhibit the influence of this current on the flame of a candle, preſented to a pointed wire, electrified negatively as well as poſitively. The blaſt was ſo ſtrong (and in both caſes alike) as to lay bare the greateſt part of the wick, the flame being driven from the point; and the effect was the ſame, whether the electric fluid iſſued out of the point or entered into it. He diverſified this experiment in a variety of ways, by placing the flame between two *points*, variouſly circumſtanced in their connection with the prime conductor, electrified poſitively and the floor; with the rubber and the floor; with the rubber and the conductor, &c. He alſo tried the force of this current upon paper vanes, ſtuck into the ſides of a cork, which by means of a needle was ſuſpended on a magnet: theſe vanes he held two or three inches from the point of a wire, communicating with the outſide coating of a jar placed upon an electrical ſtand, and he obſerved, that whenever he took a ſpark from the wire communicating with the inſide, the vanes were ſtrongly blown upon and made to turn, as if the current of air had flowed from the point; in which caſe, according to Dr. Franklin's theory, the electric fluid was entering it. If they were made to turn the contrary way, the current ſoon ſtopped them, and never failed to bring them back and make them move as before. This experiment was varied, and vanes were prepared of thin pieces of braſs, which are conductors, and the effect was ſimilar to that of the former. Dr. Prieſtley alſo found, as Mr. Wilſon had before obſerved, that the vanes would not turn in vacuo, nor in a cloſe unexhauſted receiver where the air had no free circulation. In much the ſame manner, Beccaria exhibited to ſenſe the influence of the wind or current of air driven from *points*. See *Exp.* 11. under *Experiments in* ELECTRICITY.

POINTS, *theory of*. Dr. Franklin endeavoured to account for the efficacy of *points*, by ſuppoſing that the baſe on which the electric fluid at the point of an electrified body reſted being ſmall, the attraction by which the fluid was held to the body was ſlight; and that, for the ſame reaſon, the reſiſtance to the entrance of the fluid was proportionably weaker in that place than where the ſurface was flat: but he was not ſatisfied with this hypotheſis. The facility with which pointed bodies receive or diſcharge the electric fluid may, perhaps, be more ſatisfactorily explained by conſidering, that the electric fluid ſuper-induced upon an inſulated body, is confined upon that body by the ſurrounding air, and that electricity, by being continually communicated to the air, which is never a perfect electric, is gradually diſſipated: whence it follows, that as a greater or leſs quantity of air is contiguous to a given quantity of electrified ſurface, that ſurface will loſe its electricity more ſuddenly or more ſlowly. Thus, as the point of a needle, ſuppoſed to be connected with an electrified prime conductor, is ſurrounded by the air, the electricity will be diſſipated more eaſily from that than from any other part of the prime conductor of the ſame dimenſions, but expoſed to a leſs quantity of air. Beſides, the air about the point may be more eaſily moved in conſequence of the electrical repulſion than at any other part of the ſurface of the prime conductor; and new air, i. e. unelectrified air paſſes more frequently by it, which taking always part of the electricity of that body, further promotes its diſſipation. When the pointed body is negatively electrified, it acquires the electric fluid through the point more eaſily than through any other part of its ſurface; becauſe the point preſenting the leaſt ſurface to the greateſt quantity of air receives a proportionably greater quantity of the electric fluid.

Lord Mahon, in his Principles of Electricity, 1779. explains the influence of *points* in a different manner: he firſt premiſes, that electric atmoſpheres are conſtituted of the particles of air ſurrounding the electrified body: if, e. g. the body be poſitively electrified, he maintains that it will depoſit, upon all the particles of air that ſurround it, and come ſucceſſively in contact with it, a proportional part of its ſuperabundant electricity; ſo that they will become likewiſe poſitively electrified, and form a poſitively electrified atmoſphere. The ſame reaſoning is applied, *mutatis mutandis*, to negatively electrified bodies, and their negative atmoſpheres.

From this principle, and the obſervation that the denſity of an electrical atmoſphere diminiſhes, in a certain ratio, as the diſtance from the electrified body increaſes, as well as from other conſiderations, his lordſhip undertakes to aſſign the cauſe why an electrified body, to which a projecting point is fixed, parts with or receives electricity more readily than a ſmooth cylinder or globular body: becauſe the ſuperabundant electricity of the body, ſuppoſing it to be poſitively electrified, which, in all caſes, tends to quit it, will, when a point is fixed to it, meet with leſs reſiſtance to its eſcape; as the point projects beyond the denſe part of the electrical atmoſphere of the body into the rarer, and, conſequently, more unreſiſting part of that atmoſphere. But the eſcape of the electric matter from any part of a ſmooth cylindrical body, poſitively electrified, is prevented or impeded; becauſe every part of its ſurface is in contact with the denſeſt part of its own ſtrongly reſiſting electric atmoſphere. The ſurface too of the point being extremely ſmall, the leſs will be the reſiſtance oppoſed to the eſcape of the ſuperabundant electricity of the body into that rare part of its electrical atmoſphere into which the point projects. Beſides other illuſtrations of this principle he produces the inſtance of a pointed wire, placed between two round or prominent metallic bodies, with its point on a level with their ſurface. In this ſituation, when preſented to an electrified body, it acts no longer as a point, or only in a very ſmall degree; becauſe the denſe part of the electrical atmoſphere of the two round bodies flows or is extended over it.

As for the current of air iſſuing from the *points* of bodies electrified *plus* or *minus*, Dr. Prieſtley obſerves, that it is not more difficult to be accounted for on Dr. Franklin's hypotheſis of poſitive and negative electricity, than any other caſe of electrical repulſion. The particles of the atmoſphere, near the *points* of electrified bodies, having, by their means become poſſeſſed of more or leſs than their natural ſhare of the electric fluid, muſt retire to places where they can diſcharge or repleniſh themſelves as occaſion may require. If it be aſked why the particles of the atmoſphere do not, in the ſame manner, recede from all the parts of the electrified body, as well as from the *points*; it is anſwered, that as the preſſure of the atmoſphere will prevent a vacuum, and as electrical attraction and repulſion are moſt powerful at the *points* of bodies, on account of the eaſier entrance or exit of the fluid at the *points* (upon whatever principle that effect depends) the electrified atmoſphere, whether negative or poſitive, muſt fly off at the *points* preferably to any other places, and the weight of the atmoſphere will force the air of the neighbouring places upon the flatter parts of the electrified conductor, notwithſtanding the real endeavour it may have to recede from it. Hiſt. of Elect. vol. ii. p. 191, 8vo. edit. 1775.

Beccaria accounts for this phenomenon by obſerving, that *points*, annexed to electrified bodies or preſented to them, throw into the contiguous air, or draw from it the electrified fire with ſuch a force, that in both caſes they repel from themſelves the air, either loaded with part of the fire with which they ſuperabound, or deprived of its own fire, if theſe bodies were themſelves in a ſtate of negative electricity: and theſe *points*, while they drive away the air next to them, throw into or draw from the air, which laterally ſucceeds the electrical fire; and they do this in ſuch a divided manner, that little light or noiſe is produced, but with ſuch rapidity, that a great quantity of fire is really diſcharged in a ſmall ſpace of time. He accordingly diſtinguiſhes between that tickling ſenſation, which the electrical fire excites in us, when the face or hand is immerſed into the atmoſphere of an electrified body, and the current of air above mentioned. The exceſſive fire, he ſays, which actuates this atmoſphere drives the natural fire from the contiguous air to the face, &c. and this fire in paſſing into the ſkin, produces the ſenſation of tickling: but if the body near which we ſtand be negatively electrified, the fire within the ſkin flows to the external ſurface of it, and thus the ſame kind of feeling is produced, whether the fire iſſues out of the body or paſſes into it. But the electric wind is a real current of air, driven from a point either annexed or preſented to a body ſtrongly electrified, and with ſuch rapidity, that the direction of it cannot be diſcerned either with the naked eye or with the aſſiſtance of any glaſs. Artificial Electricity, 1776, p. 332, &c.

POINTS, *application of the doctrine of*. There is not a more important fact in the hiſtory of electricity than the uſe to which the diſcovery of the efficacy of pointed bodies was applied.

Dr. Franklin, having aſcertained the ſameneſs of electri-

city and lightning, was immediately led to propose a cheap and eafy method of fecuring buildings from the damage of lightning, by fixing a pointed metalline rod higher than any part of the building, and communicating with the ground or with the neareft water. See *Pointed Metallic* CONDUCTORS.

This contrivance was actually executed in a variety of cafes, and has proved an excellent preferrative: fome few inftances, however, having occurred, in which buildings provided with fuch conductors have been ftruck and damaged, a controverfy has arifen with regard to their expedience and utility. In this controverfy Mr. Wilfon has taken the lead, and with him Dr. Mufgrave and fome few other electricians have concurred in their oppofition to elevated and pointed conductors. They allledge, that every point, as fuch, follicits the lightning, and thus contributes not only to increafe the quantity of every actual difcharge, but alfo frequently to occafion a difcharge where it might not otherwife have happened: whereas, they fay, if inftead of pointed conductors, thofe with blunted terminations were ufed, they would as effectually anfwer the purpofe of conveying away the lightning fafely, without the fame tendency to increafe or invite it. Accordingly, Mr. Wilfon, in a letter to the Marquis of Rockingham (Phil. Tranf. vol. lix. art. 44.) expreffes his opinion, that, in order to prevent lightning from doing mifchief to high buildings, large magazines, &c. the feveral buildings fhould remain as they are at the top, that is, without having any metal above them, either pointed or not, by way of a conductor; but that on the infide of the higheft part of fuch a building, and within a foot or two of the top, it may be proper to fix a rounded bar of metal, and to continue it down along the fide of the wall to any kind of moifture in the ground.

On the other hand it is urged by the advocates for pointed conductors, that *points*, inftead of increafing an actual difcharge, prevent a difcharge where it would otherwife happen, and that blunted conductors tend to invite the clouds charged with lightning. And it feems to be a certain fact, that though a fharp point will draw off a charge of electricity filently at a much greater diftance than a knob, yet a knob will be ftruck with a full explofion or fhock, the charge being the fame in both cafes, at a greater diftance than a fharp point.

The efficacy of pointed bodies for preventing a ftroke of lightning is ingeniouffy explained by Dr. Franklin in the following manner: an eye, he fays, fo fituated as to view horizontally the underfide of a thunder-cloud, will fee it very ragged, with a number of feparate fragments or fmall clouds one under another; the loweft fometimes not far from the earth. Thefe, as fo many ftepping-ftones, aflift in conducting a ftroke between a cloud and a building. To reprefent thefe by an experiment, he directs us to take two or three locks of fine loofe cotton, and connect one of them with the prime conductor by a fine thread of two inches, another to that, and a third to the fecond, by like threads, which may be fpun out of the fame cotton. He then bids us to turn the globe, and fays we ftall fee thefe locks extending themfelves towards the table, as the lower fmall clouds do towards the earth, but that, on preferting a fharp point, erect under the loweft, it will fhrink up to the fecond, the fecond up to the firft, and all together to the prime conductor, where they will continue as long as the point continues under them. May not, he adds, in like manner, the fmall electrified clouds, whofe equilibrium with the earth is foon reftored by the point, rife up to the main body, and by that means occafion fo large a vacancy, as that the grand cloud cannot ftrike in that place. Letters, p. 121, &c. Mr. Henly, with a view of determining the queftion, whether *points* or knobs are to be preferred for the terminations of conductors made feveral experiments, two or three of which it may not be improper to recite. Having placed two of Mr. Canton's ELECTROMETERS, A and B, (*Tab.* V. *Electricity, fig.* 35.) infulated, upon ftands of fealing wax about feven inches afunder, and at far from the end of a prime conductor, eighteen inches long, and 1¼ inch in diameter, with a ball at each end, 2¼ inches in diameter, the diameter of the electrical globe being nine inches; on the top of the box A, he placed a wire, projecting three inches from the end of it, and terminated by a ball ¾ of an inch in diameter: on the top of the box B, he placed a fharp-pointed wire, projecting alfo three inches from its end. After giving the winch five or fix turns, the balls hanging from the box A, were repelled to the diftance of one inch from each other, but thofe hanging from the box B, feparated full two inches. Then touching the prime conductor with a finger, the balls at A clofed, while thofe at B remained a full inch afunder: hence he infers, that a fharp point is much better adapted to draw off lightning than a knob of ¾ of an inch in diameter.

In another experiment, he infulated three of his largeft jars, containing together about fixteen fquare feet of coated furface; from the bottom of thefe jars projected a wire terminated in a ball ¾ of an inch in diameter; and at the diftance of 1¾ inch from it, he placed the infulated ball C (*fig.* 36.) on which he brought down the charge of the three jars by his difcharging rod, which leaped from thence to the ball in contact with the jars, and difcharged them by a loud and full explofion: but the fame thing did not happen when he removed the infulated ball only one-eighth of an inch farther from the other. He then removed the wire which was terminated by the ball, and placed in its ftead another of the fame length and diameter, but very nicely tapered to a point; then placing the infulated ball C one inch from the point, he brought down the charge of the three jars as before, which flew upon the point and melted it a little; the jars were difcharged with a loud and full explofion. But having removed the ball C to the diftance of 1¾ inch from the point, the charge did not ftrike it, though much of it was prefently drawn off filently by the point, as appeared by the falling of the index of the electrometer. Whence it feems probable, that a conductor terminated by a ball of three-fourths of an inch in diameter, would be in danger of a ftroke from a highly electrified cloud, at a much greater diftance than another with a fharp termination. He alfo varied this experiment by placing the large copper ball C, at fuch a diftance from that in contact with the jar, that on bringing down the charge by his difcharging rod, it feemed to remain almoft undiminifhed, though the rod was kept in contact with the prime conductor a full minute. Then, repeating the experiment with a point inftead of a knob, the charge was in a great meafure prefently drawn off filently.

In another experiment, he fufpended a large bullock's bladder gilded with leaf copper by a filken ftring, at one end of an arm of wood, placed horizontally, and turning freely upon the point of a needle; the bladder was balanced by a leaden weight, (*fig.* 37.) In this fituation he gave the bladder a ftrong fpark from the knob of a charged bottle, when, preferting towards it a brafs rod, terminated by a ball, two inches in diameter, he obferved that the bladder would come towards it at the diftance of three inches; and when it had got within one inch of it, it would throw off its electricity in a full and ftrong fpark, nearly, if not quite as large as that which it had received. But giving it another ftrong fpark, and preferting towards it a pointed wire, he could never perceive that it attended to that, and when it was brought nearly into contact with the bladder, there was no fpark at all, fcarce any fenfible quantity of electricity remaining in it. This experiment was frequently repeated with the fame refult. Phil. Tranf. vol. lxiv. part. ii. art. 18. See THUNDER-*Houfe*.

It has been univerfally allowed, that in cafes where the quantity of electricity with which thunder-clouds are charged is fmall, or when they move flowly in their paffage to and over a building, pointed conductors, which draw off the electrical fluid filently, within the diftance at which rounded ends will explode, will gradually exhauft them, and thus contribute to prevent a ftroke and preferve the buildings to which they are annexed.

But it has been faid by thofe that are averfe to the ufe of fuch conductors, that if clouds of great extent and highly electrified, fhould be driven with great velocity directly over them, or if a cloud hanging directly over buildings to which they are annexed, fuddenly receives a charge by explofion from another cloud at a diftance, fo as to enable it inftantly to ftrike into the earth, thefe pointed conductors muft take the explofion; on account of their fuperior readinefs to admit electricity at a much greater diftance than thofe that are blunted, and in proportion to the difference of that ftriking diftance, do mifchief inftead of good: and, therefore, they add, that conductors terminated by fharp *points* are fometimes advantageous, and at other times prejudicial; and that, as the purpofe for which conductors are fixed upon buildings is not to protect them from one particular fort of clouds only, but if poffible, from all, it cannot be advifeable to ufe that kind of conductors, which, if they diminifh danger on the one hand, will increafe it on the other. Befides, it is pleaded, that if fharp-pointed conductors are attended with any the fmalleft degree of danger, that danger muft be conliderably augmented by carrying them high up into the air, by fixing them upon every angle of a building, and making them project in every direction. Such is the reafoning of Dr. Mufgrave, for which we muft refer to his paper in the Phil. Tranf. vol. lxviii. part ii. art. 36.

Mr. Wilfon, diffenting from the report of a committee of the Royal Society, appointed to infpect the damage done by lightning to the houfe of the board of ordnance, at Purfleet, in 1777, was led to juftify his diffent, and

to disparage the use of pointed and elevated conductors, by constructing a magnificent apparatus, with which he might produce effects similar to those that had happened in the case referred to the consideration and decision of the committee.

With this view he prepared a model of the board-house at Purfleet, resembling it as nearly as poſſible in every eſſential appendage, and furniſhed with conductors of different lengths and terminations. As no apparatus ſufficiently large for repreſenting a thunder-cloud, could conveniently be put in motion, he contrived to accompliſh the ſame end by moving the model of the building, with a velocity anſwering to that of the cloud, which he ſtates, at a moderate computation, to be about four or five miles an hour. In order to conſtruct a proper ſubſtitute for the cloud, he joined together the beſt rims of one hundred and twenty drums, making the ſurfaces formed by the ſeveral junctures even with cloth paſted down, and covering them with tin-foil. Theſe drums formed a cylinder above one hundred and fifty-five feet in length, and above ſixteen inches in diameter. The whole cylinder was made in four ſeparate parts, three of which could eaſily be made to communicate or not with each other; the fourth conſiſting of eight braſs drums, was reſerved for a different purpoſe. The great cylinder, conſiſting of the three parts, and containing five hundred and ninety-two ſquare feet, was ſuſpended about five or ſix feet from the floor by ſilk lines, one end of it hanging over the middle of the long frame on which the model was propoſed to move, and the other being joined occaſionally to the end of a wire four thouſand eight hundred feet long, that was ſuſpended through the whole ſpace of the room; the remote end of this wire hooked on occaſionally to the end of the braſs drums, which made a ſeparate cylinder about ten feet in length, and which was ſuſpended by ſilk lines about ſix feet from the floor, in ſuch a manner that the fartheſt end thereof from the wire was within nine or ten feet from the great cylinder. The long wire with the great cylinder and braſs drums made the whole of the ſubſtitute for a thunder-cloud, when they were properly charged. This apparatus was charged by a machine with one glaſs cylinder, about ten or eleven feet from its neareſt end. The whole of the apparatus was diſpoſed in the great room of the Pantheon; and was applied to uſe in no leſs than fifty different experiments.

It is impoſſible within the limits of this article to do juſtice to Mr. Wilſon's experiments, or to the inferences which he deduces from them. It will be ſufficient to obſerve in general, that moſt of his experiments, in which the model of the houſe, with pointed or blunted conductors annexed to it at the ſame or different heights, and made to move ſwiftly under his large artificial cloud, were intended to ſhew, that conductors with points are ſtruck at a greater diſtance, and with a higher elevation than thoſe with blunt or rounded terminations: and from all his experiments made with pointed and rounded conductors (provided the circumſtances be the ſame in both) he infers, that the rounded ones are much the ſafer of the two; whether the lightning proceeds from one or more clouds; that thoſe are ſtill more ſafe which (inſtead of being, as Dr. Franklin recommends, ten feet high) are very little, if at all, above the higheſt part of the building itſelf; and that this ſafety ariſes from the greater reſiſtance exerted at the larger ſurface. For a farther account of the apparatus, experiments, and reaſoning of Mr. Wilſon, the reader, deſirous of more particular information, is referred to the Phil. Tranſ. vol. lxviii. part i. art. 15.

The committee of the Royal Society, compoſed of nine of the moſt diſtinguiſhed electricians in this kingdom, to whom the conſideration of the moſt effectual method of ſecuring the powder-magazines at Purfleet, againſt the effects of lightning, was referred, expreſs their united opinion, that elevated rods, conſtructed and diſpoſed in the manner which they direct, are preferable to low conductors terminated in rounded ends, knobs, or balls of metal, and that the experiments and reaſons made and alledged to the contrary by Mr. Wilſon, are inconcluſive.

Mr. Nairne, in order to obviate the objections of Mr. Wilſon and others, and to vindicate the preference generally given to elevated and pointed conductors, conſtructed a much more ſimple apparatus than that of Mr. Wilſon, with which he made twenty-ſeven well-deſigned and well-conducted experiments, which ſeem to prove the point as far as it is poſſible to be proved by our artificial electrical apparatus. Of theſe, as the ſubject is of importance, it will be proper to give ſome account. His apparatus and manner are repreſented in *fig.* 38. A is a glaſs cylinder eighteen inches in diameter, B a conductor of wood, covered with tin-foil, ſix feet long, and one foot in diameter, and intended to repreſent a cloud, and D a braſs rod on a ſtand communicating with the earth, to one end of which other rods, terminated with balls of a different ſize or a point might be ſcrewed, and deſigned to repreſent a conductor to a houſe. A braſs ball, four inches in diameter, being ſcrewed on to the end of the rod D, was ſtruck by the ball C, at the end of the charged conductor to the diſtance of ſeventeen inches and four-tenths, and ſometimes to nineteen, and even to twenty inches: a ball, one inch in diameter, received ſtrokes to the diſtance of about two inches, which were ſucceeded by a hiſſing noiſe, and a continued light on the ball, till the diſtance was about ten inches; after which the ſtrokes were renewed and continued to the diſtance of 14½ inches, and occaſionally to 16½ inches: a ball of ½ of an inch diameter, in the ſame circumſtances, was ſtruck to the diſtance of half an inch, and continued luminous till it was removed beyond the ſtriking diſtance as far as thirty-three inches. Inſtead of the ball, a wire about 33 inches long, terminating in a point, was ſubſtituted in its ſtead, but no ſtrokes happened, though the point was almoſt in contact with the ball C; at the diſtance of half a tenth of an inch, the point received a ſtream of fire; beyond that diſtance, it was luminous, and ſo continued whilſt it was gradually removed to the diſtance of ſix feet.

In another experiment, the ball of four inches in diameter, with a hole through it, was uſed; through the hole a wire projected ⅛ of an inch beyond the ſurface of the ball, and directly pointing to the ball C; but neither the ball nor point were ſtruck at any diſtance; the point was luminous at the diſtance of thirty inches: when the point of the wire was made even with the ſurface of the ball, it was ſtruck to the diſtance of 17½ inches. Having ſcrewed a hollow braſs ball 33 inches in diameter, with a hole through it, to a braſs hollow ſtem, and paſſed a wire through it with its pointed end projecting one inch beyond the ſurface of the ball; this apparatus was placed on a ſtand communicating by metal with the earth, at the diſtance of five feet from the conductor or artificial cloud, and directly oppoſite to its ſides; in this caſe the ſtriking diſtance from the ball C to the ball of four inches diameter on the rod D, was 16½ inches: when the point of the wire, paſſing through the ball and ſtem, was made to project nine inches beyond it, the ſtriking diſtance only 6½ inches. In order to diſcover how far a point or differently ſized balls, with ſmall ſeparations in the metallic communication with the earth, would act to carry off the electric fire of the artificial cloud, Mr. Nairne fixed a ſcrew to each end of a ſtick of ſealing-wax, and, having paſted a ſlip of tin-foil over its ſurface, and made a ſeparation of the tin-foil of about ⅛ of an inch, ſcrewed the pointed wire into one end, and the other end of the wax to the braſs rod, where the ball with the point projecting from it was placed in the laſt experiment. The ſtand, being placed directly oppoſite to the ſide of the artificial cloud, was removed to the diſtance at which the light between the ſeparation of the tin-foil no longer became viſible, which was above ſeven feet. When a ball of ⅛ of an inch was put in the place of the point, the light was viſible at the diſtance of four feet ſix inches, but with a ball of three inches diameter, only at two feet. He took another ſtick of wax, 1½ inch in diameter, and about ten inches long, and, having paſted on it round pieces of tin-foil half an inch in diameter, at about half an inch diſtance from each other, ſcrewed one end of it to the receiving rod, *fig.* 39, the pointed wire being ſcrewed into the other end. All the ſeparations of the tin-foil, except two, were connected by a piece of braſs laid on the wax, and the point of the wire was placed nearly in contact with the ball: in theſe circumſtances the fire of the charged conductor ſtruck into the point, and continued to ſtrike till it was gradually removed to the diſtance of 1¼ inch beyond which diſtance it would not ſtrike, but the point continued luminous to the diſtance of three feet. When the connecting braſs piece was removed, the point was not ſtruck till it was removed to the diſtance of 4½ inches; it continued to be ſtruck to the diſtance of ten inches, after which it was not luminous, except when the artificial cloud diſcharged its electric fire into the air, by a diverging pencil from the ball C.

From the experiments above recited, we may infer, that the artificial cloud ſtrikes at diſtances greater, as the termination of the conductor is more blunted; that the ſtriking diſtance is leſs as the end of the conductor tends more to a point; and that when the end of a conductor is pointed, the point is not ſtruck at any diſtance, but continues luminous to a certain diſtance, carrying off ſilently the electricity of the artificial cloud. We may alſo infer the utility of a pointed rod, even if it projects but a ſmall diſtance above the higheſt part of a building; that a point within the ſurface of a ball does not prevent

the ball being ſtruck; that the more elevated our pointed conductors are, the greater is the chance of preſerving buildings from the effects of lightning; that a conductor terminating in a point acts at a much greater diſtance than one terminating with a ball, in carrying off the electric fire; that the reaſon why the artificial cloud ſtrikes to the *point*, is the ſeparation or diſcontinuance of the metallic part of the conductor; that it ſtrikes farther to the *point* as the number of ſeparations is increaſed; and that, if the metallic communication with the moiſt earth be completed, the charged cloud will not ſtrike to the *point*.

Another part of Mr. Nairne's apparatus (ſee *fig.* 40.) is a moveable artificial cloud, conſiſting of a hollow tube of wood, with a ball at each end, about ſix feet in length; from the ends are ſuſpended hollow wooden cylinders E, E, which, together with the balls and tube, are covered with tin-foil; the axis of the tube reſts on two ſemicircular hollows in a piece of braſs fixed on a glaſs pillar I, round which axis it eaſily moves, and is brought to a horizontal poſition by means of two moveable pieces F, F. Having put this moveable cloud into an horizontal poſition, and the braſs on which the axis reſted into contact with the end of the artificial cloud B, under each of the hollow cylinders E, E, Mr. Nairne placed ſtands G, G, having a good metallic communication with the earth, one of which was furniſhed with a pointed wire, and the other with a braſs ball, three inches in diameter. Each of theſe was placed twelve inches from the bottom of its correſponding cylinder; and when the clouds were charged, the point became luminous, and the moveable cloud remained in a horizontal poſition; but when the operation of charging the two clouds was diſcontinued, it was immediately found, that the *point* had drawn off almoſt all the electric fire. When the clouds were again charged, and the ſtand with the ball removed, the *point* was luminous, and the moveable cloud remained horizontal, not being attracted to the *point*, which carried off the electric fire. But when the clouds were charged, the ſtand with the ball reſtored, and that with the pointed wire removed, the end over the ball was attracted down till it came to its ſtriking diſtance, where it diſcharged its electricity on the ball in a ſtrong ſpark. It then receded a little, and being charged, approached the ball as before, and diſcharged its electricity at once, and thus continued ſtriking and receding as long as the two clouds were charged. When the pointed wire was replaced, it became luminous, the ſtriking ceaſed, and the moveable cloud returned to its horizontal poſition. The effect was the ſame, when the pointed wire was placed on the ſame ſide with the ball. The concluſions from theſe experiments are obvious. From other experiments, in which the moveable artificial cloud was made to repreſent a cloud in its natural ſtate receiving electric fire from a charged cloud, it was found, that the *point* deprived it of its electric fire which it received from the charged one ſo faſt, that the artificial cloud could keep conſtantly ſtriking to the other end, without repelling it from it; but that, when the ball was placed in the room of the *point*, inſtead of the artificial cloud continuing to ſtrike to the other end, without repelling that end, it now firſt attracted and charged it with electricity, then immediately repelled it; and being attracted by the ball under the other end, it moved down with an increaſing velocity, till it came within its ſtriking diſtance, when it diſcharged its electricity on the ball with a loud and ſtrong ſpark, and ſo continued alternately receiving and diſcharging its electric fire on the ball, according to the known laws of electricity. In another experiment it was found, that, though the moveable artificial cloud was in great motion, receiving and diſcharging its electric fire on the ball, on taking away the ball, and putting the *point* in its place, the artificial ſtorm immediately ceaſed. When the cloud is fixed at a certain diſtance between the artificial cloud and the *point*, the fixed cloud, at the inſtant it receives the electric ſpark, directly diſcharges it again on the *point*; but without any other alteration, beſides making the cloud moveable on its axis, the diſtances being the ſame, the end of the cloud then recedes from the *point*, and will not ſtrike to it; and this caſe is much more agreeable to nature than the other, becauſe clouds are not fixed but floating bodies.

In order to obſerve the effects of rods terminating with balls of different ſizes, or terminating with a *point*, moving ſwiftly under the artificial cloud, Mr. Nairne made uſe of the apparatus repreſented in *fig.* 41. in which H is a hollow tube of wood, covered with tin-foil, with a heavy weight faſtened to one end of the tube, ſuſpended by an axis, about three inches above the weight, between two wooden pillars: in this wooden tube there was a moveable braſs rod, by means of which a ball, or *point*, fixed on it, might be raiſed to any required height. To the under part of the artificial cloud, at K, was fixed a ball of $\frac{1}{4}$ths of an inch in diameter; and then the apparatus was placed under it with a *point*, the ſwinging rod being held down to the floor, as in *fig.* 42. and the *point* covered; the artificial cloud was then charged, and the ſwinging rod with the *point* being let go, paſſed ſwiftly and very near to the ball under the artificial cloud at K. This was repeated ſeveral times, till the greateſt ſtriking diſtance to the *point* was found, which was generally $1\frac{1}{2}$th of an inch. Inſtead of the *point*, a ball $\frac{1}{4}$ths of an inch in diameter was applied in the ſame manner, and the ſtriking diſtance was generally found to be $2\frac{1}{2}$ inches. When a ball of $1\frac{1}{4}$ths of an inch was uſed, the ſtriking diſtance was generally fifteen inches. Here we may obſerve, that the ſingular diſappearance and re-appearance of the ſparks, on gradually removing the ſmall conductor from the prime conductor, already mentioned, occurred likewiſe in the two firſt of the caſes juſt recited; but when the large ball was uſed, it was ſtruck uninterruptedly till it was removed to the diſtance of ſixteen inches. From theſe laſt experiments it appears, that the *point* is ſtruck by means of a ſwift motion, but that the ball of $\frac{1}{4}$ths of an inch was ſtruck farther than the *point*, and the larger ball at a much greater diſtance than either, even with the ſwifteſt motion. Upon the whole, Mr. Nairne ſeems to be juſtified in preferring elevated pointed conductors; next to them thoſe that are pointed, though they project but a little diſtance above the higheſt part of a building; and after them thoſe terminating in a ball, and placed even with the higheſt part of a building. For a farther account of theſe curious and uſeful experiments, and the author's remarks on thoſe of Mr. Wilſon, the reader is referred to Phil. Tranſ. vol. lxviii. part ii. art. 37.

POINT, in *Geometry*, according to Euclid, is a quantity which has no parts, or which is indiviſible.

Wolfius defines it, that which terminates itſelf on every ſide; or which has no terms or boundaries diſtinct from itſelf.

This is what we otherwiſe call the *mathematical point*, and is only conceived by the imagination; yet it is in this that all magnitude begins and ends, the flux or motion of the *point* generating a line, that of a line a ſurface, &c.

Hence ſome define a *point* to be the inceptive of magnitude.

Hobbes defines a *point* to be a body whoſe magnitude is not conſidered. But his falſe notions of a *point*, line, and ſurface, have led him into many errors. Monſieur de Crouzas alſo has ſuppoſed a line to be compoſed of *points*, in his Geometry and comment on the Analyſe des Infiniment petits. This ſuppoſition only tends to confound learners. See Jo. Bernoulli Oper. vol. iv. p. 161, ſeq.

A line can only cut another line in a *point*. Any three *points* being given out of a right line, a circle, or part of a circle, may be drawn, that ſhall paſs through them all. To *draw a parallel line, a perpendicular, a tangent*, &c. *to a given point*, are popular problems in geometry. See PERPENDICULAR, PARALLEL, TANGENT, &c.

POINT, *conjugate*, in *Geometry*, is uſed for that *point* into which the *conjugate* oval, belonging to ſome kind of curves, vaniſhes. Maclaur. Algebr. p. 308.

POINTS, *proportion of mathematical*. It is a current maxim, that all infinites, whether infinitely great, or infinitely ſmall, are equal; yet is the maxim falſe in both caſes. Dr. Halley ſhews ſeveral infinite quantities, which are in a finite proportion to each other; and ſome infinitely greater than others. See INFINITE *quantities*.

The like the hon. Mr. Roberts ſhews of infinitely ſmall quantities, viz. *mathematical points*.

He demonſtrates, for inſtance, that the *points* of contact between circles and their tangents, are in a ſubduplicate proportion to the diameters of the circles; that the *point* of contact between a ſphere and a plane is infinitely greater than that between a circle and a tangent; and that the *points* of contact in ſpheres of different magnitudes are to each other as the diameters of the ſpheres.

POINT *of contrary flexure*, in the *Higher Geometry*. See *Point of* INFLECTION, and RETROGRADATION *of curves*.

POINT *of reflexion*, in *Geometry*, is commonly uſed inſtead of *point of* RETROGRADATION, or retrogreſſion.

POINT, in *Grammar*, is a character uſed to mark the diviſions of diſcourſe.

The *point proper* is what we otherwiſe call a *full ſtop*, or period, and ſerves to denote the ſenſe complete, and the period ended. See PAUSE.

Two points uſually mark the middle of a period, and ſhew a conſtruction complete, and the ſenſe to be perfect; yet intimating ſomething to come after it: this we call a COLON.

A *point* with a comma, called a SEMICOLON, marks a sense less complete than the colon; though authors seem to use them indifferently; nor are grammarians agreed about their precise difference.

The COMMA, or virgula, marks a subdivision of a member of a period. To these *points* Dr. Ward adds the SEMI-PERIOD.

Besides these primary *points* which distinguish *sentences*, there are others which Dr. Ward calls *notæ affectuum*, and which Dr. Lowth says, denote a different modulation of the voice in correspondence with the sense: such are *A point of interrogation*, ?, which marks something to be pronounced in a higher tone, as intimating a question asked. *A point of admiration, or exclamation* !, which marks a sudden surprise and wondering; and a PARENTHESIS.

The interrogation and exclamation *points* are indeterminate as to their quantity or time, and may be equivalent in that respect to a semicolon, a colon, or a period, as the sense requires. They mark an elevation of the voice.

The parenthesis, which incloses in the body of a sentence a member inserted into it, which is neither necessary to the sense, nor at all affects the construction, marks a moderate depression of the voice, with a pause greater than a comma.

Our *points* and accents were entirely unknown to the ancients. In the ancient Greek manuscripts, the whole discourse seems written with the same stroke of the pen; the words and letters being joined throughout.

In after-times, *points* were invented, and added at the top of the letters, to shew when the sense was finished. Hence the grammarians, coming to retouch the old manuscripts, thought fit to add the *points* and accents. Salmasius affirms, that he has even observed plainly where they have been added, by the difference of hands. See PUNCTUATION.

POINTS, or *vowel* POINTS, in the *Hebrew Learning*, are certain characters, which, in the writings of that language, serve to mark the vowels.

The antiquity of the *points* in the Hebrew tongue makes the subject of a celebrated controversy among the learned; some maintaining their origin to be the same with that of the Hebrew language; and others affecting them to have been first introduced by Ezra, after the Babylonish captivity, when he compiled the canon, transcribed the books into the present Chaldee character, and restored the purity of the Hebrew text.

Others will have them invented by the doctors of the school of Tiberias, usually called the Masorites, about five hundred years after Christ. The rabbin Elias Levita was the first who started this question, in the beginning of the fifteenth century; and maintained them to have been an invention of the Masorites, for the ease of those who were to learn the Hebrew tongue.

This sentiment was espoused by Capellus, to whom also adhered Luther, Calvin, Calvinson, Scaliger, Masclef, Erpenius, Mercer, Morinus, Drusius, Le Clerc, Walton, Hare, Bentley, Newton, Sharpe, &c. who are all opposers of the antiquity of vowel *points*. To these we might add several of the Jews, particularly Aben Ezra, who lived in the twelfth century; and almost all the learned men of the Romish persuasion. Buxtorf attacked Capellus violently on this article, and gained a great number of divines on his side, who took the alarm, imagining it a grievous wound to the holy text, to allow the vowel *points* to have been added by the Masorites, and not to have been found in the ancient text; because, without these, it is very difficult to fix the certain reading thereof. Yet, in the Samaritan text, there is no *point* or vowel, nor in many of the most ancient Hebrew manuscripts.

Those who maintain that the Hebrew *points* were not invented by the Masorites, alledge, that there is no mention in any Jewish writer of such an alteration, as the introduction of the *points*, being made in the Hebrew Bible; that all the annotations or notes of the Masorites upon the vowels, relate to the irregularity of them, which could not have been occasioned by themselves, but must have existed in the copies that were before them; that express mention of the *points* or vowels occurs in books more ancient than the Talmud, viz. Babir and Zoar, the first said to be written a little before our Saviour's time, and the second about a century later. However, these books are justly rejected by others as spurious. Prideaux says, that many particulars occur in their books, which prove that they must have been written above a thousand years after the pretended time of their composition; and farther it is pleaded, that the *points* were in use in our Saviour's time, from Matt. v. 18. whence it appears, that the tittles or *points* at that time belonged to the law. But Capel understands by the *tittles*, not the *points*, but the cornelie or flourishes made about the Hebrew consonants.

Those who are of opinion that the *points* are coeval with the consonants, argue, that it is impossible to pronounce the language without vowels, and also to teach it, unless the vowels were expressed; that if the vowels are of human and late invention, the authority of the holy Scriptures will be weakened, and the sacred text left to an arbitrary and uncertain reading and interpretation. But to this objection it is replied, that ה, ו, י, and ע, originally served for vowels. Nevertheless, this answer seems insufficient; because there are many words in which these letters do not occur; and it is argued, from the nature and structure of the Hebrew language, and its dialects, in which the radicals or primitive words are formed by triads, compoſed by the conjunction of different consonants or letters, that some other letters muſt neceſſarily belong to the language. However, it is certain, that the matres lectionis, as the above letters are called, have been sometimes omitted; for they are more frequent in some of the older manuscripts than in the later, or in the printed text.

The arguments against the antiquity of the Hebrew *points*, tending to prove that they were added by the Masorites, are deduced from grammar, testimony, and history. The grammatical arguments are principally founded in the Keri and Cheibh. The Keriith, it is agreed, began to be collected a little before the completion of the Talmud, probably by the Masorites; and it is observed, that they are various lections merely of the consonants, and not of the vowel *points*; and that there are certain irregularities in the punctuation, both with respect to whole words, and the parts of words, which shew that the *points* were not in the copies, from whence the Keri and Cheibh were made.

The testimony which furnishes the second class of arguments, is either express or tacit. Of the first sort is the testimony of Aben Ezra, R. David Kimchi, R. Jehuda Levita, and R. Elias Levita, who deny the antiquity of the vowel *points*. The tacit testimony is derived from the copies of the law, which are kept and read in the synagogues, or from the cabalistic interpretation, or from passages of the Talmud. Those copies of the law, called Sepher-torah, read every Sabbath, and reckoned the most sacred, are constantly written without *points*; to which we may add, that in many manuscripts, examined by Dr. Kennicott, and those some of the oldest and best, either there are no *points* at all, or they are evidently a later addition. The cabalistic interpretations relate to the consonants, and none of them to the vowels. When the Talmud was compoſed, the *points* were not affixed to the text, because there are several disputes concerning the sense of the passages of the law, which could not have been disputed, if there had been *points* besides, the vowels are never mentioned, when the fairest opportunity occurred for mentioning them, if they had been in being.

The arguments from history are drawn from the Chaldee paraphrases of Jonathan and Onkelos, the Greek versions of Aquila, Symmachus, and Theodotion, and especially that of the Septuagint; whence it is argued, that the copy from which these were translated was without *points*; as several words are translated in a different sense from that which the *points* would determine them to mean. Those who wish to see a compendious abstract of the arguments for and against the antiquity of *points*, and of the state of this controversy, may consult Jennings's Jewish Antiq. vol. ii. p. 344. &c.

Dr. Prideaux has an hypothesis peculiar to himself: he apprehends that the *points* were added by more ancient Masorites than those of the school of Tiberias, from after Ezra, when the Hebrew ceased to be a living language, but that they were not in common use, nor taught in the theological schools, till after the compilation of the Talmud. Conn. part i. book v. vol. i. p. 5—520. ed. 10.

POINTS, in *Heraldry*, are divisions of the escutcheon into several squares, sometimes to the number of 9, sometimes to 13; some whereof are of one colour or metal, the others of another; called also *equipolent points*.

There is also another, and that more frequent division of the escutcheon into *points*, which have several names and values, according to their several places.

There are nine principal points in an escutcheon, as marked in *Tab. Herald. fig.* 38. and described under ESCUTCHEON.

Columbiere makes the *points*, and their situations, symbolical. As the several bearings in an escutcheon are by many types representing the commendable actions of the person they are given to; so the escutcheon itself represents the body of the man that performed them; and the *points* or parts signified by these letters, the principal parts of his body. Thus, A, B, C, represent the head, in which the three great faculties reside; D, the neck, where ornaments are chiefly borne; E, the heart, &c.

POINT is also the name of an ordinary, something like the pile,

pile, rising frequently from the bottom of the escutcheon to the top, very narrow, and only taking up two-thirds of the *point* of the escutcheon.

When the *point* arises from the base, it is peculiarly called *point-in-point*.

POINT *couverted* is when it descends from the chief downwards; possessing two thirds of the chief, but diminishing as it approaches the *point* of the escutcheon, though without touching it.

POINT *in bend, or point in bar*, is when the *point* is placed transverse, in the situation of a bend or bar.

When it comes from the sides of the escutcheon, it is also called a *point dexter* or *sinister*, according to its situation.

The *point dexter* is commonly reputed an abatement due to a braggadocio. *Point-champain* is due for killing a prisoner after quarter demanded. *Point-in-point*, a diminution belonging to a coward. *Point-plane*, an abatement belonging to a lyar, &c. See DIMINUTION.

POINT is also used in heraldry for the lowest part of the escutcheon, which usually terminates in a *point*.

POINT-*champain*. See CHAMPAIN.

In the French arms, the fleur-de-lys are two in chief, and one in *point*.

POINT, in the *Manege*. A horse is said to make a *point*, when in working upon volts, he does not observe the round regularly, but pulling a little out of his ordinary ground, makes a sort of angle or *point* by his circular tread. This fault is prevented by hastening the hand. See HASTE.

POINT is also used to denote the toes of a row of a saddle.

POINT, in the *Manufactories*, is a general term used for all kinds of laces wrought with the needle.

Such are *point de Venice, point de France, point de Genoa*, &c. which are distinguished by the particular œconomy and arrangement of their *points*.

POINT is sometimes also used for lace woven with bobbins, as *English point, point de Malines, point de Haure*, &c.

POINT is also an iron or steel instrument, used, with some variety, in several arts.

Engravers, etchers, cutters in wood, stone-cutters, &c. use *points* to trace their designs on the copper, wood, stone, &c.

Statuaries, &c. have likewise *points* in manner of little chissels, used in the first forming or sketching out their work.

Turners work or fashion their common works between two *points* fastened to the puppets. Lapidaries have also iron *points*, to the ends whereof are fastened pieces of diamonds, serving to pierce the precious stones.

POINT, in *Music*, is a mark or note anciently used to distinguish the tones.

Hence we still call it simple *counter-point*, when a note of the bass answers precisely to that of the treble; and figurative *counter-point*, when a note is syncopated, and one of the parts makes several inflexions of the voice or tone, while the other only makes one.

We still use a *point* to raise the value of a note, and prolong its time by one half; e gr. a *point*, added to a semibreve, makes it, instead of two minims, equal to three.

POINT, in *Navigation* and *Geography*. *Points of the horizon*, or *of the compass*, are certain *points*, formed by the intersections of the horizon with vertical circles.

The number of these *points*, therefore, is really the same with that of the *points* conceived in the horizon, i. e. infinite; though, in practice, we only distinguish thirty-two of them.

Some use *point* for the intersection of a vertical circle with a circle parallel to the horizon; and even some, for the segment of a vertical, intercepted between the meridian and horizon, or a circle parallel thereto.

The *points* are shewn by right lines drawn from a *point* assumed in a horizontal plane.

A *point of the compass* is popularly taken for a 32d part of the whole; or for an arch of 11 degrees 15 minutes; half of which, viz. 5° 37′ 30″, is called a *half point*; and half of that, or 2° 48′ 45″, a *quarter point*.

These *points of the compass* are divided into CARDINAL and COLLATERAL.

POINT, in *Optics*. The *point* of *concourse*, or *concurrence*, is that, wherein converging rays meet, more usually called the FOCUS.

POINT *of dispersion*. See DISPERSION.

POINT *of incidence*. See INCIDENCE.

POINT *of reflection*. See REFLECTION.

POINT *of refraction*. See REFLECTION.

POINT, *radiant*. See RADIANT.

POINT, in *Perspective*, is a term used for various parts or places, with regard to the perspective plane. Such are the

POINT *of sight, or of the eye*; this is a *point* F on a plane HI (*Tab. Perspect. fig.* 12. N° 1.) marked out by a right line OF, drawn from the eye, perpendicular to the plane. This is also called the *principal point*.

This *point* is in the intersection of the horizontal and vertical planes.

Some authors call this the *principal point*; and give the name *point of sight*, or *vision*, to the *point* wherein the eye is actually placed, and where all the rays terminate; as O. See PERSPECTIVE, and POINT *of view*.

POINT *of distance* is a *point*, v. gr. P or Q, in the horizontal line PQ, at the same distance from the principal *point* F, as the eye O is from the same. See PERSPECTIVE.

POINT, *third*, is a *point* taken at discretion in the line of distance, wherein all the diagonals drawn from the divisions of the geometrical plane concur.

POINT, *objective*, a *point* on a geometrical plane, whose representation is required on the perspective plane.

POINT, *accidental*. See ACCIDENTAL.

POINT, *visual*. See VISUAL.

POINT *of view*, with regard to *Building, Painting*, &c. is a *point* at a certain distance from a building, or other object, wherein the eye has the most advantageous view or prospect of the same.

This *point* is usually at a distance equal to the height of the building. For an instance: to consider with judgment the whole of the famous church of the invalids at Paris, we must not stand at above three hundred and forty feet distance from it, which is nearly its height. To be able to judge of the ordonnance of its façade or frontispiece, and the regularity of its order, the eye should only be as far off as the frontispiece is high; viz. a hundred feet.

But to examine the correctness of its profiles, and the spirit of its ornaments, the eye should only be distant the height of the Dorie order, which is about forty feet; if it be nearer, the parts, being too much shortened, will appear out of proportion.

A vague or indeterminate *point* has a different effect from the *point of view*; in that, in looking at a building from an indeterminate *point*, the eye can only form an idea of the magnitude of its mass, by comparing it with other buildings adjacent to it.

POINT, *punctum*, in *Physics*, is the smallest or least sensible object of sight, marked with a pen, point of a compass, or the like.

This is what we popularly call a *physical point*, which, in reality, has parts, though those parts are not here regarded. Of such *points* does all physical magnitude consist.

This *physical point* coincides with what Mr. Locke calls the *point sensible*, and which he defines to be the least particle of matter, or space, we can discern. He adds, that, to the sharpest eye, this is seldom less than thirty seconds of a circle, whereof the eye is the centre.

POINT, in *Poetry*, denotes a brisk lively turn or conceit, usually found or expected at the turn of an epigram.

POINT, among *Seamen*, is also used for a cape, or headland, jutting out into the sea.

They say, two *points* of land are *one in another*, when they are so in a right line against each other, as that the innermost is hindered from being seen by the outermost.

POINTS are also used to denote short flat pieces of braided cordage, tapering from the middle towards each end, and used to reef the courses and top-sails of a ship.

POINT-BLANK, in *Gunnery*, denotes the shot of a gun levelled horizontally, without either mounting or sinking the muzzle of the piece.

In shooting *point-blank*, the shot or bullet is supposed to go directly forward, in a straight line, to the mark; and not to move in a curve, as bombs and highly elevated random shots do.

When a piece stands upon a level plane, and is laid level, the distance between the piece and the *point* where the shot touches the ground first, is called the *point-blank* range of that piece; but as the same piece ranges more or less, according to a greater or less charge, the *point-blank* range is taken from that of a piece loaded with such a charge as is used commonly in action. It is, therefore, necessary that these ranges of all pieces should be known, since the gunner judges from thence what elevation he is to give to his pieces when he is either farther from or nearer to the object to be fired at; and this he can do pretty nearly by sight, after considerable practice. See *Pointing of a* GUN.

POINTED *arrow*. See CROWN.

POINTED *roof*. See ROOF.

Scots POINTED, among *Heralds*, is that which has the extremities turned off into *points* by strait lines. Columbiere calls it *aiguisé*, q. d. *sharpened*.

POINTERS, in *Ship-Building*, are pillars in an oblique position, from the floor-rider heads on each side, pointing

ing or meeting each other at the middle of the gun-deck beams.

POINTING, *punctuation*, in *Grammar*. See PUNCTUATION.

POINTING, among *Seamen*, the marking on the chart in what point or place the veſſel is.

All the difficulty in *pointing* a chart ariſes from our ignorance of the longitude. The pilot eaſily finds the latitude, by taking the height of the pole; but, for the LONGITUDE, there is no coming at it, but by computation, which is always uncertain.

POINTING is a ſea-term, denoting the operation of tapering the end of a rope, and weaving a ſort of mat or cloſe texture about the diminiſhed part of it, ſo as to thruſt it more eaſily through any hole, and prevent it from being readily unwitted. This operation is applied to the reef-line, and to the cable, for the purpoſe of ſplicing it, and that it may more eaſily paſs, when ſpliced, through the hauſe-holes.

POINTING, in *War*, the levelling or directing a cannon, or mortar-piece, ſo as to play againſt any certain point. See *Pointing of a* GUN, and *Gunner's* QUADRANT.

POISE. See CHANTEPOTTE, WATERPOISE, &c.

POISON, in *Medicine*, a malignant quality in ſome animal, vegetable, or mineral body, which renders it hurtful, and even fatal, to thoſe who take it even in a ſmall quantity.

The word is derived from the Latin *potio*, *draught*; and was anciently uſed in an innocent ſenſe. See POTION.

Some define *poiſon* to be any thing taken inwardly, whoſe properties are contrary to thoſe of food, or to what they ſhould be, in order to nutrition.

However, this vague and uncertain ſenſe of the word introduces great confuſion into the writings of thoſe who thus uſe it.

Poiſons are of various kinds, and operate in various manners; ſome by diſſolving the blood, others by coagulating it, and others by corroding and deſtroying the ſolid parts. Some attack equally all the parts; ſome only a particular one. Thus, the lupus marinus is an enemy to the lungs, canthariſes to the bladder, &c.

Some things, again, which prove *poiſon* to man, ſerve for food to other animals. Thus, mandragora and henbane feed hogs, though they kill man; and thus that deadly *poiſon* hemlock is wholeſome for goats, buſtards, and, as Galen ſays, for ſtarlings too. The caſſavi plant, Sir Hans Sloane tells us, *poiſon* unprepared; but prepared, is the common bread of the Weſt-Indies, particularly in Jamaica, and the better parts; and is uſed to victual ſhips. Nay, what is more, ſome *poiſons* are not only food, but even phyſic to other animals. In the Philoſ. Tranſact. we have an inſtance of a horſe troubled with a farcy, which could not be cured by the moſt famed remedies, which yet cured himſelf in a ſhort time, by feeding greedily on hemlock. Fontanus alſo tells us of a woman, who eat hemlock for ſome time, to procure ſleep, and with very good effect, though repeated doſes of opium had no operation.

Dr. Tane. Robinſon, in a letter to Mr. Ray, gives an account of ſeveral poiſonous plants, which, if truly corrected, or exactly *doſed*, he ſays, may prove the moſt powerful remedies known. Thus the helleborus, incorporated with a ſapo, or with alcali falts alone, are ſucceſsful in epilepſies, vertigoes, palſies, lethargies, and mania: doſe from 9j to 3ß. The roots of cicuta, aſarum, and napellus, in agues, and periodical pains; doſe 3j to 3ß. The hyoſcyamus in hæmorrhages, violent heats, and inflammations; doſe 3j to 3ß. The ſemen ſtramonii is a good anodyne, uſeful in vigilias, rheumatiſms, hyſteric caſes, &c. doſe 9j to 3ß. Elaterium, ſoldanella, and gratiola, are alſo good in hydropic caſes. Opium, corrected, loſes its narcotic quality, and is ſafely given, in great doſes, in convulſive caſes, fluxes, catarrhs, &c.

Poiſons are diſtinguiſhed by ſome authors by ſeveral names, according to the different time and manner of their taking effect.

Some are called *venena terminata*. Theſe are ſuch *poiſons* as perform their fatal office, according to the opinion of the world, at certain ſtated or determinate periods of time; thus, according to the quantity given, or the nature of the ſpecies of *poiſon*, a man muſt be killed by it at the pleaſure of the giver, either in an hour, a day, a week, a month, many months, or years; the *poiſon* in this laſt caſe operating like a chronical diſeaſe, and carrying off the patient by a very tedious train of ſymptoms.

Others are called *venena temporanea*, *temporary poiſons*. Theſe will kill a man by degrees, every minute of his life growing worſe and worſe, from the time of taking them to the final period; but this is not at any ſtated or certain time.

Others are called *deliquaria venena*. Theſe are ſuch as kill without being taken internally, and are rarely fatal if rubbed upon the ſkin, put into gloves, or the like.

As to the firſt of theſe kinds, it is very much to be doubted whether there be in nature any ſuch thing as a *venenum terminatum*, or a *poiſon* which ſhall kill at the fixed time at which the giver pleaſes; ſince all the known *poiſons* are only relatively ſuch, and depend for their effect on the peculiar ſtate of the body: the different conſtitutions of men muſt therefore vary the period of time at which death muſt happen from the taking of the ſame doſe. At leaſt, if it be poſſible to contrive a terminatory *poiſon*, it muſt require the ſkill of the ableſt phyſician to prepare it, ſince he muſt at once know the true ſtate of the perſon's body who is to take it, and the exact power of the *poiſon*, in its ſeveral doſes, on other bodies.

Much, therefore, is required in the phyſician who is to cure a perſon who has ſwallowed *poiſon*; ſince the nature of the medicine, and the true knowledge of the ſtate of the patient's body, are both neceſſary, in order to know what ſymptoms to expect and guard againſt.

Of the number of thoſe *poiſons* which take a long time to kill, and that different, according to their doſe and the habit of the perſon, are the venom of the toad and of the mad dog, whether the ſaliva be communicated immediately to the blood by a wound, or ſwallowed with food or with the ſpittle. The *poiſon* of the tarantula is alſo of this number; and to theſe may be added, that of the ſmall pox, meaſles, and other diſeaſes of that kind, which is evidently long dormant in the body, till certain peculiar occaſions and accidents call it forth to appear in its proper form. The *poiſon* of the hectic fever is alſo by ſome referred to this, it being accounted an alkaline virus, mixed with a viſcid matter. The *poiſon* of the French pox, *lues venerea*, is alſo of this kind, and is eſteemed highly acrid and alkaline. The *poiſons* of cantharides, the acid ones of nitre, ſalt, vitriol, ſulphur; the ſolutions or cryſtals of gold, ſilver, and the other metals; and the precipitates of mercury, and the very fatal common *arſenic*. To theſe are added many others, and among them ſome which act merely mechanically, by their numerous ſharp points and edges; ſuch as the powder of diamonds, glaſs, and the like: and to this claſs belong many of the deliquatory *poiſons*.

Of the temporaneous *poiſons* many are taken under the common denominations of food and drink, and ſeem at firſt to be of no injury; but by degrees they impair the conſtitution, and bring on diſeaſes and death. Coffee, tea, and all the ſpirituous liquors are accounted of this kind.

We may perhaps aſcribe the prodigious multiplicity of *poiſons*, and that equally numerous tribe of antidotes created of by the ancients, to the love of the marvellous: however, it cannot be denied, that ſome things are very ſuddenly and ſtrangely deſtructive to animal life, and that in very ſmall quantities. Among the reſt, there is a *poiſon* made uſe of by the Indians, ſome of which was ſent over to the Royal Society by M. de la Condamine: Dr. Brocklesby has given us ſome accounts of its effects on cats, dogs, and birds, who were ſoon killed by it, only by ſprinkling a few drops of the ſolution of this *poiſon* on wounds made by a lancet. The doctor gave alſo two drachms of ſugar to a bird, and ſhortly afterwards poured a little of the ſolution into its mouth; but two drops had ſcarce touched its tongue, before the creature was convulſed, and could with difficulty be laid down before all motion was taken away.

Hence it appears, that ſugar is no ſpecific againſt this *poiſon*, even when only taken at the mouth. Phil. Tranſ. N° 482. ſect. 12.

This *poiſon*, which ſeems to be of a very ſubtile and dangerous nature, is extracted by fire from divers plants, eſpecially from thoſe which the French call *lianes*. The Indians in various places of South America prepare this *poiſon*, and make uſe of it for the killing of wild beaſts, in this manner:

Thoſe ſavages are very dexterous at making long trunks, which are the moſt common weapon uſed by them in hunting. To theſe trunks or tubes they fit little arrows made of palm-tree, on which they put a little toll of cotton exactly fitting the bore of the tube. They ſhoot theſe with their breath, and ſeldom miſs the mark. They dip the points of theſe little arrows, as well as of thoſe of their bows, in this *poiſon*, which is ſo active, that in leſs than a minute, eſpecially when freſh, it kills certain animals from which the arrow has drawn blood.

Though a very ſmall drop of this *poiſon*, conveyed into the blood by puncture, is ſometimes ſufficient to kill a man, or at leaſt to cauſe great diſturbance in the animal œconomy, it is quite otherwiſe when taken in at the mouth; for then it does no ſort of miſchief. See Phil. Tranſ. loc. cit. See MACASSAR *Poiſon*, and GREGO.

The negroes uſe a *poiſon* of an extraordinary nature. The doſe is very ſmall, and it hath no ill taſte ſo that, mixed with meat or drink, it is not perceivable. It raiſes divers ſymptoms, and the effects are various, according to the

the dose is large or small. It kills sometimes in a very few hours, sometimes, it is said, in some months, and at others in some years. The symptoms are according to the quantity given; if great, it causes evacuations upwards and downwards; of excrements first, then of humours, and lastly of blood, with fainting fits and sweatings. Death follows in six or seven hours. The negroes turn white. Phil. Trans. N° 262. p. 3.

The antidote to this *poison* is the root of the sensible weed, as it is commonly called, or *herba sensitiva*, in decoction.

Physicians distinguish three kinds of *poisons*.

Poisons, *animal*, which are those drawn from animals by the bite or sting; as, the viper, scorpion, lepus marinus, &c.

The theory of the effects, operations, &c. of *animal poisons*, is very accurately and mechanically delivered by Dr. Mead, in those remarkable cases, the bites of a viper, tarantula, and mad dog. See his doctrine under Tarantula, Viper, and Hydrophobia. See also Madness *from the bite of enraged animals*, and *Rattle* Snake.

Poisons, *vegetable*, as aconite, cicuta or hemlock, hellebore, napellus, &c. which are generally of a narcotic or stupefying quality.

With regard to the operation of vegetable *poisons*, it is observed that, besides heat and pain, they commonly occasion some degree of giddiness, and often a kind of stupidity or folly. See Opiate and Opium.

The persons who have taken these *poisons* must be treated in the same manner as for the mineral or corrosive. Dr. Mead, besides vomits, in this case, recommends acid medicines with fixed salts. He says, that he has often given salts of wormwood mixed with juice of lemon, in repeated doses, with great success.

It has been a general complaint, and indeed too just a one, that the qualities of plants are much less studied than their external appearances; and the best modern authors have contented themselves with nicely characterising plants according to their flowers and seeds, and ascertaining the proper names to each, without at all enquiring how they might be beneficial or hurtful to mankind; or distinguishing whether they were fafe medicines or deftructive *poisons*. Nor, indeed, is the inveftigating the virtues of plants, yet unfhed as medicines, any eafy talk; fince neither chemical analyfes, nor experiments on brutes, nor even the tafte and fmell, and other fenfible qualities of plants, can ever certainly aflure us what effects they will have on the human body.

Chemical analyfes alter the fubftance too much to give any certain knowledge; and the effects things have on one animal are no aflurance of what they will do to another, as is familiar to us in a thoufand inftances. Bitter almonds, and many other things, wholly harmlefs to us, kill birds; and goats will eat the tithymals, to give them an appetite when they want it, while thofe very plants are fatal to fifhes, and very dangerous to man. The fenfible qualities as often deceive us, of which we might give many inftances; and what fome have obferved of the botanical characters of plants, telling us their virtues, or that all of the fame clafs poffefs the fame qualities, is the moft erroneous, and, if trufted to, might prove the moft fatal of all opinions; fince the known *poifons*, hemlock, phellandrium, and water-dropwort, with the *poifonous* juice, are all umbelliferous plants, and consequently of the fame family with fennel and angelica.

Nothing can, indeed, aflure us with any degree of certainty of the virtues of plants, but experiments made on ourfelves; but few are to be found who with fo well to the public, as to venture their own lives for its fervice: and perhaps the honeft Geiner is the only man who ever entried thefe attempts to any degree, and he unhappily died a martyr to them, perifhing by the dofe he took of the fcorpion-rooted doronicum; the very root which has of late with us been fo fatal, by being accidentally mixed with our gentian.

What we learn of the vegetable *poifons* muft therefore be either by the confequences of the rafh prefcriptions or miftakes of ignorant pretenders to medicine, or by the misfortune of thofe who have unwarily eaten them.

We have accounts in the Memoirs of the Academy of Sciences of Paris, of many things of this kind. An apothecary, a very honeft man, but of no knowledge in botany, had made his extract of black hellebore from the roots of chriftophoriana, or bane-berries, a plant always accounted a *poifon*, and a fingle berry of which is capable of killing feveral animals; yet fo far had the fire diveiled the roots of their poifonous qualities, that twelve grains of this given as extract of hellebore, proved of no ill effect. Mem. Acad. Scienc. Par. 1739.

Another apothecary having learned, that hermodactyls were the roots of a fpecies of colchicum, dried the roots of the common colchicum, and fold them in its place; yet there is no knowledge of any ill effects from them.

The enquiry into things of this kind has its ufe, which is very important; fince *poifons* often differ only in dofe from medicines, and many of the vegetables efteemed *poifonous*, may perhaps be found ufeful remedies, with proper management and in proper quantities.

The laurel-leaves are well known to afford a *poifonous* water in diftillation, yet it is as well known that they have been long ufed in cookery, to give a tafte like that of bitter almonds to creams, &c. and that without any ill effect. The rofe-bay, or oleander, is well known to be a *poifon* to goats, yet is taken by countrymen of ftrong and robuft habits as a purge, and that with very good fuccefs. Nay, opium, one of the greateft of all medicines, if it had firft been difcovered by perfons taking overdofes of it, and dying by it, as they naturally muft have done, might very naturally have been recorded to us as a very fatal *poifon*.

The plumbago, or dentillaria of Rondeletius, is fo violent a cauftic, that a poor girl who once anointed herfelf with it, to cure her of the itch, was faid alive by it; yet this properly managed, and inftead of evils, has proved one of the greateft of all remedies for cancers.

The fhrub ufed in dying, and called by the French *redoul*, by fome authors *orfeille*, and by others the myrtle-leaved *rhus*, is generally known in the world only as a drug ufeful in the dreffing of leather; but Pliny, and fome other old writers, have given it the character of an ufeful external medicine, and a remedy againft *poifon*, yet with all this inattention of the moderns, and all the praifes of the ancients, this plant is truly a very terrible *poifon*. The grown cattle refufe to feed upon it, but the young lambs and kids often eat of it in thofe parts of Europe where it is common; and if they eat the full-grown leaves, they are killed by it; if the young fhoots only, which is more ufually the cafe, they are then only affected with fpafms and a fort of drunkennefs, of which, after a few hours, they recover. Nor is this fingular in the *poifonous* plant, fince it is well known, that many plants, of very improper kinds for food, are yet eaten in their young fhoots: and Linnæus has recorded it of the Lapianders, that they even eat the young fhoots of the *poifonous* blue aconite, or wolf-bane; and even in France they eat the firft fhoots of the clematis, or flammula refens, the full grown leaves of which are of fo acrid a nature, that they ferve the beggars to eat ulcers in their arms and legs, to give them a pretended title to charity.

The *redoul* is not only a *poifon* to animals, but its fatal effects have been feen on the human fpecies. A girl in France, where it is very common, gathering its fruit among black-berries, eat of them, and died epileptic, in fpite of all the aflifance that could be given to her: and another inftance is given from the Hotel Dieu at Paris, where an unhappy traveller, a robuft man, was brought in epileptic, and died fo; though the caufe was not known, except by a vomit which was given him bringing up fome of the berries of this pernicious plant, and fome more of them having been found in his ftomach when diffected. Mem. Acad. Scienc. Par. 1739.

Poisons, *mineral*, as arfenic, corrofive fublimate, ceruffe, orpiment, realgal, &c. which are commonly of an acrid or corrofive quality.

As to *mineral poifons*, they all bear fo much analogy to that made of quickfilver in the common fublimate, that their operation will be eafily conceived, from what is laid down under the heads Mercury, and Sublimate.

They are all more or lefs dangerous, as their falts receive a greater or lefs force from the metallic particles; and hence, as the moft virulent may be mitigated, by breaking the points of the faline cryftals, fo the moft innocent minerals may become corrofive, by combining them with falts, as is feen in the preparations of filver, antimony, iron, &c.

As to the effect of arfenic, to which that of every other fpecies of corrofive *poifon* is fimilary it is obferved, that the perfon who has taken it, foon perceives a burning heat, and a violent pricking pain in his ftomach and bowels, with an intolerable thirft, and an inclination to vomit. The tongue and throat feel rough and dry, and, without proper help, the patient is foon feized with great anxiety, hiccoping, faintings, and coldnefs of the extremities. Thefe are fucceeded by black vomits, fetid ftools, with a mortification of the ftomach and inteftines, which are the immediate fore-runners of death.

When thefe fymptoms firft appear, the patient fhould drink large quantities of new milk and fallad oil, till he vomits, or warm water with oil; or fat broths; or freth butter melted or mixed with the milk or water: thefe are to be drank as long as the inclination to vomit continues; nor is it fafe to leave off drinking as long as one particle of the *poifon* remains in the ftomach. If thefe liquids do

hot produce vomiting, half a dram or two ſcruples of the powder of ipecacuanha may be given, or a few ſpoonfuls of the oxymel, or vinegar of ſquills, may be mixed with the water which is drank. Or if other methods fail, half a dram of white vitriol, or five or ſix grains of emetic tartar muſt be adminiſtered. If tormenting pains are felt in the lower belly, and there be reaſon to apprehend that the *poiſon* has got down to the inteſtines, clyſters of milk and oil muſt be thrown up; and the patient muſt drink emollient decoctions of barley, oatmeal, marſhmallows, and ſuch like. He muſt likewiſe take an infuſion of ſenna and manna, a ſolution of Glauber's ſalts, or ſome other purgative. After the *poiſon* has been evacuated, the diet for ſome time ſhould be cooling and healing, ſuch as milk, broth, gruel, light puddings, and ſpoon-meats of eaſy digeſtion, and the drink ſhould be barley-water, linſeed-tea, or infuſions of any of the mild mucilaginous vegetables; but all fleſh, and ſtrong liquors ſhould be avoided. Buchan's Dom. Med. p. 515. ed. 5th.

It has been remarked under LIVER *of ſulphur*, that M. Navier recommends it as an antidote againſt certain metallic *poiſons*. This has been long and ſucceſsfully applied by others; and in the ſixth volume of the Edinburgh Medical Commentaries, there is a paper, in which alkaline ſalts are recommended on the ſame principle.

Dr. Houlton obſerves, that in all caſes of *poiſon*, it is prudent immediately to give a ſolution of an alkali, followed by a vomit. If the *poiſon* be corroſive ſublimate, an alkali, either fixed or volatile, will decompoſe it, and precipitate the metal in a form nearly inſenſitive. It will have a ſimilar effect on the ſugar of lead, emetic tartar, or any metallic ſalt. If the *poiſon* be arſenic, Neumann obſerves, that alkalis will very plentifully diſſolve it: and, therefore, the vomit will ſucceed the better to diſcharge it. If the *poiſon* be of the vegetable claſs, an alkali can be of no diſſervice, nor interfere with the other means of remedying by evacuation, nor by the ſubſequent uſe of acids, ſo much inſiſted upon by Triſtot, as counteracting the effects of narcotics; becauſe acids, adminiſtered with alkaline ſalts, are pronounced, by Dr. Mead and others, to be attended with great ſucceſs in this caſe. This writer, therefore, directs, when ſymptoms of *poiſon* appear, to mix a tea-ſpoonful of any of the following ingredients: ſalt of tartar, ſalt of wormwood, pearl-aſh, pot-aſh, ſpirit of hartſhorn, or ſal-volatile, with half a pint of water; and of this let one half be given to the patient immediately, and the other ſoon after. It will ſometimes give relief, and the vomiting will ſoon ceaſe. The vomiting, however, is to be promoted by warm water, ipecacuanha, &c. and after each vomiting, a doſe of this ſolution of ſalt of tartar ſhould be given, and repeated every two or three hours, if the pain of the ſtomach returns. It ſhould be continued too, in ſmall doſes, for ſome time after the ſymptoms diſappear. A little wood-aſhes, mixed with boiling water, ſuffered to ſtand, and pouring off the water, or filtering it through linen, will anſwer the ſame purpoſe.

The general remedies againſt *poiſons* are known by the name of *antidotes*, *alexipharmics*, and *alexiterials*.

The following rules ſhould be ſtrictly obſerved with regard to every kind of *poiſon*: that when any poiſonous ſubſtance has been taken into the ſtomach, it ought, as ſoon as poſſible, to be diſcharged by vomits, clyſters, and purges; and when *poiſon* has been received into the body by a wound, that it be expelled by medicines which promote the different ſecretions, eſpecially thoſe of ſweat, urine, and inſenſible perſpiration; to which may be joined antiſpaſmodics, or ſuch medicines as take off tenſion and irritation, the chief of which are opium, muſk, camphor, and aſſafœtida.

POISON-*berry*, a ſpecies of the CESTRUM.

POISON-*buſh*, *toll-vendlus*, in *Botany*. Its characters are theſe: the flower has an empalement of one leaf, indented in three parts; it has one petal, which is ſhaped like a flipper, of a thick fleſhy conſiſtence; under the upper part of the flower are ſituated ten ſtamina, which are incloſed in the receptacle of the flower; they are ſlender and terminated by globular ſummits; in the centre is ſituated a roundiſh three-cornered germen, ſupporting three biffid ſtyles crowned by oblong ſtigmas; the germen becomes a roundiſh capſule, having three cells, each containing an oval ſeed. There are two ſpecies, natives of the Weſt Indies, abounding with an acrid milky juice, which will raiſe bliſters on the fleſh, and, it is ſaid, when mixed with the blood, becomes a deadly *poiſon*; and it is uſed for applying to the points of armour, and the edge of ſwords. Linnæus has joined this genus to the *euphorbia*, or SPURGE.

POISON, *Macaſſar*. See MACASSAR *Poiſon*.

POISON, *Indian*. See GECCO.

POISON-*tree*, or POISON-*wood*, *toxicodendron*, in *Botany*. Its characters are theſe: the male flowers are upon different plants from the female; they have a ſmall empalement, cut into five points at the brim, but have no petals; they have five ſhort ſtamina, terminated by roundiſh ſummits; the female flowers have empalements and petals like the male; they have no ſtamina, but in the centre is ſituated a roundiſh germen, ſupporting three ſmall ſtyles, crowned with globular ſtigmas; the germen afterwards turns to a berry, with one or two cells, incloſing one ſeed in each. Miller enumerates nine ſpecies. Linnæus has joined theſe plants to his genus of RHUS, for the characters of which ſee SUMACH.

The moſt common American kind of this tree, is the aſh-leaved one; it grows in marſhy places, and is called by the common people marſh-ſumach, and is the RHUS *vernix* of Linnæus; its leaves reſemble thoſe of the common ſumach, which are very well known to reſemble aſh-leaves in their pinnated ſtructure. It grows to about four inches in diameter, and to twenty feet, or upward, in height, in thoſe countries where it grows naturally. It ſpreads much at the root, and where one has been at any time cut down, there are always ſeen a great number of young ones growing from its ſtump. It is of very quick growth, but is not durable. The infuſe of the wood is yellow, and contains a whitiſh yellow juice, which comes out between the bark and wood, is as glutinous as turpentine, and has a tuſeous ſmell; the wood itſelf has a very ſtrong and diſagreeable ſmell, but the juice ſtinks like carrion.

This tree poiſons two ways; by handling of it, and by the ſmell. The ſcent of it when cut down in the woods has poiſoned many people, and many more have ſuffered by it while burning in their fires. People with only handling it have been made blind for ſeveral days, and perſons who ſit near a fire when it is burning are often ſwelled and chucked up in all parts of the body in a terrible manner. It is very remarkable that the effect of this *poiſon* ſeems confined to ſome few perſons, and that one may handle it ever ſo long, and even chew it without hurt, while another is poiſoned by only touching it; and a whole company ſitting by a fire where it is burning, ſhall often all eſcape except one or two, who will be ſwelled with it. The *poiſon* of this tree is never mortal, but goes off of itſelf in a few days; and the people who ſuffer by it generally carry its effects off the ſooner, by uſing ſallad oil and cream to the parts. The firſt notice the perſon has of being affected by it, is by feeling a violent itching in the ſkin; this provokes ſcratching and rubbing; and in conſequence of this the part inflames and ſwells. Sometimes a perſon's whole body is ſwelled and poiſoned in this manner, and ſometimes only a particular part, as the legs; and in this caſe, they often diſcharge a conſiderable quantity of water, and then grow well.

People who have been poiſoned by handling it, aſſirm that it is ſo much colder to the touch than other wood, that it may be diſtinguiſhed by this in the dark; when it is burning ſome people are ſo affected by it as to ſwoon away, others yawn and ſeem uneaſy, while the reſt feel nothing of it.

The fruit of this tree is a white roundiſh dry berry, growing in cluſters. Phil. Tranſ. N° 367. p. 144. Prof Kalm's Travels in North America.

For the uſe of this juice in ſtaining linen. See LINEN.

POISON, *counter*. See COUNTER *poiſon*.

To POISON *a piece*, among *Gunners*, is the ſame as to clog and nail it up. See NAILING.

POISONING, in *Law*, the crime of adminiſtering poiſon to a perſon, whereby he dies.

This, by 22 Hen. VIII. cap. 9. was made a ſort of treaſon; and the puniſhment doomed for it was, to be put alive into a caldron of water, and boiled to death. But this act was repealed by 1 Edw. VI. cap. 12.

At preſent, it is only murder, or felony without benefit of clergy, if the party dies of the poiſon within a year and a day.

POISONOUS *waters*. See WATER.

POKE, or PORK *phyſic*. See *American* NIGHTSHADE.

POLA, in *Ichthyology*, the name of a flat fiſh, ſomething reſembling the ſoal, but ſhorter and ſmaller; commonly called CYNOGLOSSUS and *linguatula*.

It is caught in the Mediterranean, and ſold in Rome and Venice for the table.

POLACRE, in *Naval Language*, a ſhip with three maſts, uſually navigated in the Levant, and other parts of the Mediterranean. Theſe veſſels are generally furniſhed with ſquare ſails upon the main-maſt, and lateen ſails upon the fore-maſt and mizen-maſt. Some of them, however, carry ſquare ſails upon all the three maſts, particularly thoſe of Provence, in France. Each of their maſts is commonly formed of one piece, ſo that they have neither top-maſt nor top-gallant-maſt; neither have they

any

any horſes to their yards, becauſe the men ſtand upon the top-ſail-yard to looſe or furl the top-gallant ſail, and on the lower yard to reef, looſe, or furl the top-ſail, whoſe yard is ſufficiently lowered down for that purpoſe. Falconer.

POLAEDRASTYLA, in *Natural Hiſtory*, the name of a genus of cryſtals. The word is derived from the Greek πολυς, *many*, εδρα, *face*, and στυλος, *a column*; the privative particle α, *un*, and ενωσις, *a reſolution*; and expreſſes a cryſtal compoſed of many planes, and having no column.

The bodies of this genus are cryſtals compoſed of two octangular pyramids, joined baſe to baſe, and conſequently the whole body conſiſting of fifteen planes. Of this genus there are only two known ſpecies: 1. A brown kind with ſhort pyramids, found in conſiderable plenty in Virginia, on the ſides of hills; and 2. A colourleſs one, with longer pyramids. This has yet been found only in one place, which is the great mine at Goſſalaer, in Saxony, and there uſually lies at great depths. Hill's Hiſt. of Foſſils, p. 171.

POLAR, ſomething that relates to the poles of the world. In this ſenſe we ſay, *polar* virtue, *polar* tendency, &c. See POLARITY.

POLAR, or *white-bear*, in *Zoology*, a ſpecies of BEAR, with a long head and neck, ſhort round ears, end of the noſe black, large teeth, hair long, ſoft, white, and tinged in ſome parts with yellow, and limbs of great ſize and ſtrength. This animal, which grows to a great ſize, ſo that the ſkins of ſome are thirteen feet long, is confined to the coldeſt part of the globe; being unknown, except on the ſhores of Hudſon's-bay, Greenland, and Spitzbergen. In ſummer the white bears make their reſidence on iſlands of ice; they ſwim with great agility for ſix or ſeven leagues, and are excellent divers. Their winter retreats are in dens under the ſnow or the fixed ice of the frozen ſea. Their food is fiſh, ſeals, and the carcaſes of whales, and human bodies, which they will greedily diſinter; and they are ſo fond of human blood, that they will attack companies of armed men, and even board ſmall veſſels. On land they live on birds and their eggs. They bring two young at a time, and their mutual attachment is ſo ſtrong, that they would die ſooner than deſert one another. Their greateſt enemy is the *morſe*. The fleſh is white, and ſaid to taſte like mutton; the fat is melted for train oil, and that of the feet uſed in medicine: but the liver is very unwholeſome. Pennant's Hiſt. of Quad. vol. ii. p. 288. See *Tab. Quadrupeds*, N° 4.

POLAR *circles*. See *Polar* CIRCLES.

POLAR *dials* are thoſe, whoſe planes are parallel to ſome great circle paſſing through the poles, or to ſome one of the hour-circles; ſo that the pole is neither elevated above, nor depreſſed below the plane.

Such dial, therefore, can have no centre, and conſequently its ſtyle, ſub-ſtyle, and hour-lines, are parallel.

This, therefore, will be an horizontal dial to thoſe who live under the equator or line.

POLAR *dial, to conſtruct a*. See DIAL.

POLAR *projection* is a repreſentation of the earth, or heavens, projected on the plane of one of the *polar* circles.

POLARITY, the quality of a thing conſidered as having poles.

By heating an iron bar, and letting it cool in a vertical poſture, it acquires a *polarity*. The lower end becomes the north pole, the upper the ſouth.

Iron bars acquire a *polarity*, by being kept a long time in an erect poſture, even without heating. Thus, the bars of windows, &c. are frequently found to have poles. Nay, a rod of iron acquires a *polarity*, by the mere holding it erect; the lower end, in that caſe, attracting the ſouth end of a magnetic needle, and the upper, the north end. But theſe poles are mutable, and ſhift with the ſituation of the rod. See MAGNET.

Some modern writers, particularly Dr. Higgins, in his Philoſophical Eſſay concerning Light, have maintained the *polarity* of the parts of matter, or that their ſimple attractions are more forcible in one direction, or axis of each atom, than in any other.

POLE, POLUS, Πολος, formed from πωλεω, *to turn*, in *Aſtronomy*, one of the extremities of the axis, whereon the ſphere revolves.

Theſe two points, each 90 degrees diſtant from the equator, are called, by way of eminence, the *poles of the world*.

Wolfius defines the *poles*, thoſe points on the ſurface of the ſphere, through which the axis paſſes; ſuch are the points I and K (*Tab. Aſtron. fig.* 21.) whereof that viſible to us, or raiſed above our horizon, I, is called the *arctic* or *north pole*; and its oppoſite, K, the *antarctic* or *ſouth pole*.

POLE, in *Geography*, is the extremity of the earth's axis, or one of the points on the ſurface of our globe, through which the axis paſſes. See EARTH.

Such are the points P, Q (*Tab. Geog. fig.* 7.) whereof that elevated above our horizon is called the *arctic* or *north pole*; and its oppoſite, Q, the *antarctic* or *ſouth pole*.

Dr. Halley ſhews, that the ſolſtitial day, under the *pole*, is as hot as under the equinoctial, when the ſun is in the zenith; in regard, all the twenty-four hours of that day under the *pole*, the ſun-beams are inclined to the horizon in an angle of 23½ degrees; whereas, under the equinoctial, though the ſun becomes vertical, yet he ſhines no more than twelve hours, and is abſent twelve hours. Beſides, that, for three hours eight minutes of the twelve hours which he is above the horizon there, he is not ſo much elevated as under the *pole*. See HEAT, *in Geography*.

The *altitude* or ELEVATION *of the pole*, is an arch of the meridian intercepted between the *pole* and the horizon. To find this elevation is a very popular problem in aſtronomy, geography, and navigation; this and the latitude of the place being always the ſame.

POLE, *to obſerve the altitude of the*. With a quadrant obſerve both the greateſt and leaſt meridian altitude of the *pole*-ſtar.

Subtract the leaſt from the greateſt, and divide the difference by two; the quotient is the ſtar's diſtance from the pole; which, added to the leſſer altitude found, gives the elevation of the *pole* required. See LATITUDE.

Thus M Coupler, the younger, at Liſbon, in 1697, in the end of September, obſerved the greateſt meridian altitude 41° 5′ 40″. The ſmalleſt 36° 28′ 0″, the difference whereof is 4° 37′ 40″; one half whereof, 2° 18′ 50″, added to the leſs, gives 38° 46′ 50″, the altitude of the *pole* of Liſbon.

The altitude of the *pole*, together with the meridian line, being the baſis of all aſtronomical obſervations; to determine it with the greateſt accuracy, the meridian altitudes muſt be corrected from the doctrine of refractions, hereafter to be delivered.

By means hereof, M. Coupler, ſubtracting 1′ 25″ in the propoſed example, leaves the corrected altitude 38° 45′ 25″.

Hence, 1. The altitude of the *pole* being ſubtracted from 90°, leaves the *altitude of the equator*.

2. If the greateſt meridian altitude of this ſtar exceed the altitude of the equator, the latter, ſubtracted from the former, leaves the declination of the ſtar northward; if the altitude of the ſtar be leſs than that of the equator, the former, ſubtracted from the latter, leaves the ſtar's declination ſouthward.

Dr. Hooke, and ſome others, imagined the height of the *pole*, and the poſition of the circles in the heavens, in reſpect of thoſe on the earth, to be changed from what they anciently were. But M. Caſſini thinks there is no ground for ſuch a ſurmiſe; but that all the difference we now find in the latitudes of places, &c. in reſpect of the ancient accounts, ariſes from the inaccuracies of the ancient obſervations.

Indeed, it is no wonder they ſhould err in their obſervations, conſidering what inſtruments they uſed. He adds, it is probable there may be ſome variation in the height of the *pole*; but, he thinks, this never exceeds two minutes; and that even this will vaniſh, after it is arrived to its higheſt difference.

POLE, in *Sphereſ*, is a point equally diſtant from every part of the circumference of a greater circle of the ſphere; as the centre is in a plain figure.

Or, *pole* is a point 90° diſtant from the plane of a circle, and, in a line paſſing perpendicularly through the centre, called the axis.

The zenith and nadir are the *poles* of the horizon. The *poles* of the equator are the ſame with thoſe of the ſphere or globe.

POLES of the ecliptic are two points on the ſurface of the ſphere, 23° 30′ diſtant from the *poles* of the world, and 90° diſtant from every part of the ECLIPTIC.

POLES, in *Magnetics*, are two points in a load-ſtone, correſponding to the *poles* of the world; the one pointing to the north, the other to the ſouth.

If the ſtone be broken in ever ſo many pieces, each fragment will have its two *poles*. If a magnet be biſected by a line perpendicular to the axis; the two points, before joined, will become oppoſite *poles*, one in each ſegment.

To touch a needle, &c. that part intended for the north end is touched with the ſouth *pole* of the magnet, and that intended for the ſouth end with the north *pole*.

A piece of iron acquires a polarity, by only holding it upright; but its *poles* are not fixed, but ſhift, and are inverted as the iron is. A fixed north *pole* may be made all the ways a fixed ſouth *pole* is made; but not *vice verſâ*: and whatever way we get a fixed ſouth *pole*, it is always weaker than a fixed north *pole* got the ſame way. Fire deſtroys all fixed *poles*; but it ſtrengthens the mutable ones.

The end of a rod being heated, and left to cool north-ward,

ward, Dr. Gilbert says, becomes a fixed north *pole*; if southward, a fixed south *pole*: yet this doth not hold in all cases. If the end be cooled, held downward, or to the nadir, it acquires somewhat more magnetism than if cooled horizontally towards the north; but the best way is to cool it a little inclined to the north. Repeated ignitions do not avail to this purpose any more than a single one.

Dr. Power says, that if we hold a rod northwards, and hammer the north end in that position, it will become a fixed north *pole*; and contrarily, if you hammer the south end. What is said of hammering, is to be likewise understood of filing, grinding, sawing; nay, a gentle rubbing, provided it be continued long, will produce *poles*.

The more heavy the blows are, *exteris paribus*, the magnetism will be the stronger. A few hard blows do as much as many.

Old drills and punches have all fixed north *poles*, because almost constantly used downwards. New drills have either mutable *poles*, or weak north *poles*. Drilling with such a one southward horizontally, it is a chance if you produce a fixed south-*pole*, much less if you drill south downwards; but if you drill south upwards, you always make a fixed south *pole*.

A weak fixed *pole* may degenerate into a mutable one in a day, nay, in a few minutes, by holding it in a position contrary to its *pole*. The load-stone itself will not make a fixed *pole* in any iron. It is required the iron have a length, if it be thick.

Mr. Ballard tells us, that in six or seven drills made before his face, the bit of each became a north *pole*, merely by hardening. See MAGNET, and MAGNETISM.

POLES, *under bare*, in *Sea Language*, denotes the situation of a ship at sea, when all her sails are furled, particularly in a tempest.

POLE *of a glass*, in *Optics*, is the thickest part of a convex, or the thinnest of a concave glass.

If the glass be truly ground, the *pole* will be exactly in the middle of its surface.

This is sometimes also called the *vertex* of the glass.

POLE, in *Surveying*, is a measure containing sixteen feet and a half; called also PERCH, and sometimes *rod*.

POLE-*axe*, is a sort of hatchet nearly resembling a BATTLE-axe, having a handle about fifteen inches in length, and being furnished with a sharp point, or claw, bending downwards from the back of its head; the blade of which is formed like that of any other hatchet. It is principally employed to cut away and destroy the rigging of an adversary who endeavours to board. *Pole-axes* are also said to have been successfully used on some occasions in boarding an enemy, whose sides were above those of the boarder. This is executed by detaching several gangs to enter at different parts of the ship's length, at which time the *pole-axes* are forcibly driven into her side, one above another, so as to form a sort of scaling-ladders. Falconer.

POLE-*cat*, *mustela putorius* of Linnæus, in *Zoology*, the name by which authors call a creature of the weasel-kind, but larger than the common weasel, and remarkable for its stinking smell. It is also called *fitchet*.

The whole circumference of the face is white, at the extremity of the angles of the mouth there begins a broad line of a yellowish hue, which surrounds the head, and is white in several parts; its long hairs are black, its short ones yellowish; and the throat, the feet, and the tail, are blacker than any other part of the body; the upper jaw stands out a little beyond the lower; the ears are broad and short, and are fringed, as it were with white; its stink is occasioned by an extremely foetid matter, secreted by two glands, which it has in common with all the creatures of this kind, within the anus.

It feeds on flesh, frequently stealing hens and other poultry, and sometimes contenting itself with their eggs.

In winter it frequents houses, and will rob the dairy of the milk. It commonly burrows in the ground, forming a retreat about two yards in length, terminating under the roots of some large tree; and sometimes forms its lodgment in barns and under hay-ricks. It brings five or six young at a time. The skin of this animal is dressed with the hair on, and used as other furs for tippets, &c. and is sent abroad to line cloaths. It inhabits most parts of Europe. Ray and Pennant. See *Tab.* IV. *Quadr.* N° 48.

POLE-*cat*, *American*, or *striated*, called *skunk*, in *Zoology*, is the *viverra putorius* of Linnæus, with rounded ears; head, neck, belly, legs, and tail, black; the back and sides marked with five parallel white lines; one on the top of the back, the others on each side; the second extends some way up the tail, which is long and bushy towards the end. This animal, which is about the size of the European *pole-cat*, inhabits North America; when attacked, it bristles up its hair, and flings its body into a round form: its vapour is horrid. Pennant.

POLE-*mast*. See MAST.

POLE-STAR, or POLAR-STAR, is a star of the second magnitude, the last in the tail of URSA minor, or the Little Bear.

The nearness of this star to the *pole*, whence it happens that it never sets, renders it of vast service in navigation, &c. for determining the meridian line, the elevation of the *pole*, and consequently the latitude of the place, &c.

POLE *of a wheel-carriage*. See PERCH.

POLEIN, in our *Ancient Customs*, a sort of shoe, sharp or picked at the point.

This fashion was first taken up in the time of King William Rufus; the picks being made so long, that they were tied up to the knees, with silver or golden chains.

They were forbidden by stat. an. 4 Edw. IV. cap. 7. *Tunc statuit civibus, tunc insuit vestibus, tunc usus intervenus cum arcuatis ocultis inventus est.* Malmesb. in Will. II.

POLEMARCHUS, Πολέμαρχος, among the Athenians, a magistrate who had all the strangers and sojourners in Athens under his care, over whom he had the same authority that the archon had over the citizens.

It was the duty of the *polemarchus* to offer a solemn sacrifice to Enyalius, said by some to be the same with Mars, but by others to have been only one of his attendants, and another to Diana, surnamed Αγροτέρα, in honour of the famous patriot Harmodius. It was also the business of the *polemarchus* to take care that the children of those who had lost their lives in their country's service, should have a competent maintenance out of the public treasury. Potter.

POLEMICAL, Πολεμικὸς, *from* πόλεμος, *war, battle*, an epithet applied to books of controversy, especially those in divinity.

Scaliger's exercitations against Cardan make a pure *polemical* book.

Hence also we say, *polemical divinity*, for controversial, &c.

POLEMONIUM, in *Botany*. See *Greek* VALERIAN.

POLEMOSCOPE, in *Optics*, an oblique kind of perspective glass, contrived for the seeing of objects that do not lie directly before the eye.

It was invented by Hevelius, in 1637, who gave it this name, from the Greek πόλεμος, *battle*; because it may be of use in war, in engagements, duels, &c. for discovering what the enemy is doing, whilst the spectator lies hid behind any obstacle.

Something of this kind, are those now known among us under the name of ogling-glasses, or OPERA-glasses, through which one sees a person, in appearing to look at another.

POLEMOSCOPE, *construction of the*. Any telescope will be a *polemoscope*, if the tube be but crooked, like a rectangular siphon A B D M (*Tab.* V. *Optics, fig.* 90.) and between the object-glass A B and the first eye-glass G H, (if there be several) be placed a plain mirror, in such manner as that the mirror is inclined to the horizon at an angle of 45°, and its reflected image found in the focus of the eye-glass G H.

For, by this means, objects, situate over-against the lens A B, will appear the same as if the mirror K were away, and the object-glass, with the objects, were directly opposite to the eye-glasses.

If it be desired to look in at O, not at M, another plain mirror N must be added.

POLETA, in our *Ancient Law Books*, signifies the half of the foot. *Tres octavas fendaturæ de pede asterisci sive postes.* Matt. Par. anno 1215.

POLETÆ, Πωλῆται, among the Athenians, ten magistrates, who, together with three that had the care of the money allowed for shews, had the power of letting out the tribute-money, and other public revenues, and selling confiscated estates; all which bargains were ratified in the name of their president. Besides this, it was their office to convict such as had not paid the tribute called *Metoicia*, and sell them by auction. Potter.

POLEY-*grass*, in the Linnæan system of *Botany*, is a species of LYTHRUM.

Mountain POLEY, or POLEY *mountain*, *polium*, in *Botany*. Its characters are these: the empalement of the flower is permanent and of one leaf, cut into five acute segments; the flower is of the lip kind; it hath one petal, with a short tube; the stamina occupy the place of the upper lip, and the lower lip is cut into five segments; it hath four awl-shaped stamina, which are terminated by small summits; and a germen divided into four parts, supporting a slender style, crowned by two narrow stigmas; the germen afterwards becomes four naked seeds, inclosed in the empalement. Miller enumerates fifteen species. Linnæus has joined this genus to the TEUCRIUM.

These plants may be disposed in a garden, so as to afford pleasure, by mixing them with marum, mastich, and several other aromatic plants, upon the sloping sides of banks

banks, which are expoſed to the ſun; or upon little hillocks raiſed in a ſheltered ſituation; where, by the diverſity of their hoary branches, being of various ſhapes, they will make a pretty appearance, and in ſuch places they will reſiſt the cold much better than when they are planted in a good ſoil. They may be propagated by ſeeds, which muſt be procured from the countries where they naturally grow, ſown on a bed of freſh light earth in the ſpring. About the middle of July the plants may be removed, and part of them planted on a warm border of dry rubbiſhy ſoil, where they are to be ſhaded from the ſun, watered till they have taken root, and kept clear of weeds. The other part may be planted in ſmall pots filled with freſh, light, undunged earth, and placed in the ſhade till they have taken root; they may then be removed into an open ſituation, and remain there till the beginning of November, when they ſhould be placed under a common frame.

They may alſo be propagated by cuttings or ſlips, which ſhould be planted the beginning of April, juſt before they ſhoot, upon a border expoſed to the eaſt; and if the ſeaſon proves dry, they muſt be watered and ſhaded until they have taken root; afterward they will require no other care but to keep them clean from weeds, and at Michaelmas the plants ſhould be removed where they are deſigned to remain; but it will be proper to put a plant of each ſort into pots, that they may be ſheltered in winter, to preſerve the kinds. Miller.

Several ſpecies and varieties of *polium*, erect and procumbent, with white, yellow, and purpliſh flowers, have been received in the ſhops. But the *poley-mountain* of Candy has been commonly underſtood as the officinal ſort, which is procured dry from the iſland Candy; and the *poley-mountain* of Montpelier is allowed to be of the ſame quality. The leaves and tops have a moderately ſtrong aromatic ſmell, and a disagreeable bitter taſte; they are recommended as corroborants, aperients, and antiſpaſmodics; but are at preſent ſcarcely otherwiſe made uſe of than as an ingredient in mithridate and theriaca. *Lewis.*

POLONIA, in *Botany*, a name by which ſome authors have called the coco-nut tree, or *palma Indica nucifera* of other writers.

POLIA *litharges*, a term uſed by Dioſcorides to expreſs the white litharge, which we call litharge of ſilver.

The proper ſenſe of the word *polios*, is hoary, or grey, and it very well expreſſes the colour of this ſubſtance; but the commentators have not been ſatisfied with this obvious meaning, but have made it *pelion*, and ſome of them *ſtibium*. See LITHARGE.

POLIANTHES, in *Botany*, a genus of the *hexandria monogynia* claſs. Its characters are, that the corolla is funnel-ſhaped, incurvated, and equal; the filaments are inſerted in the chaps of the corolla, and the germen in the baſe of it. There is only one ſpecies.

POLICY, or POLITY, Πολιτεια, the laws, orders, and regulations, preſcribed for the conduct and government of ſtates and communities.

The word is of Greek original, being derived from the Greek πολις, *civitas*, *city*, or *ſtate*.

In the general, *policy* is uſed in oppoſition to barbariſm. Different ſtates have different kinds of *policy*: thus the *policy* of Athens differed from that of Sparta.

Loyſeau obſerves, that *policy* properly ſignifies the courſe and adminiſtration of juſtice in a city. The direction of the *policy* of London is in the hands of the lord mayor.

At Paris they have a *chamber of policy*, where people are verbally accuſed for contraventions of *policy*.

Some divide *policy* into two parts, *œconomy*, that relating to affairs of merchandize; and *aſtynomy*, that concerning the civil and judiciary government of the citizens. Some add a third branch, viz. what relates to the ECCLESIASTICAL government.

Richard Hooker has a fine treatiſe of the laws of eccleſiaſtical *policy*.

In much the ſame ſenſe is uſed the modern term *police*, or *police*. œconomy, to denote the due regulation and domeſtic order of the kingdom; whereby the individuals of the ſtate, like members of a well governed family, are bound to conform their general behaviour to the rules of propriety, good neighbourhood, and good manners; and to be decent, inoffenſive, and inſenſible, in their reſpective ſtations. The claſs of crimes againſt the public *police* of a country comprehends thoſe which amount to FELONY, as clandeſtine MARRIAGES, BIGAMY, and POLYGAMY; thoſe of idle ſoldiers and MARINERS, wandering about the realm, and GYPSIES; and others, whoſe puniſhment is ſhort of death, as common BARRATORS, INSOLENCE, LUXURY, GAMING, and the deſtroying of GAME.

POLICY *of inſurance*, or *aſſurance of ſhips*, is a contract or convention, whereby a perſon takes upon himſelf the riſks of a ſea-voyage; obliging himſelf to make good the loſſes and damages that may befall the veſſel, its equipage, tackle, victualling, lading, &c. either from tempeſts, ſhipwrecks, *pirates*, fire, war, reprizals, &c. in part or in whole, in conſideration of a certain ſum of ſeven, eight, or ten per cent. more or leſs, according to the riſk run; which ſum is paid down to the aſſurer by the aſſuree, upon his ſigning the *policy*.

There are ſome aſſurances for the going, ſome for the returning, and ſome for both, or for a limited time; though ſome maintain, that the time ought never to be limited, in that the contract thereby becomes uſurary.

The *policy* is to contain the name and dwelling of the perſon aſſured; his quality, whether as proprietor, or agent; the effects, the name of the veſſel, and of the maſter; thoſe of the place where the goods are to be loaden or unloaden; the port whence, and whither; as alſo the time, the riſks, and the conditions.

If the veſſels or merchandizes aſſured be loſt, the aſſuree muſt notify the ſame by an act in form; declaring he ſurrenders the whole to the aſſurer, on his paying the ſums aſſured in the time expreſſed.

The origin of theſe aſſurances is aſcribed to the Jews, at the time they were expelled France, in 1182; who are ſaid to have uſed this as a means to facilitate the tranſporting of their effects. The term *policy* is Spaniſh, and comes from *poliça*, *cedula*, but the practice comes from the Italians and the Lombards; who, again, derived it originally from the Latin *polliciturio*, *promiſe*. Some ſay the merchants of Marſeilles were the firſt who ſet on foot this kind of commerce.

Anciently *policies* were given by word of mouth, called *policies of credit*; it being ſuppoſed the aſſurer would enter them in his ledger: but of late, that benefit is become leſs frequent among traders, they have been made conſtantly in writing. For the hiſtory and practice of inſuring ſhips, ſee INSURANCE.

POLICY *of inſurance*, or *aſſurance of houſes*, is an inſtrument formed on the model of that for veſſels; whereby a perſon, or community of perſons, take on themſelves the riſks and damages that may befall houſes, their furniture, in whole, or in part, &c. from fire, on conſideration of a certain ſum, or ſums, to be paid by the aſſurer, according to the terms of the agreement.

The inſurance from fire is now a popular ſpecies of commerce; and we have a number of ſocieties erected into corporations for that purpoſe. See INSURANCE.

POLICY *of inſurance of lives*, is an inſtrument whereby a ſociety of perſons, erected into a corporation, &c. oblige themſelves to pay a certain ſum of money, e. gr. a hundred pounds, upon the death of a perſon whoſe life they aſſure, in conſideration of a ſum of money, e. gr. one guinea paid quarterly to the aſſurers, during the life of the ſaid perſon aſſured.

The *policy* is under the ſeal of the office, and entitles the perſon in whoſe favour it is granted, to make good his claim, according to the tenor of the articles, or by-laws, of the ſociety. See ASSURANCES *on lives*.

POLICY, *officers of*. See OFFICES.

POLICY, in *Letter Founding*, is ſometimes uſed for a rule that regulates the number of letters of each kind in a complete font; i. e. to determine how many, in proportion to the whole ſet, there are to be of each particular kind.

For inſtance, in a font of an hundred thouſand characters, there are to be five thouſand for *e*, a thouſand for *a*, three thouſand for *m*, thirty only for *k*, as many, or a little more, for *z*, *y*, and *w*; and in proportion for the other letters, the great and ſmall capitals, the initial letters, points, commas, double letters, &c. See *Letter* FOUNDERY.

POLIDE, formed of πολις, *city*, and denoting the patroneſs of a town or city, in *Mythology*, an epithet given to Minerva, under which title ſhe had two temples; one at Erythræa, in Achaia, and another at Tegea, in Arcadia.

POLIEA, Πολιεα, in *Antiquity*, a ſolemnity of Thebes in honour of Apollo, ſurnamed Πολιος, i. e. *grey*, becauſe he was repreſented in this city (contrary to the practice of all other places) with grey hairs. Potter.

POLIEUS, formed of πολις, *city*, and denoting the protector of a city, in *Mythology*, a name under which JUPITER had a temple in the citadel of Athens.

POLIIFOLIUM, in *Botany*, the name of a genus of plants deſcribed by Buxbaum, the characters of which are theſe: the flowers are monopetalous, of the bell-faſhioned globoſe kind; the ſeed-veſſel is divided into five parts, and contains a number of roundiſh ſeeds; the leaves are like thoſe of the poley-mountain, whence the name; the flowers reſemble thoſe of the arbutus, or ſtrawberry-tree; and the fruit that of the ciſtus.

The plant has been known among authors before, though ill named, and confounded with other genera; Ray has

called it *ſedum arbuti ſhore*. It properly belongs to the plants of the ſhrub-kind, with dry fruits, and ought to be placed after the chamærhododendron, in the regular arrangements of plants.

Beſide the common kind of this, there is an African one, the leaves of which are ſhorter and rounder than thoſe of this ſpecies, and which may be called the ſhort-leaved African ſhrub *poliſolium*. The *poliſolia* in the Linnæan ſyſtem are ſpecies of ANDROMEDA.

POLIOPTRUM, in *Optics*. See POLYOPTRON.

POLIOPUS, in *Ornithology*, a name given by Aldrovand, and ſome other authors, to the GRISETTA, a ſmall bird of the moor-hen kind.

POLISH *coins, meaſures*, &c. See COIN, MONEY, MEASURE, &c.

POLISHER, an inſtrument, called alſo a burniſher, uſed for poliſhing and burniſhing gold, ſilver, and other metals, when gilt or ſilvered; and matters of other kinds proper to take a poliſh.

The *poliſher* is different in the different arts and manufactories. The gilders uſe an iron *poliſher*, to prepare their metals before gilding; and the blood-ſtone, to give them the bright poliſh after gilding.

The *poliſher* uſed by the makers of ſpurs, bits, &c. is part iron, part ſteel, and part wood. The inſtrument conſiſts of an iron bar, with a wooden handle at one end, and a hook at the other, to faſten it to another piece of wood held in the vice, while the operator is at work. In the middle of the bow, withinſide, is what they properly call the *poliſher*; which is a triangular piece of ſteel, with a tail, whereby it is rivetted to the bow. What the cutlers call their *poliſhers* are a kind of wooden wheels, for grinding, made of walnut-tree, an inch thick, and of a diameter at pleaſure. They are turned by the great wheel; and it is on theſe they poliſh and ſmooth their works, with emery and putty.

The *poliſhers* uſed in the manufacture of glaſs are very different from all theſe. They conſiſt of two pieces of wood; the one flat, covered with old hat; the other long, and half round, is faſtened on the former, whoſe edge it exceeds, on both ſides, by ſome inches; which ſerve the workman to take hold of, and to work it backwards and forwards by.

The *poliſhers* uſed by ſpectacle makers are pieces of wood a foot long, ſeven or eight inches broad, and an inch and a half thick, covered with old caſtor-hat, whereon they poliſh the ſhell and horn-frames their ſpectacle glaſſes are to be fet in.

POLISHING, the art of giving a gloſs or luſtre to a thing; particularly a precious ſtone, marble, glaſs, a mirror, or the like.

POLISHING *of gimſets, ſimſes*, &c. ſucceeds the grinding thereof.

The *poliſhing* of a mirror is the laſt preparation given it, with emery or putty.

For an account of the methods recommended by various authors for *poliſhing* glaſs and metals in the conſtruction of teleſcopes, &c. ſee GRINDING.

For the *poliſhing* of diamonds, &c. ſee LAPIDARY.

POLISHING *copper plates*. See COPPER *plates*.

POLISHING *of ſhells*. See SHELLS.

POLISHING, *water*. See JAPANNING.

POLITICAL, πολιτικὸς, formed from πόλις, *city*, ſomething that relates to policy, or civil government.

In this ſenſe we ſay *political* intereſts, *political* views, *political* diſcourſes, &c.

POLITICAL *arithmetic* is the application of arithmetical calculations to *political* uſes and ſubjects; as the public revenues, number of people, extent and value of lands, taxes, trade, commerce, manufactures, or whatever relates to the power, ſtrength, riches, &c. of any nation or commonwealth; or, as Davenant conciſely defines it, the art of reaſoning by figures, upon things relating to government.

The chief authors who have attempted calculations of this kind are, Sir William Petty, Major Graunt, Dr. Halley, Dr. Davenant, and Mr. King; and the principal points ſettled by them are as follow.

According to Sir William Petty's computations, though the land of Holland and Zealand be not above 1,000,000 acres, nor that of France leſs than 8,000,000, yet the former are near a third part as rich and ſtrong as the latter. That the rents of lands in Holland are to thoſe in France, as 7 or 8 to 1. That the people of Amſterdam are two-thirds of thoſe of Paris or London; which, according to him, do not differ above a 20th part from one another. That the value of the ſhipping of Europe is about two millions of tons, whereof the Engliſh have 500,000, the Dutch 900,000, the French 100,000; the Hamburghers, Danes, Swedes, and Dantzickers, have 950,000; and Spain, Portugal, Italy, &c. about as much. That the value of goods then exported yearly from France into all parts, was quadruple of that exported into England alone; and conſequently, in all, about 5,000,000*l.* What was then exported out of Holland into England, was worth 300,000*l.* and what was exported thence into all the world, 18,000,000*l.* That the money yearly raiſed by the French king, in time of peace, is about 6½ millions ſterling; and that the monies raiſed in Holland and Zealand are about 24,000,000*l.* and in all the provinces together about 30,000,000*l.* That the people in England are about 6,000,000; and their expences, at 3*l.* per annum a head, 42,000,000*l.* or 800,000*l.* a week. That the rent of the lands is about eight millions, and the intereſts and profits of the perſonal eſtates as much. The rent of houſes in England 4,000,000*l.* That the profits of the labour of all the people is 26,000,000*l.* yearly. That in Ireland the people amount to about 1,200,000. That the corn ſpent in England, at 5*s.* the buſhel for wheat, and 2*s.* 6*d.* for barley, amounts to ten millions per annum. That the navy of England (then) required 36,000 men to man it, and other trade and ſhipping about 48,000. That in France, to manage the whole ſhipping trade, there were at that time required but 1500 men. That the whole people of France are about thirteen millions and a half; and thoſe of England, Scotland, and Ireland, together, about nine millions and a half. That, in the three kingdoms, are about 20,000 churchmen; and in France above 250,000. That in the dominions of England are above 40,000 ſeamen, and in France not above 12,000. That in England, Scotland, and Ireland, and all other dominions depending thereon, there was then about 60,000 tun of ſhipping, which is worth about four millions and a half in money. That the ſea-line round England, Scotland, and Ireland, and the adjacent iſles, is about 7,800 miles. That in the whole world are about three hundred and fifty millions of people; whereof thoſe with whom the Engliſh and Dutch have any commerce, are not above eighty millions. That the value of commodities annually traded for in the whole, is not above 45,000,000*l.* That the manufactures exported out of England amounted to about 5,000,000*l.* per annum. Lead, tin, and coals, to 500,000*l.* per annum. That the value of the French commodities (then) brought into England, did not exceed 1,200,000*l.* per annum. That the whole rath of England, in current money, was then about 6,000,000*l.* ſterling. See Sir W. Petty's *Political* Arithmetic, p. 74, &c.

Dr. Davenant gives ſome good reaſons why many of Sir Wm. Petty's numbers are not to be entirely depended upon; and, therefore, advances others of his own, founded on the obſervations of Mr. Greg. King.

Some of the particulars are, that the land of England is 39 millions of acres. That the number of people, according to his account, is about 5,500,000 ſouls, increaſing about 9000 every year, allowances being made for plagues, wars, ſhipping, and the plantations. The people in London he reckons at 530,000; thoſe in the other cities and market-towns in England, 870,000; and thoſe in the villages and hamlets, at 4,100,000. The yearly rent of the land he accounts to be 10,000,000*l.* That of the houſes and buildings 2,000,000*l.* per annum. The produce of all kinds of grain he reckons to be worth 9,075,000*l.* in a year moderately plentiful. The rent of the cornlands, annually, 2,200,000*l.* and their net produce above 9,000,000*l.* The rent of the paſture, meadows, woods, foreſts, commons, heaths, &c. 7,000,000*l.* The annual produce by cattle, in butter, cheeſe, and milk, he thinks is about 2,500,000*l.* The value of the wool yearly ſhorn, about 2,000,000*l.* Of horſes yearly bred, about 250,000*l.* Of the fleſh yearly ſpent as food, about 3,350,000*l.* Of the tallow and hides, about 600,000*l.* Of the hay yearly conſumed by horſes, about 1,300,000*l.* Of the hay conſumed by other cattle, 1,000,000*l.* Of the timber yearly felled for building, 500,000*l.* Of the wood yearly ſpent in firing, &c. about 500,000*l.* The land of England, to its inhabitants, is now about 7¼ acres per head. The value of the wheat, rye, and barley, neceſſary for the ſuſtenance of England, amounts to at leaſt 6,000,000*l.* ſterling, per annum. The value of the woollen manufacture made here is about 8,000,000*l.* per annum; and our exports of all kinds of the woollen manufacture amount to above 2,000,000*l.* per annum. The annual income of England, on which the whole people live and ſubſiſt, and out of which taxes of all kinds are paid, is ſtated at about 43,000,000*l.* that of France, 81,000,000*l.* and that of Holland, 18,250,000*l.* See Davenant's Eſſay upon the probable methods of making a people gainers in the balance of trade, &c. in his Works, vol. vi.

Major Graunt, in his obſervations on the bills of mortality, computes, that there are 39,000 ſquare miles of land in England. That in England and Wales there are 4,600,000 ſouls. That the people of London are about 640,000

640,000; being one fourteenth part of the people of England. That in England and Wales are about 10,000 parithes. That there are 25,000,000 of acres in England and Wales; viz. about four acres to every head. That but 64 out of 100 of the children born are living at 6 years old. That but 40 of 100 are alive at 16 years end. That but 25 of 100 at 26 years end. That but 16 at 36 years end. That but 10 out of 100 at 46 years end. That but 6 out of 100 at 56 years end. That but 3 out of 100 at 66 years end. And that but 1 out of 100 at 76 years end. And that London doubles itself in about 64 years.

Sir William Petty, in his difcourfe about duplicate proportion, farther tells us, that it is found by experience, that there are more perfons living between 26 and 26, than of any other age: and, laying down that as a fuppofition, he infers, that the fquare roots of every number of men's ages under 16 (whofe root is 4), fhew the proportion of the probability of fuch perfons reaching the age of 70 years.

Thus, it is 4 times more likely, that one of 16 years of age lives to be 70, than that a child of one year old does. It is thrice as probable, that one of 9 years lives to be 70, as that a new-born child does, &c. That the odds is 5 to 4, that one of 25 dies before one of 16 years. That it is 6 to 5 (ftill as the fquare roots of the ages) that one of 36 years old dies before one but of 25 years of age; and fo on, according to any declining age, to 70, compared with a number between 4 and 5, which is the root of 21, the law age.

Dr. Halley has made a very exact eftimate of the degrees of the mortality of mankind, from a curious table of the births and burials, at the city of Breflaw, the capital of Silefia; with an attempt to afcertain the price of annuities upon lives. From a table which he has calculated thence, publifhed in the Philofophical Tranfactions, he derives the following ufes.

1. To find in any multitude, or body, of people, the proportion of men able to bear arms; which he reckons from 18 to 56 years old, and accounts about $\frac{1}{4}$ of the whole. 2. To fhew the different degrees of mortality, or rather vitality, in all ages; by which means he finds the odds there is, that any perfon of any age doth not die in a year's time, or before he attains fuch an age. 3. To fhew in what number of years it is an even lay, that fuch a perfon fhall die; and finds, for inftance, that is an even lay, that a man of thirty years of age lives between twenty-feven and twenty-eight years. 4. To regulate the price of infurance upon lives. 5. And the valuation of annuities upon lives. 6. How to value two or three lives after the fame manner.

From the whole he makes two very good obfervations: 1. How juftly we ufe to complain of the fhortnefs of our lives; for that it appears, that one half of thofe that are born do not live above feventeen years.

2. That the growth and increafe of mankind is not fo much ftinted by any thing in the nature of the fpecies, as it is from the curious difficulty moft people make of venturing on the ftate of marriage; and, therefore, that celibacy ought to be every way difcouraged by all wife governments; and thofe who have numerous families of children ought to be countenanced and encouraged by good laws, fuch as the *jus trium liberorum*, &c. among the Romans.

According to Mr. Kerfeboom's computation, the inhabitants of Holland and Weft Friezeland, in the year 1738, amounted to 980,000. He has given us a table of the particulars, exhibiting the number of people of all ages, living at the fame time, from their birth to extreme old age. This table having the chances of mortality within the ages mentioned, he calls the table of contingency of life and death.

This table is calculated upon three principles. 1. On correct obfervations upon the tables of affignable annuities in Holland, which have been kept there for above 125 years; wherein the ages of the perfons dying are truly entered. 2. Upon a fuppofition that there are yearly born in the two provinces 28,000 living children. 3. That the whole number of inhabitants, in any country, is to the number of births as 35 to 1.

From this table it appears, 1. That more than half the number of people in the two provinces are above 27 years old. 2. That by the obfervations made in England, out of 35 children born, 18 of them are boys, and 17 girls: the inhabitants of Holland and Weft Friezeland confift of 504,000 males, and 476,000 females, the fum of which is 980,000.

Here follows the table of contingency of life and death.

Of above 90 years old		500
Of 90 to 86 incl.		2500
85	81	6500
80	76	13000
75	71	20300
70	66	27300
65	61	34300
60	56	40800
55	51	47000
50	46	53000
45	41	57800
40	36	62500
35	31	67600
30	27	58400
		491500 fum above 27 years old
Of 26	21	94300
20	16	83400
15	11	87200
10	6	91800
5 to birth		131800
		488500 fum under 27 years old
		491500
		488500
		980000 fum of all the inhabitants

Mr. Kerfeboom obferves, from the affignable annuities for lives before mentioned, that females, one with another, live about three or four years longer than the fame number of males.

He alfo thinks there is no reafon to differ from the proportions affigned by Mr. King (in Davenant's Eflays) of the ftate and condition of the inhabitants of England; which is, that for every 100,000 inhabitants there are,

Married men and women	34500
Widowers	1500
Widows	4500
Unmarried youth and children	45000
Servants	10500
Travellers, ftrangers, &c.	4000
	100000

If this propofition be admitted, then the number of each fort in Holland and Weft Friezeland, will be as in the following table:

In the two provinces of Holl. and Weft. Fr.		Amfter.
Married men and women	338100	86136
Widowers	14700	4218
Widows	44100	13858
Unmarried youth and children	441000	93990
Servants	102900	28718
Travellers, ftrangers, &c.	39200	12160
Total	980000	241000

The mortality of the feveral quarters of the year.

Spring to fummer	307 dead.
Summer to the autumnal equinox	286
Autumn to winter	287
Winter to fpring	286

The mortality of the different months of the year obferved for 31 years, one with another.

Dead in	
January	102
February	88
March	95
April	77
May	112
June	100
July	92
Auguft	95
September	99
October	93
November	95
December	99

Hence it appears, that April is the leaft, and May the moft fatal month in the year; their proportion of mortality being nearly as 2 to 3; and that of the four feafons of the year, moft deaths happen in the fpring; that is, from the vernal equinox to the fummer foltice.

Mr. Kerfeboom adds, that thefe provinces may raife

220,000 men able to bear arms, and several other curious observations.

His book is entitled, Verhandeling tot een proeve, om te weeten de probable Menigte des Volks in de Provincie van Holland en Westfriesland. Hague, 1738. 4to.

Dr. Brakenridge has given an estimate of the number of people in England, which he has formed from the number of houses and the quantity of bread consumed. According to the former principle, he states the number of houses throughout England and Wales at 911,310, and allows six persons, at an average, to a house, and thence computes the number of people to be about 6,257,418, or six millions, all ages included. From a survey of the window-lights, after the year 1750, the number of houses charged to that tax in England and Wales appears to have been 690,000; to which adding 200,000 cottages that pay nothing, the whole number appears to be 890,000; and the number of people, allowing six to a house, 5,340,000. Upon the latter principle, he estimates the number of quarters of wheat consumed at home to be 2,010,100; and allowing the quantity of a quarter for three persons in a year, or seven ounces a day for each person, he concludes, that the number of people is 6,978,300, or about six millions. Of this number, according to Dr. Halley's rule, he supposes that there may be about fifteen hundred thousand men able to carry arms. The country, he supposes, is capable of supporting one-half more inhabitants, or nine millions; for, admitting Mr. Templeman's survey, England contains 49,450 square miles, that is, 31,648,000 acres, of which 25,300,000 acres are proper to be cultivated; and allowing three acres, well manured, for the maintenance of one person, there will be maintenance in England for 8,430,000 people; to which the produce of fishing being added, it will enable the country to support nine millions. In Ireland, according to Mr. Templeman, there are 17,536,000 acres, of which, says Dr. Brakenridge, 12,000,000 are capable of cultivation; and allowing four acres, at an average, to each person, and the number of inhabitants to be (at much too low an estimate) one million, Ireland could maintain two millions more people than it has now. In Scotland, containing a million and a half of people, and 17,728,000 acres of land, of which the good acres are 11,000,000, allowing five acres for each person, he supposes there may be provision for 2,200,000 people, or for 700,000 more than there are at present. Hence he infers, that in both the British isles, properly cultivated, there is a provision for six millions of inhabitants beyond the number now supported in them. Extending his survey to the whole globe, he supposes the whole surface to be to the quantity of land as 8 to 3, i. e. as 197,810,550, to 74,181,331 square miles; out of which, deducting one-third for waste ground, there will be 49,454,887 square miles, or 31,651,129,680 good acres. And stating the whole number of inhabitants on the globe to be 4,000,000,000 there will be 79 good acres to each person. Phil. Transf. vols xlix. art. 45. art. 113.

For an account of the calculations of Dr. Price, a late well known and excellent writer on this subject, and farther particulars relating to the number of births and burials, the proportion of males and females, &c. see EXPECTATION *of life*, MARRIAGE, MORTALITY, &c.

POLITICAL *criticism*. See CRITICISM.

POLITICAL *liberty*. See LIBERTY.

POLITICS, *politice, μαστικη*, from πολις, *civitas, state*, the first part of œconomy, or ETHICS, consisting of the governing and regulating of states, for the maintenance of the public safety, order, tranquility, and good morals.

Lord Bacon divides *politics* into three parts, with regard to the three grand ends thereof, or the three offices incumbent on those who have the administration; viz. the *preservation* of the state; the *happiness* and *flourishing* of the state; and the *enlargement* of its bounds.

The two first parts, he observes, are well handled by several authors; but about the third there is a deep silence. He ranks this, therefore, among the number of the *deficienta*, and gives us a specimen of an essay to supply it.

We have several systems of *politics* by Aristotle, Machiavel, Doria, Lipsius, &c. in which last there is nothing but particles and conjunctions of the author's own; the body of the book being all quotations.

POLITICS, *academy of*. See ACADEMY.

POLITY, or POLICY. See POLICY.

POLIUM, *poley*, in *Botany*. See *Mountain* POLEY.

POLL, a term used in ancient writings for the head.

The word is, doubtless, formed from *pole*; this part being, as it were, the pole of the microcosm.

Hence, to *poll* is to enter down the names of persons who give their votes, or voices, at an election.

POLL, *deed*. See DEED.

POLLACK, in *Ichthyology*, a name which we give to two different fish of the asellus or gadus kind, with the different epithets of *rawe* and *whiting*. The *raw-pollack* is the same species that in some parts of England is called the cole-fish, and is the asellus niger of authors. The other is called the *whiting-pollack*, and is the *asellus ruffescens* of Willeghby and others; and the *gadus pollachius* of Linnæus.

Both these fishes are, according to the new Artedian system, of the genus of the gadi; and as the names taken from their colours, black and green, are very little expressive, the colours being not perfect, permanent, or entire, Artedi has devised others for them, by which they may be distinguished at sight from one another. The *raw-pollack*, or cole-fish, he distinguishes by the name of the *gadus* with three fins on the back, with no beard at the mouth, with the lower jaw longer than the upper, and the lateral line straight. The other, or *whiting-pollack*, he distinguishes by the name of the *gadus* with three fins on the back, with no beard, with the lower jaw longer than the upper, and the lateral line crooked. These two kinds of *pollack* are by these names not only distinguished from one another, but from all the other species of the same genus, as the cod-fish, &c.

The whiting *pollack* is common on many of our rocky coasts, and numbers of them are seen in summer sporting on the surface of the water, which are often taken with a goose's feather fixed to the hook. They do not grow to a large size, and are a good fish for the table.

POLLARD, among *Hunters*, a dag, or male deer, which has cast its horns.

POLLARD, or POLLENDER, in *Agriculture*, is applied to such trees as have been frequently polled, or lopped; by which they are contradistinguished from timber-trees.

POLLARD is a name given by some historians to a sort of base money current at one time in Ireland, and called more usually CROCARD.

These were coins of France, and other nations, which passed in Ireland as pennies, though really not worth quite half so much. They were made of copper, with a very small admixture of silver.

It was in the reign of Edward I. appointed lord of that kingdom in the life-time of his father Henry III. that the use of false and counterfeit money of this kind was so extremely common in Ireland. While his father reigned in England this prince never extended his power so far as to set up any mint, or coin any money in Ireland; but at his accession to the crown he found his treasury empty, and the current coin of his kingdoms in a very bad condition; his absence of near two years after his father's death having so encouraged the clippers and coiners of money, that little but clipped or counterfeit money of the kingdom was to be met with; and five or six different sorts of base and mixed money had been imported privately, and uttered in England and Ireland as pennies, though they were not half the value of the penny sterling.

These were the *crocards* and *pollards*, called also *mitres limmers, rosaries*, and by the like names, according to the things marked in the impressions. To remedy this evil, and restore the current coin of the kingdom to its ancient purity and value, this prince established a certain standard; and as the base money was an admixture of a very small quantity of silver, with a great deal of copper, he ordered that there should be in every pound of money weighing twelve ounces, eleven ounces and two penny weight and a quarter of pure silver, and only fourteen pence halfpenny farthing alloy.

The said pound to weigh twenty shillings and three pence in account; the ounce twenty pence, and the penny twenty-four grains and a half. According to this regulation, the money of Ireland was also ordered to be made, and a new kind of money was struck there in the year 1279, under Stephen de Fulbourn, bishop of Waterford, and lord deputy of Ireland. The pieces coined at this time in Ireland were groats, or four-pennies, halfpence, and farthings; and as these were the same in value, as to weight, with the English coins, they would go equally in England and Ireland; and in the twenty-ninth year of the reign of the same prince, that is, in 1300, the *crocards, pollards*, and other base money, were decried; and it was made death, with confiscation of goods, to import any of them.

By this means the circulation of the base and mixed money was in a great measure stopped, and four new furnaces were erected in the mint of Dublin, to supply the great demand that there was for good money; and Alexander Norman de Lime was appointed master of the coiners. This was a beginning of good money in Ireland; and in the year 1304, there were sent over from England twenty-four stamps for coining of money there, viz. three piles with six crosses, for pennies; three piles with six crosses, for halfpence; and two piles with four

troſſes, for farthings. In the old way of coining with the hammer, before the mill and ſcrew were invented; two kinds of punchions were in uſe, the one called the croſs, whereupon was engraved the head of the prince; and this was ſo called, becauſe anciently a croſs was the figure ſtruck on this ſide of coins inſtead of the head of the prince: the other, called the pile, contained the arms, or ſome other figure, to be ſtruck with an inſcription on the back, or reverſe of the coins. The pennies and halfpence ſtruck in this king's reign, have the king's head in a triangle full-faced. The beſt preſerved of them, found at this time, weigh twenty-two grains the penny; and the halfpence from ten grains to ten and a half. The farthings are ſo ſcarce, that it is very rare to meet with one in the collections of the moſt curious. Simon's Hiſt. of Iriſh Coins, p. 15.

POLLARD, in *Ichthyology*, a local name for the young and ſmall fiſh of the coie-fiſh, or *rawling*-POLLACK kind. It is uſed in Cornwall, &c.

POLLEN, in *Botany*. See FARINA *fecundans*.

POLLEN *thuris*, in the *Materia Medica*, a term uſed by the Latin writers to expreſs the *manna thuris*, or *manna libanotis*, of the Greeks, but that very improperly; for the word *pollen thuris* properly ſignifies the frankincenſe reduced to a powder; but this was not what the ancient Greeks called *manna thuris*, but the ſmall fragments which were broken off from the large pieces, in the gathering or packing up.

The *manna* uſed in medicine by the Greeks and Arabians was not formed into large flakes, as ours is; but was compoſed of ſmall fragments or grains, and therefore they called by the ſame name the ſmall granum or fragments alſo of other things: it was thus that the broken frankincenſe was called *manna thuris*.

This cuſtom of the times of ſaving all the fragments of this drug, made them collect even what was in ſo ſmall pieces as to reſemble powder; but this, though mixed with the reſt, was not properly the *manna thuris*. This gave occaſion to the adulterating this commodity, and Dioſcorides tells us, that even in his time they had learned the trick of putting the powder of the reſin of the pine tree among it; and this growing worſe and worſe, they at laſt diſcarded it, and would-purchaſe only the fragments without the powder. Theſe fragments they called *thus minutum*, to diſtinguiſh them from what was then called *manna thuris*, though improperly, and which was the adulterated maſs of reſin and fragments of olibanum.

POLLEX, in *Anatomy*, denotes either the thumb, or great toe, according as either manus, or pedis, is added to it.

POLLICIPES, the *toe-ſhell*, in *Natural Hiſtory*, the name of a genus of ſhells, the characters of which are theſe: they are multivalve flat ſhells, of a triangular figure, each being compoſed of ſeveral laminæ, which end in a ſharp point. They ſtand upon pedicles, and are furniſhed with a great number of hairs. We have only one known ſpecies of this genus, and this always found in large cluſters. *See Tab. of Shells*, N° 27.

POLLICIS *abductor*. See ABDUCTOR.

POLLICIS *adductor*. See ABDUCTOR.

Extenſor POLLICIS *brevis*, and *longus*. See EXTENSOR.

Flexor POLLICIS *brevis*, and *longus*. See FLEXOR.

POLLINCTORES, among the *Ancients*, an appellation given to thoſe who waſhed and anointed the dead.

POLLINCTURA, a word uſed by ſome authors to expreſs the embalming dead bodies.

POLLING, in *Gardening*, the operation of diſperſing the worm-caſts all over the walks, with long aſh-poles: this, beſides deſtroying worm-caſts, is very beneficial to the graſs of the walks. See GRASS-*walks*.

POLLUCTUM, among the Romans, a feaſt kept in honour of Jupiter Dapalis, Hercules, &c. at which ſacrifices were offered to the gods.

POLL-MONEY, or capitation, a tax impoſed by authority of parliament, on the perſon, or head, either on all indifferently, or according to ſome known mark of diſtinction; as quality, calling, &c.

Thus, by the ſtatute 18 Car. II. every ſubject in the kingdom was aſſeſſed by the *head*, or *poll*, according to his degree; every duke 100*l.* marquis 80*l.* baronet 30*l.* knight 20*l.* eſquire 10*l.* &c. and every ſingle private perſon 12*d.*

This was no new tax, as appears by former acts of parliament; particularly that anno 1380, where, *quilibet tam conjugatus quam ſolutus, utriuſque ſexus, pro capite ſuo ſolvere cogebatur*. Walſing.

Camden, in his Remains of Coins, ſays, there was anciently a perſonal tribute, called *capitatio*, or *poll-ſilver*, impoſed on the *poll*, or perſon, of every one; on women from the age of 12 years, and on men from 14.

POLLUTION, *pollutio*, the act of profaning a temple, or other holy place.

The Romaniſts hold a church to be polluted by the effuſion of blood, or of ſeed, therein; and require its being conſecrated anew.

The Jews were held polluted by the touching of a dead body, or of the menſes of women; and were to be purified in form. See the laws hereof in Leviticus.

The Indians are ſo ſuperſtitious on the head of *pollution*, that they break all the veſſels which thoſe of another religion have drank out of, or even only touched; and drain all the water out of a pond a ſtranger has bathed in.

POLLUTION, or *Self*-POLLUTION, is alſo uſed for the abuſing or defiling of one's own body, by means of laſcivious frictions and titillations, raiſed by art, to produce emiſſion.

We read in Scripture, that Onan, and, as ſome critics alſo think, Er, were ſeverely puniſhed for having polluted themſelves by ſpilling their ſeed on the ground; whence the crime has been denominated, by ſome, ONANIA.

Of *pollutions*, ſome are *voluntary*, others *involuntary*, and *nocturnal*.

POLLUTION, *pollutio nocturna*, in *Medicine*, the name of a diſeaſe, which conſiſts in an involuntary emiſſion of the ſeed in the night, in time of ſleep. This, in different perſons, is very different in degree; ſome being affected with it only once in a week, a fortnight, three weeks, or even a month, and others being ſubject to it almoſt every night.

The perſons moſt ſubject to this are young men of a ſanguineous temperament, and who feed high, and lead a ſedentary life. When this happens to a perſon but once in a fortnight, or a month, it is of no great conſequence; but when it happens almoſt every night, it greatly injures the health; the patients look pale and ſickly. In ſome the eyes become weak and inflamed; ſometimes they are affected with violent deflusions, and uſually, at laſt, are circled round with a livid appearance of the ſkin.

The diſtemper is to be cured rather by a change of life than by medicines. When it has taken its riſe from high diet and a ſedentary life, a coarſer food, and the uſe of exerciſe, will generally cure it; but if any medicines are to be given, nitre alone will do more than almoſt all the reſt. This may be taken in large doſes, a ſcruple at a time, with very little liquid with it, and muſt be continued for ſome time at night going to reſt. The root of the water-lily is greatly recommended by ſome in this caſe; and by others, the ſeeds of the agnus caſtus; but it is very doubtful, whether they have either of them any effect.

Perſons ſubject to this diſeaſe muſt never take any ſtimulating purges, and muſt avoid, as much as poſſible, all violent paſſions of the mind; and though exerciſe is recommended in moderation, yet if this be too violent, it will rather increaſe the diſorder than do any thing towards its cure.

The Romiſh church puts up prayers in the cloſe of the evening office, to be preſerved from nocturnal *pollutions*.

POLLUX, in *Aſtronomy*, the hind twin, or the poſterior part of the conſtellation GEMINI.

POLLUX is alſo a fixed ſtar of the ſecond magnitude, in the conſtellation GEMINI, or the Twins.

POLLUX is alſo uſed in *Mezzotinto*. See CASTOR.

POLLUX, in *Mythology*, the name of a demi-god, ſuppoſed to be the ſon of Jupiter and Leda, who had a temple in the city of Terapnæ, in Laconia, where was alſo a ſacred fountain, called Polydoces, or the fountain of *Pollux*.

POLPHOS, a word uſed by ſome authors to expreſs a bulb or bulbous root.

POLPOCH, in *Zoology*, a ſpecies of ſerpent ſaid to be found in Jucatan, a country bordering upon New Spain. It can bite with the mouth, and ſting with the tail.

POLTROON, or POLTROON, a coward, or daſtard, wanting courage to perform any thing great or noble.

The word we borrow from the French, who, according to Salmaſius, derive it *a pollice truncato*; becauſe, anciently, thoſe who would avoid going to the wars, cut off their thumbs.

But Menage, with more probability, derives it from the Italian *poltrone*, and that from *poltra*, a *bed*; becauſe timorous, puſillanimous people uſually take pleaſure in lying a-bed. He adds, that the Italian *poltra*, is again derived from the German *peltzer*, a *pillow*, or *cuſhion*.

Others chooſe to derive the word from the Italian *poltre*, *colt*; becauſe of that creature's readineſs to run away.

POLTROON, in *Falconry*, is a name given to a bird of prey when the nails and talons of his hind toes are cut off, wherein his chief force and armour lies; in order to intimidate him, and prevent his ſoaring at great game.

POLVERINE, the calcined aſhes of a plant; a ſubſtance of the nature of our pot-aſhes, or pearl-aſhes.

It is brought from the Levant and Syria; but in the glass trade, though it be of the nature of the other ashes they use, it is always to be preferred to any other. The barilla, or pot-ashes of Spain, yield more pure salt than the *polverine* of the Levant, but the glass made with it has always some tinge of bluishness: that made with the *polverine* is ever perfectly white, and this is the substance that ought always to be used for the finest crystal. See GLASS.

POLYACOUSTICS, compounded of πολυς, *much*, and ακουω, *I hear*, instruments contrived to multiply sounds; as multiplying-glasses, or polyscopes, do the images of objects. See PHONICS.

POLYADELPHIA, in *Botany*, the eighteenth class of plants, whose stamina are formed into three or more separate bodies, comprehending four orders, viz. *pentandria*, *dodecandria*, *icosandria*, and *polyandria*, having respectively, five, twelve, and twenty, and many in each set or body. See FRUCTIFICATION, and ORDER.

POLYANDRIA, in *Botany*, the thirteenth class of plants with hermaphrodite flowers, and a large number of stamina, or male parts, in each; comprehending seven orders, viz. *monogynia*, *digynia*, *trigynia*, *tetragynia*, *pentagynia*, *hexagynia*, and *polygynia*, distinguished by having one, and three styles. See FRUCTIFICATION, and ORDER.

POLYANTHEA, a collection of common-places in alphabetical order; of great service to orators, preachers, &c. of the lower class.

The word is formed from the Greek πολυς, *much*, and ανθος, *flower*; and is much of the same significancy with *anthology*, or *florilege*.

The first author of the *polyanthea* was Dominic Nanni de Mirabellio, whose labour has been improved on by Barth. Amantius, and Frans. Torsius; and since these, by Jos. Langius, under the title of *Polyanthea nova*, 1613.

POLYANTHEMUM, in *Botany*, a name given by some authors to the water-crowfoot, from its great number of flowers.

POLYANTHUS, or POLYANTHIUM, compounded of πολυς, *much*, and ανθος, *flower*, a garden flower, of the PRIMROSE kind. The word is also used, in general, to denote a plant which bears or produces several or many flowers.

POLYCARPON, in *Botany*, a genus of the *triandria trigynia* class: its characters are, that the calyx is five-leaved, the petals are five in number, small and ovated; and the fruit is a single-celled, three valved capsule. There is one species.

POLYCEPHALON, πολυκεφαλον, in *Antiquity*, a kind of pottery, for the nature and origin of which see Mem. de l'Acad. Roy. des Inscrip. vol. xiv.

POLYCOMBUS, in *Botany*, a name given by Neophytus and others to the common KNOT-*grass*, more usually called *polygonum*.

The name *polycombus* is formed of the Greek πολυς, *many*, and κωμος, *a joint*; and as it is usually applicable to this, and all the other jointed plants, it is used by some for the name of the several species of equisetum, or horsetail, as the word *polygonum* is.

Neophytus describes one species of this, which he says is called *ereon*, from its growing in mountainous places. This, he says, looks like a young reed, and has several joints in the main stalk, which are received into one another as to many cups or boxes: he adds, that the leaves are like those of the pine-tree. What he calls the leaves, are probably the tender branches; and then this description will agree very well with our great marsh horsetail, which grows in wet places in mountainous countries, and about the springs in our hills. This is the horsetail to which the greatest virtues are attributed by this author; but the whole account of the hippuris, polygonum, and equisetum, is so confused, that there is little to be learnt from what the ancients say of them, without repeating the trials of their virtues.

POLYCHREST, πολυχρηστος, compounded of πολυς, *much*, and χρηστος, *useful*, in *Pharmacy*, a medicine that serves for many uses, or that cures many diseases.

POLYCHRESTY, *sal*. See SAL-*Polychrest*.

POLYENEMUM, in *Botany*, a genus of the *triandria monogynia* class: its characters are, that the calyx is three-leaved; the petals are five, and calciform; and the fruit contains a single seed almost naked. There is one species.

POLYCROTA, in the *Naval Architecture of the Ancients*, a word used to express such of their gallies as had three, four, five, or more tiers of rowers, seated at different heights; they were distinguished by this term from the *monocrotæ*, or those which had only single rows of oars. The number of rows of rowers in the *polycrotæ* gallies has given occasion to some to suppose those vessels of such a height from the water as is scarce credible; we have, however, no warrant for this, but the commentators have given occasion to the opinion, from their not having been able to stow the rowers in less room, and have measured the height of the vessel by their own skill in this sort of architecture, not by that of the people who built them. Meibomius has found a way to take off a great deal from the imaginary height of these gallies. He has two inventions to answer this purpose: by the first of them, he shews how the lateral rowers may be so placed, that he who sits behind another may move his hands and oar under the seat of the rower who sits next before him; by which means three lateral rowers, which, according to Scaliger's way of reckoning, would require thirteen feet and a half, will be placed in the height of seven feet and a half.

By the second invention, he finds out a place in the vessel for almost half the number of rowers; forasmuch as on the sides of the aforesaid rowers, he places others in the middle of the ship, upon transtra or transverse seats, which he imagines thrust out their oars under the seats of the lateral rowers; by this contrivance he has gained no less than nine feet in the height of a quinquiremis. The different series of rowers were called by different names; the *thalamiæ* were those who sat in the lowest row; the *zygia* were those who sat in the *transtra*, or cross seats; and the *thranitæ* those who sat uppermost of all in the vessel.

The most surprising account of a *polycrot* vessel among the ancients, is that said to have been built by Philopater, of forty tiers of rowers. The next to this is that of Ptolemy Philadelphus, which is said to have had thirty tiers; and in these there sat more than three thousand rowers. It has been disputed by many, whether such immense vessels as these were ever built, or ever could be used, if built. The monstrous height they have been calculated to be of, according to the schemes of the generality of commentators, has rendered it incredible that there were ever any such; but Meibomius has found out such convenient ways of placing the rowers in them, and has taken off so great a part of this imaginary height necessary in them, that he is clearly of opinion, that there were such vessels actually built and used.

The triremis, according to the computation of this author, contained two hundred men; of which one hundred and eighty were rowers, and the rest were mariners: so that the Athenian fleet, of which Conon was commander, consisting of one hundred and eighty triremes, had in it six and thirty thousand men. The quinquiremis of these times contained four hundred and twenty men, three hundred of whom were rowers, and the rest soldiers; so that there are three stupendous things to be observed in regard to the Roman fleet at Messina and the Carthaginian at Lilybæum: one is, that the former consisted of three hundred and thirty and the latter of three hundred and fifty vessels, most of which were quinqueremes, which, according to the most accurate computation, were a hundred and fifty feet long; the number of men they contained was, in the Roman, one hundred and thirty thousand, and, in the Carthaginian, one hundred and fifty thousand. The apparatus and provisions necessary for such a numerous host, are wonderful in these early days of shipping, and the accounts would be doubted, were they not given by one of the best of historians, Polybius, who wonders, as indeed he very well may, at such an amazing equipage for its service at such a time.

POLYEDRON. See POLYHEDRON.

POLYEIDÆ *lapides*, the name of a sort of troches or pastils greatly used among the ancients. They consisted of storax, four drachms; myrrh and aloes, of each five drachms; pomegranate-peel, and bull's gall, of each six drachms: all which were rubbed to fine powder, and made into troches with the bull's gall, mixed with a sufficient quantity of the most austere wine.

POLYGALA, *milkwort*, in *Botany*. See MILK-*wort*.

POLYGAMIA, in *Botany*, the twenty-third class of plants, comprehending three orders, viz. *monoecia*, or such plants as have the polygamy on the same plant, *dioecia*, having the polygamy on two distinct plants, and *trioecia*, having the polygamy on three distinct plants. See FRUCTIFICATION and ORDER.

POLYGAMY, Πολυγαμια, formed from πολυς, *multus*; and γαμος, *vir*, *wife*; a plurality of wives, or husbands, held by the same man, or woman, at the same time.

Polygamy is prohibited among Christians; but it was allowed among the Jews; as it is still among the Mahometans; and under all the religions that have obtained in Asia. In the kingdoms of Boutan and Thibet, *polygamy* is at this time almost general; one wife frequently serving all the males of a whole family, without being the cause of any uncommon dissensions or jealousy among them. Major Grauat observes, that themales and females brought into the world are nearly on a balance, only abating for a little excess on the side of the males, to make up for the

extraordinary

extraordinary expence thereof in war, and at sea: whence it evidently follows, that nature only intends one wife, or one husband, for the same person; since, if they have more, some others must go without any at all. See MARRIAGE.

Hence he concludes, that the Christian law, which prohibits *polygamy*, is more agreeable to the law of nature than the Mahometan's and we may add, than the Jewish law, which tolerated *polygamy*.

Dr. Percival, Phil. Trans. vol. lxvi. part i. p. 165, has very justly observed, that the practice is brutal, destructive to friendship and moral sentiment, inconsistent with one great end of marriage, the education of children, and subverting of the natural rights of more than half of the species besides, it is injurious to population, and, therefore, can never be countenanced or allowed in a well regulated state; for, though the number of females in the world may considerably exceed the number of males, yet there are more men capable of propagating their species than women capable of bearing children; and it is a well known fact, that Armenia, in which a plurality of wives is not allowed, abounds more with inhabitants than any other province of the Turkish empire.

Yet Selden has proved, in his Uxor Hebraica, that plurality of wives was allowed of, not only among the Hebrews, but also among all other nations, and in all ages. It is true, the ancient Romans were more severe in their morals, and never practised it, though it was not forbid among them: and Mark Antony is mentioned as the first who took the liberty of having two wives.

From that time it became pretty frequent in the empire, till the reigns of Theodosius, Honorius, and Arcadius, who first prohibited it by express law in 393. After this the emperor Valentinian, by an edict, permitted all the subjects of the empire, if they pleased, to marry several wives: nor does it appear, from the ecclesiastical history of those times, that the bishops made any opposition to this introduction of *polygamy*. In effect, there are some even among the Christian casuists, who do not look on *polygamy* as in itself criminal. Junius observes, that the prohibition of *polygamy* is a positive law; but from which a man may be exempted by sovereign necessity. Baillet adds, that the example of the patriarchs is a very powerful argument in favour of *polygamy*.

It has been much disputed among the doctors of the civil law, whether *polygamy* be adultery. In the Roman law it is called STUPRUM, and punished as such, that is, in some cases, capitally. But a smaller punishment is more consistent with the Jewish law, wherein the prohibition of adultery is perpetual, but that of *polygamy* temporary only. See Selden, lib. i. cap. 9. de Uxore Hebraica.

In Germany, Holland, and Spain, this offence is differently punished. By a constitution of Charles V. it was a capital crime. By the laws of ancient and modern Sweden, it is punished with death. In Scotland it is punished as perjury.

In England it is enacted by statute 1 Jac. I. cap. 11. that, if any person, being married, do afterwards marry again, the former husband or wife being alive, it is felony, but within the benefit of clergy. The first wife in this case shall not be admitted as an evidence against her husband, because she is in the true wife; but the second may, for she is indeed no wife at all; and so *vice versâ*, of a second husband. This act makes an exception to five cases, in which such second marriage, though in the three first is void, is, however, no felony. 1. Where either party hath been continually abroad for seven years, whether the party in England had notice of the other's being living or no. 2. Where either of the parties hath been absent from the other seven years, within this kingdom, and the remaining party hath had no notice of the other's being alive within that time. 3. Where there is a divorce or separation *a mensâ et thoro* by sentence in the ecclesiastical court. 4. Where the first marriage is declared absolutely void by any such sentence, and the parties loosed *a vinculo*. Or, 5. Where either of the parties was under the age of consent at the time of the first marriage; for in such case the first marriage was voidable by the disagreement of either party, which this second marriage very clearly amounts to. But if at the age of consent the parties had agreed to the marriage, which completes the contract, and is, indeed, the real marriage, and afterwards one of them should marry again, judge Blackstone apprehends that such second marriage would be within the reason and penalties of the act. Comment. book iv. p. 164.

Bernardus Ochinus, general of the order of Capuchins, and afterwards a protestant, published about the middle of the sixteenth century, Dialogues in favour of *polygamy*, which were answered by Theodore Beza. And about the conclusion of the last century we had at London an artful treatise published in behalf of a plurality of wives, under the title of Polygamia Triumphatrix: the author whereof assumes the name of Theophilus Alethens; but his true name was Lyserus: he was a native of Saxony. It has been answered by several.

In the year 1780, the rev. Mr. Madan published a treatise, artfully vindicating and strongly recommending *polygamy*, under the title of Thelyphthora; or a Treatise on Female Ruin, in its Causes, Effects, Consequences, Prevention, and Remedy, &c. Marriage, according to this writer, simply and wholly consists in the act of personal union, or *actus carnis*. Adultery, he says, is never used in the sacred writings but to denote the defilement of a betrothed or married woman, and to this sense he restricts the use of the term; so that a married man, in his opinion, is no adulterer, if his commerce with the sex be confined to single women, who are under no obligations by espousals or marriage to other men: but, on the other hand, the woman who should dare to have even but once an intrigue with any other man besides her husband, (let him have as many wives as Solomon), would, *ipso facto*, be an adulteress, and ought, together with her gallant, to be punished with immediate death. This, he boldly says, is the law of God: and on this foundation he limits the privilege of *polygamy* to the man; in support of which he refers to the polygamous connections of the patriarchs and saints of the Old Testament, and infers the lawfulness of their practice from the blessings which attended it, and the laws which were instituted to regulate and superintend it. He contends for the lawfulness of Christians having, like the ancient Jews, more wives than one; and labours much to reconcile the genius of the evangelical dispensation to an arrangement of this sort. With this view he asserts, that there is not one text in the New Testament that even hints at the criminality of a polygamous connection; and he would infer from St. Paul's direction, that bishops and deacons should have but one wife, that it was lawful for laymen to have more. Christ, he says, was not the giver of a new law; but the business of marriage, *polygamy*, &c. had been settled before his appearance in the world, by an authority which could not be revoked. Besides, this writer not only thinks *polygamy* lawful in a religious, but advantageous in a civil light, and highly politic in a domestic view.

In defence of his notion of marriage, which, according to his account of it, consists in the union of man and woman as one body, the effects of which in the sight of God no outward forms or ceremonies of man's invention can add to or detract from, he grounds his principal argument on the Hebrew words made use of in Gen. ii. 24. to express the primitive institution of marriage, viz. דבק באשתו rendered by the LXX προσκολληθήσεται πρὸς τὴν γυναῖκα αὐτοῦ, which translation is adopted by the evangelist (Matt. xix. 5.) with the omission only of the superfluous preposition (πρὸς) after the verb. Our translation he says—"shall cleave to his wife" doth not convey the idea of the Hebrew, which is literally, as Montanus renders the words, "shall be joined or cemented *in* his woman, and they shall become (i. e. by this union) one flesh." But on this criticism, it is well remarked, that both the Hebrew and Greek terms mean simply and literally attachment or adherence; and are evidently made use of in the sacred writings to express the whole scope of conjugal fidelity and duty, though he would restrain them to the grossest part of it. See Deut. ix. 4. Joshua xxiii. 8. *Acts* v. 36.

With respect to the Mosaic law, for which Mr. Madan is a warm advocate, it was certainly a local and temporary institution, adapted to the ends for which it was appointed, and admirably calculated, in its relation to marriage, to maintain and perpetuate the separation of the Jewish people from the Gentiles. In attempting to depreciate the outward forms of marriage, this writer would make his readers believe, that because none are explicitly described, therefore none existed: and, consequently, that they are the superfluous ordinances of human policy. But it is evident, from comparing Ruth iv. 10, 13. with Tobit vii. 13, 14. and from the case of Dinah, related Gen. ch. xxxiv. that some forms were deemed essential to an honourable alliance by the patriarchs and saints under the Old Testament, exclusive of the carnal knowledge of each other's persons. It is also evident in the case of the woman of Samaria, whose connection with a man not her husband, is mentioned in John iv. that something besides cohabitation is necessary to constitute marriage in the sight of God.

Having stated his notion of marriage, he urges, in defence of *polygamy*, that notwithstanding the seventh commandment, it was allowed by God himself, who made laws for the regulation of it, wrought miracles in support of it by making the barren woman fruitful, and declared the issue legitimate to all intents and purposes. God's allowance of *polygamy* is argued from Exod. xxi. 10. and particularly from Deut. xxi. 15. which, he says, amounts to a demonstration. This passage, however, at the utmost, only

presupposes that the practice might have existence among so hard-hearted and fickle a people as the Jews; and therefore wisely provides against some of its more unjust and pernicious consequences; such as tended to affect the rights and privileges of heirship. Laws enacted to regulate it cannot be fairly urged in proof of its lawfulness on the author's own hypothesis; because laws were also made to regulate divorce, which Mr. Madan condemns as absolutely unlawful, except in cases of adultery. Besides, it is more probable, that the "hated wife" had been divorced by a bill of divorcement, than that she was retained by her husband: and moreover, it is not certain that the two wives, so far from living with the same husband at the same time, might not be dead: for the words may be rendered thus "if there *should have been* to a man two wives, &c." The words expressing the original institution of marriage, Gen. ii. 24. compared with Matt. xix. 4, 5, 8. afford insuperable objections against Mr. Madan's doctrine of *polygamy*. See also Lev. xviii. 18. 1 Cor. vii. 2, &c.

If we appeal on this subject, from the authority of scripture to the writings of some of the earliest fathers in the Christian church, there is not to be found the faintest trace of any thing resembling a testimony to the lawfulness of *polygamy*: on the contrary, many passages occur, in which the practice of it is strongly and explicitly condemned. See Justin Martyr's Dial. with Trypho the Jew, Greek edit. by Thrirby, fol. p. 330, 423, 372. Clemens Alexandrin. Stromat. lib. iv. p. 312, 335, 336. edit. Heinsii, &c. Log. Bat. fol. 1616.

We shall close this article with the words of an excellent anonymous writer, to whose critique on Mr. Madan's work we are indebted for the above remarks: "in a word, when we *reflect*, that the primitive institution of marriage limited it to one man and one woman; that this institution was adhered to by Noah and his sons, amidst the degeneracy of the age in which they lived, and in spite of the example of *polygamy*, which the accursed race of Cain had introduced; when we consider how very few, (comparatively speaking) the examples of this practice were among the faithful; how much it brought its own punishment with it; and how dubious and equivocal those passages are in which it appears to have the sanction of divine approbation; when to these reflections we add another, respecting the limited views and temporary nature of the more ancient dispensations and institutions of religion—how often the imperfections, and even vices of the patriarchs, and people of God, in old time, are recorded, without any express notification of their criminality—how much is said to be commanded, which our reverence for the holiness of God and his law, will only suffer us to suppose, were, for wise ends, permitted—how frequently the messengers of God adapted themselves to the genius of the people to whom they were sent, and the circumstances of the times in which they lived;—above all, when we consider the purity, equity, and benevolence of the Christian law; the explicit declarations of our Lord, and his apostle St. Paul, respecting the institution of marriage, its design and limitation;—when we reflect too, on the testimony of the most ancient fathers, who could not possibly be ignorant of the general and common practice of the apostolic church; and, finally, when to these considerations we add those which are founded on justice to the female sex, and all the regulations of domestic economy and national policy, we must wholly condemn the revival of *polygamy*; and thus bear our honest testimony against the leading design of this dangerous and ill-advised publication." Monthly Review, vol. xliii. p. 338.

POLYGAMY is also used in the *Canon Law*, for a plurality of wives, though only had successively, or one at a time; in the Romish church this disqualifies a man for the episcopate. See BIGAMY.

POLYGLOTT, *Hexaglottum*, thus called from πολυς, and γλωττα, *tongue*, *language*, among *Divines* and *Critics*, chiefly denotes a Bible printed in several languages.

The first *Polyglott* Bible is that of cardinal Ximenes, printed in 1515, at Alcala de Henares; and commonly called the *Bible of Complutum*, or the *Complutensian Bible*; and contained in six volumes.

It contains the Hebrew text, the Chaldee paraphrase on the Pentateuch, the Greek version of the LXX. and the ancient Latin version.

In this *Polyglott* there is no other Latin version from the Hebrew, besides this last; but there is added another literal one from the Greek Septuagint. The Greek text of the New Testament is here printed, without accents, to bring it nearer to the original of the apostles, or, at least, to the most ancient copies; wherein there are no accents found.

At the end is added an apparatus of grammars, dictionaries, and indices, or tables. The chief author, Ximenes de Cisneros, cardinal, and archbishop of Toledo, in his dedication to pope Leo X. observes, that it was necessary to give the holy Scriptures in their originals, there being no translation, how good soever, that can render them perfectly.

The second *Polyglott*, called the *Bible regia*, is that of Philip II. printed by Plantin, at Antwerp, in 1571, in eight volumes, with a better paper and letter than the former, and the care of the edition imposed on Arias Montanus.

In this, besides every thing in the Bible of Complutum, there are added, the Chaldee paraphrases on the rest of the Old Testament, besides the Pentateuch, with a Latin translation of those paraphrases. In this *Polyglott* is likewise a very literal Latin version of the Hebrew text; for the use of those who have a mind to learn the Hebrew language.

As to the New Testament, beside the Greek and Latin of the Bible of Alcala, in this edition there is added an ancient Syriac version, both in Syriac and Hebrew characters, with points, to facilitate the reading thereof to those accustomed to read Hebrew. To the Syriac is likewise added a Latin one, composed by Guy le Fevre, who had the care of the Syriac version of the New Testament.

Lastly, in the *Polyglott* of Antwerp, is added a more copious apparatus of grammars, dictionaries, &c. than in that of Complutum; with several little treatises, judged necessary for clearing up the more difficult passages in the text.

The third *Polyglott* is that of M. le Jay, printed at Paris in 1645, in ten volumes, which has this advantage over that of Philip II. that it has the Syriac and Arabic versions of the Old Testament, with Latin interpretations. In the Pentateuch it has likewise the Hebrew and Samaritan text; and the Samaritan version in Samaritan characters.

As to the New Testament, beside every thing in the *Polyglott* of Antwerp, here is added an Arabic translation, with a Latin interpretation. But here are wanting the apparatus, and the grammars and dictionaries, which are both in the former *Polyglotts*; which renders this great work very imperfect.

The fourth *Polyglott* is that of London, printed in 1657, in six volumes, called Walton's *Polyglott*, from the author of the edition, Dr. Brian Walton, afterwards bishop of Winchester.

This is, indeed, less magnificent than that of M. le Jay, with regard both to the size of the paper, and the beauty of the characters; but is, in all other respects, preferable; being both much more ample and more commodious.

In this the Vulgate is printed according to the revised and corrected edition of Clement VIII. which is not done in that of Paris, where the Vulgate is printed as it stands in that of Antwerp, before that correction.

This likewise contains an interlineary Latin version of the Hebrew text; whereas the Paris edition has no other Latin version from the Hebrew beside the common Vulgate: again, the Greek Septuagint printed in the *Polyglott*, is not the same with that printed in the Bible of Complutum, which was retained in the editions of Antwerp and Paris, but the Greek text of the edition of Rome. To which are added the various readings of another very ancient Greek copy, called the *Alexandrian*, because brought from Alexandria.

The Latin version of the Greek of the Septuagint, is that published by Flaminius Nobilius, by authority of pope Sixtus V. Add, that in this *Polyglott* are found some parts of the Bible in the Ethiopic and Persian; nothing whereof appears in any of the rest.

Lastly, this edition has the advantage of preliminary discourses, called *prolegomena*, on the texts, both of the originals and versions; with a volume of various readings of all the different editions.

Dr. Edmund Castell, Arabic professor at Cambridge, in 1669, published a Lexicon Heptaglotton, for the use of Walton's *Polyglott*, in two volumes, folio. See the Preface to this *Polyglott*.

To the number of the *Polyglotts* may likewise be added, the two Pentateuchs, printed by the Jews of Constantinople, in four languages; but all in Hebrew characters. In one of these Pentateuchs, printed in 1553, is found the Hebrew text, in large characters; on one side, wherein is the Chaldee paraphrase of Onkelos, in middling characters; and, on the other side, a paraphrase in the Persian, composed by a Jew, one Jacob de Tous, so called from the city where he lived. Beside these three columns, the Arabic paraphrase of Saadias Gaon is printed in small characters, at the top of the page; and at bottom is added the commentary of Rasch.

The other *Polyglott* was printed at Constantinople in 1547, in

in three columns like the former. The Hebrew text of the law is in the middle, a translation into the vulgar Greek on one side, and a Spanish translation on the other. These versions are both in Hebrew characters, with points to determine the pronunciation. At the top of the page is added the Chaldee paraphraſe of Onkelos, and at the bottom the commentaries of Raſchi.

To all theſe may be added, as a ſeventh *Polyglott*, the Pſalter publiſhed by Aug. Juſtinian, a Dominican, and biſhop of Nebio, at Genoa, 1516, containing the Hebrew, Greek, Arabic, and Chaldee, with Latin interpretations, and gloſſes.

There are alſo various other editions of the Bible, either in whole, or in part, which might be ranged under the article of *Polyglotta*; though they are not ſo denominated. Such are the *Hexapla*, and *Octapla*, of Origen.

And the Bible of Hutter, printed at Hamburgh in Hebrew, Chaldee, Greek, Latin, German, Saxon, Italian, French, Sclavonic, Daniſh, &c.

POLYGLOTTA *avis*, in *Ornithology*, the name of a bird deſcribed by Nieremberg, and which he ſays, he ſaw and heard, with admiration, ſinging in all tones. It is of the ſize of our ſtarling.

Its back is brown, and its breaſt and belly white; and near the neck and tail it is variegated with ſpots and ſtreaks of white; its head has a ſtreak of white, which repreſents a ſort of crown of ſilver; it is mightily eſteemed, and kept in cages by the Spaniards, as infinitely ſuperior to all other birds in melody; it feeds on almoſt any thing that is given it, and is moſt fond of the warmer climates; but endures the more temperate ones without harm. Ray.

The polyglotta of Linnæus is a ſpecies of the TURDUS. See MOCK-*bird*.

POLYGON, Πολυγωνος, formed from πολυς, *many*, and γωνια, *angle*, in Geometry, a multilateral figure, or a figure whoſe perimeter conſiſts of more than four ſides and angles.

If the ſides and angles be equal, the figure is called a *regular polygon*. For *ſimilar polygons*, ſee SIMILAR.

Polygons are diſtinguiſhed according to the number of their ſides. Thoſe of five ſides are called *pentagons*; thoſe of ſix, *hexagons*; thoſe of ſeven, *heptagons*; thoſe of eight, *octagons*, &c. The particular properties, &c. of each whereof, ſee under its proper article, PENTAGON, HEXAGON, &c.

POLYGONS, *general properties of*. Euclid demonſtrates theſe which follow: 1. That every *polygon* may be divided into as many triangles as it hath ſides.

This is done by aſſuming a point, as F (*Tab. Geom. fig.* 8.) any where within the *polygon*, and thence drawing lines to every angle, F *a*, F *b*, F *c*, F *d*, &c.

2. The angles of any *polygon*, taken together, make twice as many right ones, abating four, as the figure hath ſides. Thus, if the *polygon* hath five ſides, the double of that is 10; whence ſubtracting 4, there remains 6 right ones.

3. Every *polygon*, circumſcribed about a circle, is equal to a rectangled triangle, one of whoſe legs is the radius of the circle, and the other the perimeter or ſum of all the ſides of the *polygon*.

Hence, every regular *polygon* is equal to a rectangled triangle, one of whoſe legs is the perimeter of the *polygon*; and the other, a perpendicular drawn from the centre to one of the ſides of the *polygon*.

Hence alſo, every *polygon*, circumſcribed about a circle, is bigger than it; and every *polygon*, inſcribed, is leſs than the circle. The ſame, likewiſe, appears hence, that the thing containing is ever greater than the thing contained. Hence, again, the perimeter of every *polygon*, circumſcribed about a circle, is greater than the circumference of that circle; and the perimeter of every *polygon* inſcribed, leſs: whence it follows, that a circle is equal to a right-angled triangle, whoſe baſe is the circumference of the circle, and its height the radius; ſince this triangle is leſs than any *polygon* circumſcribed, and greater than any inſcribed.

Nothing, therefore, is wanting to the quadrature of the circle, but to find a right line equal to the circumference of a circle.

POLYGON, *to find the area of a regular*. Multiply a ſide of the *polygon*, as A D, by half the number of the ſides, e. gr. the ſide of a pentagon by 2½. Again, multiply the product by a perpendicular let fall from the centre of the circumſcribing circle to the ſide A B; the product is the area required.

Thus, ſuppoſe A B 343 and half the number of ſides 2½; the product of ſemiperimeter is 1715. Suppoſing then the perpendicular F H 491; the product of theſe two 8015, is the area of the pentagon required.

POLYGON, *to find the area of an irregular*, or *trapezium*. Reſolve it into triangles; find the ſeveral areas of the ſeveral triangles, ſee TRIANGLE. The ſum of theſe is the area of the *polygon* required.

POLYGON, *to find the ſum of all the angles in any*. Multiply the number of ſides by 180°: from the product ſubtract 360; the remainder is the ſum required.

Thus in a pentagon, 180, being multiplied by 5, gives 900; whence ſubtracting 360, there remain 540; the ſum of the angles of a pentagon.

Hence, if the ſum found, be divided by the number of ſides, the quotient will be the angle of a regular *polygon*.

Or, the ſum of the angles is more ſpeedily found thus: multiply 180 by a number leſs by two than the number of ſides of the *polygon*: the product is the quantity of the angles required: thus, in a pentagon, 180 being multiplied by 3, a number leſs by two than that of its ſides, the product is 540, the quantity of angles as before.

The following table exhibits the ſums of the angles in all rectilineal figures, from a triangle to a dodecagon; and is of good uſe both for the deſcribing of regular figures, and for proving, whether or no the quantity of angles have been truly taken with an inſtrument.

Num. Sides.	Sum. Ang.	Ang. of Reg. fig.	Ang. at the centre	Num. Sides.	Sum. Ang.	Ang. of Reg. fig.	Ang. at the centre
III.	180°	60°	120°	VIII.	1080°	135°	45°
IV.	360	90	90	IX.	1260	140	40
V.	540	108	72	X.	1440	144	36
VI.	720	120	60	XI.	1620	147 16′ 22″	32 43′ 38″
VII.	900	128 34′ 51″	51 25′ 43″	XII.	1800	150	30

This table is formed by dividing 360, the degrees in a circumference, by the number of the ſides in each *polygon*; and the quotients are the angles at the centres; the angle at the centre ſubtracted from 180° leaves the angle at the circumference; and the ſum of the angles is had by doubling the number of ſides, ſubtracting 4 from the product, and multiplying the remainder by 90.

POLYGON, *to inſcribe a regular, in a circle*. Divide 360 by the number of ſides in the *polygon* required, to find the quantity of the angle E F D. Set off the angle at the centre, and apply the chord thereof, E D, to the periphery, as often as it will go. Thus will the *polygon* be inſcribed in the circle.

The reſolution of this problem, though it be mechanical, yet is not to be deſpiſed, becauſe both eaſy and univerſal. Euclid, indeed, gives us the conſtruction of the pentagon, decagon, and quindecagon; and other authors give us thoſe of the heptagon, enneagon, and hendecagon; but they are far from geometrical *ſtrictneſs*.

Renaldinus lays down a catholic rule for the deſcribing of all *polygons*, which many other geometricians have borrowed from him; but Wagnerus and Wolfius have both demonſtrated the falſity thereof.

POLYGON, *about a regular, to circumſcribe a circle*; or, *to circumſcribe a regular* POLYGON *about a circle*. Biſect two of the angles of the given *polygon* A and E, by the right lines A F and E F, concurring in F; and from the point of concourſe with the radius E F deſcribe a circle.

To circumſcribe a *polygon*, &c. divide 360 by the number of ſides required, to find F *a*; which ſet off from the centre F, and draw the line *a d*; on this conſtruct the *polygon*, as in the following problem. See CIRCUMSCRIBING.

POLYGON, *on a given line* E D *to deſcribe any given regular*. Find an angle of the *polygon* in the table; and in E let off an angle equal to it, drawing E A = E D. Through the three points, A E D, deſcribe a circle. In this apply the given right line as often as it will go. Thus will the required figure be deſcribed.

POLYGON, *to inſcribe to circumſcribe a regular, trigonometrically*. Find the ſine of the arc produced by dividing the ſemiperiphery 180 by the number of ſides of the *polygon*: the double of this is the chord of the double arc; and therefore the ſide A E to be inſcribed in the circle. If then the radius of a circle, wherein, e. gr. a pentagon is to be inſcribed, be given in any certain meaſure, e. gr. 345, the ſide of the pentagon is found in the ſame meaſure by the rule of three thus: as radius 1000 is to 1176 ſo is 3450 to 4057, the ſide of the pentagon. With the given radius, therefore, deſcribe a circle; and therein ſet off the ſide of the *polygon* as often as it will go: thus will a *polygon* be inſcribed in the circle.

To ſave the trouble of finding the ratio of the ſide of the *polygon* to radius, by the canon of lines; we ſhall add a table expreſſing the ſides of *polygons* in ſuch parts whereof radius contains 100000000. In practice, as many figures are cut off from the right hand, as the circumſtances of the caſe render needleſs.

Numb. Sides.	Quantity Side.	Numb. Sides.	Quantity Side.
III.	173205080	VIII.	76536768
IV.	141421356	IX.	68404028
V.	117557050	X.	61803399
VI.	100000000	XI.	56341950
VII.	86776748	XII.	51763809

POLYGON, *to describe a regular, on a given right line, and to circumscribe a circle about a given polygon, trigonometrically.* Taking the ratio of the side to the radius out of the table, find the radius in the same measure wherein the side is given. For the side and radius being had, a *polygon* may be described by the last problem. And if with the interval of the radius, arcs be struck from the two extremes of the given line, the point of intersection will be the centre of the circumscribing circle.

POLYGON, in *Fortification*, denotes the figure or perimeter of a fortress, or fortified place. See FORTIFICATION.

POLYGON, *exterior*, is a right line drawn from the vertex or point of a bastion, to the vertex or point of the next adjacent bastion. Such is the line CF: *Tab. fortif. fig.* 1.

POLYGON, *interior*, is a right line drawn from the centre of one bastion to the centre of another. Such is the line GH.

POLYGONS, *line of*, is a line on the French sectors, containing the homologous sides of the first nine regular *polygons* inscribed in the same circle, i. e. from an equilateral triangle to a dodecagon. See SECTOR.

POLYGONAL *column.* See COLUMN.

POLYGONAL *number*, in *Algebra*, is the sum of a rank of numbers in arithmetical progression, beginning from unity: thus called, because the units, of which it consists, may be so disposed as to represent a figure of several equal sides and angles.

Polygonal numbers are divided, with respect to the common difference in the series whence they proceed, or whose sums they are, into *triangular*, which are those whose difference of terms is 1; *quadrangular* or *square*, where it is 2; *pentagonal*, where 3; *hexagonal*, where 4; *heptagonal*, where 5; *octagonal*, where 6, *&c.*

They have their names from the geometrical figure, into which points corresponding to their units may be disposed; e. gr. three points, corresponding to the three units of a triangular number, may be disposed into a triangle; and four of the rest.

The genesis of the several kinds of *polygonal* numbers from the several arithmetical progressions, may be conceived from the following examples:

Arithmetical progression	1.	2.	3.	4.	5.	6.	7.	8
Triangular numbers	1.	3.	6.	10.	15.	21.	28.	36
Arithmetical progression	1.	3.	5.	7.	9.	11.	13.	15
Square numbers	1.	4.	9.	16.	25.	36.	49.	64
Arithmetical progression	1.	4.	7.	10.	13.	16.	19.	22
Pentagonal numbers	1.	5.	12.	22.	35.	51.	70.	92
Arithmetical progression	1.	5.	9.	13.	17.	21.	25.	29
Hexagonal numbers	1.	6.	15.	28.	45.	66.	91.	120

POLYGONAL *number, side of*, is the number of terms of the arithmetical progression that compose it: and the number of angles is that which shews how many angles that figure has, whence the *polygonal* number takes its name.

The number of angles, therefore, in triangular numbers, is 3; in tetragonal 4, in pentagonal 5, &c. Consequently the number of angles exceeds the common difference of terms, by two.

To find a POLYGONAL *number, the side and number of its angles being given.* The canon is thus: the *polygonal* number is the semi-difference of the factums of the square of the side into the number of angles diminished by two units; and of the side itself into the number of angles diminished by four units.

The sums of *polygonal* numbers collected in the same manner as the *polygonal* numbers themselves are, out of arithmetical progressions, are called *pyramidal numbers*.

POLYGONATUM, in *Botany*. See LILY *of the Valley*.

POLYGONOIDES *of Dillenius*, in *Botany*. See CORRIGIOLA.

POLYGONOIDES, in *Botany*. See CALLIGONUM.

POLYGONUM, in *Botany*. See KNOT-*grass*.

POLYGRAM, in *Geometry*, a figure consisting of many lines.

POLYGRAPHY, POLYGRAPHIS, or POLYGRAPHICE, formed from πολυς, *multum*, and γραφω, *scripturo*, *writing*, the art of writing in various unusual manners or ciphers; as also the art of deciphering the same.

The word is usually confounded with STEGANOGRAPHY, and CRYPTOGRAPHY.

The ancients seem to have been very little acquainted with this art; nor is there any mark of their having gone beyond the Lacedæmonian SCYTALE.

Trithemius, Porta, Vigenere, and father Niceron, have written on the subject of *polygraphy*, or CIPHERS.

POLYHEDRON, or POLYEDRON, Πολυεδρον, formed from πολυς, *multus*, and εδρα, *sedes*, in *Geometry*, a body comprehended under many rectilinear sides or planes.

If the sides of the *polyhedron* be regular *polygons*, all similar and equal; the *polyhedron* becomes a regular body, and may be inscribed in a sphere; that is, a sphere may be drawn round it, so that its surface shall touch all the solid angles of the body.

POLYHEDRON, *gnomonic*, is a stone with several faces, whereon are projected various kinds of dials. See DIAL. Of this kind that in the Privy-garden, London, now gone to ruin, was anciently the finest in the world.

POLYHEDRON, or POLYSCOPE, in *Optics*, is a glass or lens, consisting of several plain surfaces, disposed into a convex form; popularly called a MULTIPLYING-*glass*. The phenomena of the *polyhedron* are as follow: 1. If several rays, as E F, A B, C D (*Tab. V. Optics, fig.* 91.) fall parallel on the surface of a *polyhedron*, they will continue parallel after refraction.

If then the *polyhedron* be supposed regular, I H, H I, I M, will be as tangents cutting the spherical convex lens in F, B, and D; consequently, rays falling on the points of contact, intersect the axis. Wherefore, since the rest are parallel to these, they will also mutually intersect each other in G.

Hence, if the eye be placed where parallel rays decussate, rays of the same object will be propagated to it still parallel from the several sides of the glass. Wherefore, since the crystalline humour, by its convexity, unites parallel rays, the rays will be united in as many different points of the retina, *a*, *b*, *c*, as the glass has sides.

Consequently, the eye, through a *polyhedron*, sees the object repeated as many times as there are sides. And hence, since rays coming from remote objects are parallel, a remote object is seen as often repeated through a *polyhedron*, as that has sides.

2. If rays A B, A C, A D (*fig.* 92.) proceeding from a radiant point A, fall on several sides of a regular *polyhedron*; after refraction they will decussate in G, and proceed on a little diverging.

Hence, if the eye be placed where the rays coming from the several planes decussate, the rays will be propagated to it from the several planes a little diverging; i. e. as if they proceeded from different points. But since the crystalline humour, by its convexity, collects rays from several points into the same point; the rays will be united in as many different points of the retina, *a*, *b*, *c*, as the glass has sides; consequently, the eye, being placed in the focus G, will see even a near object repeated as often through the *polyhedron*, as that has sides.

Thus may the images of objects be multiplied in a camera obscura, by placing a *polyhedron* at its aperture, and adding a convex lens at a due distance from it. And it makes a very pleasant appearance, if a prism be applied so that the coloured rays of the sun refracted therefrom be received on the *polyhedron*: for by this means they will be thrown on a paper or wall near at hand in little round specks, much exceeding the brightness of any precious stones; and in the focus of the *polyhedron* where the rays decussate (for in this experiment they are received on the convex side) will be a star of surprising lustre.

If images be painted in water-colours in the areolæ or little squares of a *polyedron*, and the glass applied to the aperture of a camera obscura; the sun's rays, passing through it, will carry with them the images thereof, and project them on the opposite wall.

This artifice bears a resemblance to that other, whereby an image on paper is projected on the camera; viz. by wetting the paper with oil, and straining it tight in a frame; then applying it to the aperture of the camera obscura, so that the rays of a candle may pass through it upon the *polyhedron*.

To make an anamorphosis, or deformed image, which through a POLYHEDRON, *or* multiplying-glass, *shall appear regular and beautiful.* At one end of a horizontal table erect another at right angles, whereon a figure may be designed; and on the other erect another, to serve as a fulcrum or support, moveable on the horizontal one. To the fulcrum apply a plano-convex *polyedron*, consisting, e. gr. of twenty-four plain triangles; let the *polyhedron* be fitted in a draw-tube, whereof that end towards the eye to have only a very small aperture, and a little farther off than the focus. Remove the fulcrum from the other perpendicular table, till it be out of the distance of the focus; and that more, as the image is to be greater. Before the little aperture place a lamp; and trace the luminous areolæ projected from the sides of the *polyhedron*, with a black lead pencil, on the vertical plane, or a paper applied thereon.

In the several areolæ, design the several parts of an image, in such a manner as that, when joined together, they may make one whole, looking afresh every now and then through the tube to guide, correct, &c. the colours, and to see that the several parts match aptly together.

The intermediate space fill up with any figures or designs at pleasure, contriving it so, as that to the naked eye the whole may exhibit some appearance very different from that intended to appear through the *polyhedron*.

The

The eye, now looking through the little aperture of the tube, will see the several parts and members dispersed among the areolæ to exhibit one continued image, all the intermediate ones disappearing. See ANAMORPHOSIS.

POLYHEDROUS *figure*, in *Geometry*, a solid contained under, or consisting of many sides. See POLYEDRON.

POLYHISTOR is used for a person of great and various erudition. See POLYMATHY.

POLYHYMNIA, in *Mythology*, one of the nine MUSES, distinguished among authors and poets by holding some stringed instrument of music in her hands, and by marking out what the sings with her hand.

POLYMATHY, POLYMATHIA, Πολυμαθία, from πολὺς, *multum*, and μανθάνω, *disco*, *I learn*, the knowledge of many arts and sciences; or an acquaintance with a great number of different subjects.

Lipsius, Scaliger, Kircher, Petavius, Grotius, Salmasius, Leibnitz, &c. were famous for *polymathy*. Among the ancients, such as were eminent this way were called *polyhistores*.

Polymathy is frequently little more than a confused heap of useless erudition, occasionally detailed, either pertinently or impertinently, for parade. The genuine *polymathy* is an extensive erudition, or a knowledge of a great number of things, well digested, and applied to the purpose, and never but where they are necessary.

POLYMNIA, in *Botany*, a genus of the *Syngenesia polygamia æqualis* class: its characters are, that the receptacle is chaffy, and that there is no down; the exterior calyx is composed of five leaves, and the interior of ten, with small concave leaves. There are four species.

POLYMORPHOUS, variously shaped, an epithet often given to the os sphenoides.

POLYMYTHY, POLYMYTHIA, in *Poetry*, denotes a multiplicity of fables, in an epic or dramatic poem; in lieu of an unity, or a single one.

Polymythia is a great fault. It consists in joining a number of distinct actions or fables into one complex body. Such a work Bossu compares to the batrachomyomachia, or one of the fables of *Æsop*: and such would be the idea of a Thebaid, an Heracleid, an Achilleid, or the like poems, which should comprehend all the actions of those heroes compared with the Iliad or Æneid.

POLYNEMUS, *four-cleft*, in *Ichthyology*, a genus of the *abdominales*: its characters are, that the head is compressed and squamous; the beak is very obtuse and prominent; the gills consist of five or seven rays; and there are several distinct processes or appendages placed with the pectoral fins. There are three species, one of which is the parasite-fish of Edwards.

POLYNOMIAL, or *multinomial root*, in *Mathematics*. See MULTINOMIAL, and ROOT.

To raise a *polynomial* to any given power, may be done by its base Newton's BINOMIAL theorem. Among other methods of demonstrating this, we have one by Signor Castillioni in the Philosophical Transactions, N° 464.

POLYOPTRUM, formed from πολὺς, *much*, *many*, and ὀπτικὸν, *I see*, in *Optics*, a glass through which objects appear multiplied, but diminished.

The *polyoptrum* differs both in structure and phenomena from the common multiplying-glasses called *polyscopes*.

POLYOPTRUM, *construction of the*. In a glass, plain on both sides, AB (*Tab.* V. *Optics*, *fig.* 93.) and about three fingers thick, cut out spherical segments, scarce a fifth part of a digit in diameter.

If then the glass be removed from the eye, till you can take in all the cavities at *one* view, you will see the same object, as if through so many several concave glasses, as there are cavities, and all extending small.

Fit this, as an object-glass, in a tube ABCD, whose aperture AB is equal to the diameter of the glass, and the other CD is equal to that of an eye-glass, e. gr. about a finger's breadth. The length of the tube AC is to be accommodated to the object and eye-glass, by trial. In CD fit a convex eye-glass, or in lieu thereof a meniscus having the distance of its principal focus a little larger than the length of the tube; to that the point from which the rays diverge after refraction in the object-glass, may be in the focus. If then the eye be applied near to the eye-glass, a single object will be seen repeated as often as there are cavities in the object-glass, but still diminished.

POLYOSTEON, a name given by authors to that part of the foot which contains of a great many bones.

POLYPE, or POLYPUS, in *Zoology*, a small fresh water insect, belonging to the genus of HYDRA, in the class of *worms*, and order of *zoophyta*, in the Linnæan system; which, when cut into a number of separate pieces, becomes in a day or two so many distinct and separate animals; each piece having the surprising property of producing a head and tail, and the other organs necessary for life, and all the animal functions. *See Tab. of Microscopical Objects*, *fig.* 1.

The first discovery of this animal was owing to M. Leeuwenhoek, who, in the year 1703, presented to the Royal Society of London, a description of it, and an account of its uncommon way of propagating its young: but the discovery of its amazing property of reproducing the several organs from its various pieces, was not made till the year 1740, by M. Trembley, at the Hague. See Martyn's Abr. Phil. Trans. vol. ii. p. 17, &c.

The production of its young is, indeed, different from the common course of nature in other animals: for the young one issues from the side of its parent, in form of a small pimple or protuberance, which, lengthening and enlarging every hour, becomes, in about two days, a perfect animal, and drops from off its parent to shift for itself; but before it does this, it has often another growing from its side; and sometimes a third from it, even before the first is separated from its parent.

M. Trembley observes, that there is no distinguished place in the body of the *polypes*, by which the young are brought forth. He has seen some of them that have produced young ones from all the exterior parts of their bodies.

They breed quicker in hot than in cold weather; and what is very extraordinary is, that there never has yet been discovered among them any distinction of sex, or appearance of copulation; every individual of the whole species being prolific, and that so much if kept separate, as if suffered to live among others.

If the method of this little animal's producing its young be very amazing, its reproduction of the several parts, when cut off, is much more so. The discovery of this was perfectly accidental; for M. Trembley, who had often met with the creature in the winter, and from its fixed residence in one place, and some other observations, not being able to determine whether it were an animal or a vegetable, made the trial by cutting it asunder, when, to his amazement, he found, that in a few days each of those pieces was become a perfect animal, the head part having shot forth a tail, and the tail a head.

A thousand other trials, by cutting the animal in different manners, first by M. Trembley, and afterwards, at his request, by Mons. Reaumur, and Bernard de Jussieu, at Paris, and Mrs. Folkes, Mr. Baker, and the other naturalists in England, were the result of this; and all succeeded in the same manner by those who repeated them.

It is not easy to say what is the size of this creature; for it can contract or extend its body at pleasure from the length of an inch or more, and the thickness of a hog's bristle, to the shortness of a single line, with a proportionable increase of thickness. Its body is round and tubular, at one end of which is the head, surrounded with six, eight, ten, or more arms, with which it catches its prey; and at the other, the anus and tail, by which it fixes itself to any thing it pleases.

There have been many different species of it discovered, the most elegant of which, the *polype à panache*, or plumed *polype*, of Mr. Trembley, seems much to resemble the wheel-animal (so called from having the appearance of two wheels in its head) which Mr. Leeuwenhoek discovered, living in a tooth or cafe, and affixed to the roots of duck-weed.

All the species are found in clear and slowly running waters, adhering by the tail to sticks, stones, and water-plants, and live on small insects. They are easily kept alive a long time in glasses, often changing the water, keeping the glasses clean, and feeding them with a small red worm, common in the mud of the Thames, or with other small insects.

The creature has its name from the Greek πολὺς, *many* and πὸυς, *a foot*, signifying an animal with many feet; but a more apposite one might easily have been invented, since it has in reality no feet at all. What were originally taken for feet, are what have since been called its horns, and of late more properly its arms, their office being to catch its prey.

This animal, represented in the plate of *Microscopical Objects*, &c. above referred to, is, first, of a worm-shaped figure, and of the same kind of tender substance with the horns of a common snail; is adhered by one end, like a sucker, to water-plants and other substances; the other end, which is the head, is surrounded by many arms or feelers, placed like rays round a centre; this centre is its mouth; and with these tender arms, which are capable of great extension, it seizes minute worms, and various kinds of water insects, and brings them to its mouth; and often swallows bodies larger than itself; having a surprising property of extending its mouth wider, in proportion, than any other animal. After its food is digested in its stomach, it returns the remains of the

animals upon which it feeds through its mouth again, having no other observable emunctory. In a few days there appear small knobs or *pupillæ* on its sides: as these increase in length, little fibres are seen rising out of the circumference of their heads, as in the parent animal; which fibres they soon begin to use for the purpose of procuring nourishment, &c. When these are arrived at mature size, they send out other young ones on their sides in the same manner; so that the animal branches out into a numerous offspring, growing out of one common parent, and united together and disposed in the manner represented in the plate. Each of these provides nourishment not only for itself, but for the whole society; an increase of the bulk of one *polype* by its feeding, tending to an increase in the rest. Thus a *polype* of the fresh-water kind becomes like a plant branched out, or compound of many bodies, each of which has this singular characteristic, that if one of them be cut in two in the middle, the separated part becomes a complete animal, and soon adhering to some fixed base, like the parent from which it was separated, produces a circle of arms; a mouth is formed in the centre; it increases in bulk, emits a numerous progeny, and is, in every respect, as perfect an animal as that from which it was severed.

The several strange properties recorded of this animal, though very surprising, are, however, none of them peculiar to it alone. The Surinam toad is well known to produce its young not in the ordinary way, but in cells upon its back. Mr. Sherwood has very lately discovered the small eels in four paste to be each, without exception, full of living young ones. And as to the most amazing of all its properties, the reproduction of its parts, we know the crab and lobster, if a leg be broken off, always produce a new one: and M. Bonet, M. Lyonet, Monsieur Reaumur, and Mr. Folkes, have all found, on experiment, that several earth and water worms have the same property, some of them even when cut into thirty pieces. The *urtica marina*, or sea-nettle, has been also found to have the same: and the sea star-fish, of which the *polype* is truly a species, though it had long escaped the searches of the naturalists, was always well known by the fishermen to have it also. See REPRODUCTION.

POLYPE, *cluster*, the name of a species of small insect of the *polype* kind, called by the French naturalists *polype en bouquet*.

There is found on several of the water-plants, and on other substances, as sticks, boards, and the like, accidentally fallen into the water, a whitish substance that at first sight appears to be only a sort of mouldiness; but if the bodies on which this is found be put into a vessel of clear water, and the matter examined with a magnifying glass, it is soon seen that this whitish substance is really a vast number of small animals, which are almost continually in motion. When this is brought before the microscope, the form and structure of the creatures are very evidently distinguished, and they are found to be minute roundish creatures, severally affixed to the end of a sort of stem or tail; and many of the stems are so interwoven and united together, that they form *clusters*, which have occasioned the name of a *cluster-polype* to be given to the animal, though in itself it is really and properly single from the beginning. There are several species of *polype* of this minute kind, that *cluster* themselves in this manner together; and according to these and other circumstances, the *clusters* are found larger or smaller, and more or less complex.

The smaller *clusters* should always be chosen for observation, as in the larger the bodies of the several animals that compose them are apt to hide and obscure one another; but the most beautiful and accurate of all observations is to be formed when they are single, as they are sometimes found; and this is the only opportunity of seeing distinctly in what manner the *clusters* are formed. One of these single animals is not in length above the two hundred and fortieth part of an inch, and is of a shape nearly resembling that of a bell: the anterior part of the generally appears open when it presents itself properly; and the posterior part is fixed to the stem or pedicle, by the other extremity of which the creature fastens itself to any solid body that it meets with. The body is of a brownish colour, except at the smaller end, which as well as the tail is whitish and transparent; and when the anterior part is open, there may always be perceived about its edges a very lively motion; and when the creature presents itself in a better manner, there may be seen on either side of the edges of the anterior part, somewhat resembling the wheels of a mill, continually moving with great velocity.

These creatures are able to contract their bodies, and often do it very suddenly, especially if any thing disturb the substance on which they are fixed: when they are thus contracted, the edges of their anterior parts are drawn just into their bodies; and when the fright is over, it is a very agreeable sight to behold these edges turning out again, and putting themselves in motion as before. If the edges of the anterior parts of the bodies of these animals be strictly observed while in motion, the water about them will be found to be full of extremely minute round bodies, which are brought together by means of that motion, and serve the creature for its food: these may be often seen going down into the cavities of the body of the *polype*, and that very suddenly, as if forcibly driven down; and when swallowed too voraciously, are often thrown up again. These observations are best made when a small *cluster* of the *polypes* are examined together.

If these *polypes* are kept some time in the rain water, they by degrees lose their brown colour, and become white and transparent throughout, except that a few spots, of a dusky colour, remain in their bodies; but if, after this, they are removed into other water of the same kind with the first, but newly taken out of the ditch, they in a little time recover their brown colour. When they become white, they plainly appear to be in a sickly condition, and cease to multiply; but when they have fresh water and recover their colour, they immediately begin to multiply again.

These creatures are not absolutely and immoveably fixed to the bodies on which they are placed, but they can at pleasure quit them and swim about: in this swimming state they are always found single and not in *clusters*; and they do not then appear in the same form as when they are fixed and open at the anterior ends. When they have swam about as long as they please, they either return to their *clusters* from which they separated themselves, or affix each singly to any thing they meet with: and this is a circumstance that merits to be carefully watched, because it is by means of this that we see in what manner the creature multiplies itself, and the *clusters* are formed.

As soon as a single animal of this kind is fixed to a stick, a stone, or any other substance, it begins to lengthen its stem or tail, which, though very short while swimming, and when first fixed, very soon becomes of its prisline length while in the *cluster*; and after this the creature begins immediately to multiply by the most amazing means in the world, that is, by splitting itself to pieces lengthways. The first motion towards this operation is the drawing in the lips or edges; this is soon done, and the body then loses its bell-like shape, and becomes round; the motion which was before perceived at the edges ceases, and there is only a slight undulation to be seen within the body; after which the anterior part of the body becomes flat and broad, and the whole body shortens in proportion; and soon after this the whole body gradually splits itself regularly into two, from the centre of the anterior part to the centre of the hinder end, where it joins the tail or pedicle, and there soon appear two round and perfect bodies joined to that pedicle which before supported only one. The anterior parts of the two bodies soon begin to open, and gradually shew their edges, which perform the same motion the single one did before. The motion is at first very slow, but it grows quicker by degrees as they open; and when they are perfectly expanded, it is as quick as it was in the original single body: it is at this time that the two bodies may be esteemed quite perfect. They are at first indeed less than the original *polype*, from which they were formed, but they grow to the same size in a very little time: the whole operation of dividing itself, takes up the creature about an hour; but to form a true idea of the manner in which it is performed, there must be many observations made, and the creatures must be examined in all views and lights while about it.

The lips of these *polypes*, when closely examined, appear to be composed of four or five transparent bands, all of which have an undulatory motion. And when the newly divided *polype* is but flow in its motions, it is easy to discover that what afterwards appear to be like the wheels of a mill, are, in reality, only four or five oblong bodies, resembling a sort of fingers which alternately bend down, and extend themselves every instant. These are fastened to the bands of the lips on each side of the mouth; and when they are put into swift motion in the time of the full growth and vigour of the animal, they are not to be distinguished, as to form, nor can their motion be otherwise discovered than by its effects, which makes it resemble the quick turning of a wheel.

When the separation of the body of a single *polype* of this kind is complete, one fora two regular and perfect bodies adhering side by side to the same pedicle, but soon after each of the new formed bodies begins to throw a pedicle of its own; these grow in a days time to a moderate

length, and unite at their bottoms to the end of what what was the original fingle peſtiele of the body while but one; they grow to this in the manner of the branches growing to the trunk of a tree.

Twenty-four hours after the ſeparation of the original body into two, theſe two begin to ſeparate themſelves in the ſame manner, each into two again; and theſe, after a like time, again ſeparate: each of theſe ſeparated animals has its own tail formed in a like period of time with the firſt; and the conſequence is, that the firſt ſeparation producing two, the ſecond gives four, the third eight, and ſo the fifth ſixty-four, the ſeventh one hundred and twenty-eight, and ſo on; by which means a ſingle animal, in a very few days, forms out of itſelf, an immenſe *cluſter*, each animal of which is perfect in itſelf, and independent of all the reſt, and can, when it pleaſes, ſwim away and form a new *cluſter*. They will multiply as faſt in glaſs jars, as in their native free ſtate in the waters, and *cluſters* of them, begun near one another, will often join in ſuch a manner as to form one complex *cluſter* of an inch diameter; from theſe ſeveral *cluſters* there detach themſelves ſingle *polypes* from time to time, which go off, and, faſtening themſelves to other bodies, become the authors of new progenies.

The original branch or ſtem of the firſt *polype* remains always in the centre of the *cluſter*; but it is of no uſe, never afterwards having any body fixed to it.

There are, beſide this ſpecies here deſcribed, four other known kinds of *polypes*, which divide themſelves in the ſame manner by ſplitting into two lengthwiſe: thoſe which come neareſt to the firſt are ſlenderer, and their ſtems are more tranſparent. They are of a bluiſh colour, when many of them are ſeen together, and their ſtems or tails very aptly reſemble ſpun glaſs. When this ſpecies is perfectly formed, the motion of its lips is leſs diſtinct than in the other; but it may be diſcovered in the ſame manner while they are newly ſeparated, and are but growing toward perfection, when it gradually becomes leſs and leſs diſtinct.

Another ſpecies of theſe *polypes* is ſmaller than the laſt, but more open at the mouth and deeper hollowed; and theſe are particularly diſtinguiſhed from all the others, by having a motion in their ſtems and branches, which all the others want. The ſtems draw themſelves up, and ſhorten all at once into the appearance of a ſpiral ſcrew, and in a moment can dart themſelves ſtraight out to their full length again. All theſe multiply very ſpeedily, but they have all enemies that deſtroy them in a very terrible manner, whole *cluſters* mating but ſingle mouthfuls. The *funnel-polypes* are nearly allied to theſe creatures. Phil. Tranſ. N° 474, vol xliii. p. 169, &c. and vol. xliv. p. 627, &c.

POLYPE, *funnel*, a name given by naturaliſts to a ſmall water-inſect, in ſome reſpects approaching to the nature of the *cluſter-POLYPE*.

The *funnel-polype* nearly reſembles a funnel, from which it has its name. It is long and hollow, and very wide at the anterior end. Theſe little animals are of three ſpecies, a green, a blue, and a white one: they are all too minute for the obſervation of the naked eye, and muſt be viewed with great caution, and in ſeveral different directions and attitudes, before their true form can be diſcovered; and their anterior end, particularly when carefully obſerved, is of a much more compound ſtructure than might at firſt be imagined; there may always be obſerved, round the edges of this part, a ſenſible motion, reſembling that of an indented wheel, or rather that of a ſcrew turned very nimbly about. Theſe, though they approach to the ſhape of the cluſter-*polypes*, and reſemble them in their having this motion about the mouths, yet never have any tendency to form cluſters, but are ever found looſe and ſingle. There are always a number of little round bodies, which ſeem to be animals of a very minute ſize, ſwimming about in the water in which theſe *polypes* live; and theſe are continually drawn into the mouths of the *polypes*, and ſerve them for food.

The manner of theſe creatures propagating themſelves is very amazing; they do it by dividing their own body into two; but this is not done longitudinally, as in the cluſter-*polypes*, nor tranſverſely, but diagonally from the edge of the head to the oppoſite edge of the tail; ſo that of the two thus formed out of one, the one has a head and no tail, the other a tail and no head; but theſe deficiencies are ſoon made up, and the head ſoon grows out of one, and the tail out of the other.

M. Trembley, in his account of this inſect, calls that of the two which has the old head, the ſuperior *polype*; that which has the old tail, the inferior. The firſt particulars obſervable in a *funnel-polype* that is going to divide, are the lips of the inferior *polype*, or thoſe tranſparent edges, that are ſo very conſpicuous in the creature when perfectly formed. Theſe new lips firſt diſcover themſelves upon the *polype* that is going to divide, from a little below the old lips to about two-thirds of the length of the *polype*, reckoning from the head: but theſe new lips are not diſpoſed in a ſtraight line, according to the length of the *polype* but run ſloping near half way round about. Theſe lips are diſtinguiſhed by their motion; but it is to be obſerved, that this motion is at firſt very ſlow, and requires an attentive eye and good glaſſes to diſcover it.

That portion of the body of the *polype* which is bounded by theſe new lips, then gathers up itſelf, and theſe lips inſenſibly draw cloſe together, and finally, they cloſe themſelves. By this means there is formed a ſwelling at the ſide of the *polype*, which is found on cloſe examination, to be the head of the new *polype*, bounded by the lips before mentioned. Before this ſwelling is become very remarkable, it is eaſy to diſcover the true *polypes* that are forming themſelves; and, after this, when the ſwelling is greatly increaſed, theſe two diſtinct animals will be found joined to one another only by a very ſmall part of their bodies. The ſuperior *polype*, in this caſe, no longer adheres to the inferior one but by its poſterior extremity, which is ſtill fixed on one ſide of the inferior one. The ſuperior one then begins to make motions, which tend to the ſeparating itſelf from its fellow; and theſe ſoon finiſh the work, and he becomes perfectly diſengaged, and ſwims away whither he pleaſes, and ſoon fixes on ſome other place. The inferior *polype* remains fixed in the place where both were before, and becomes a perfect animal; and the ſuperior one, after taking a tour in the water, ſometimes returns to the old place, and fixes himſelf by the tail to the body of the inferior one. All theſe animals are extremely minute, and are not to be ſeen diſtinctly, much leſs are their operations obſerved without the help of glaſſes; and as there is no taking them out of the water to bring them before the microſcope in the common way, without abſolutely deſtroying them, M. Trembley, who has obſerved them with more accuracy than perhaps any other perſon ever did, has contrived to view them in a glaſs veſſel, in their own water, by bringing them ſo near the ſides of the glaſſes, that the microſcope glaſſes are able to reach them properly from the outſide. The ſubſtances on which they are fixed, are to be brought cloſe to the edges of the veſſel, by means of a ſet of quills framed properly together; and the microſcope glaſſes to be ſupported on a moveable arm made for that purpoſe. Phil. Tranſ. N° 474. vol xliii. p. 180, &c. and vol. xliv. p. 627, &c.

POLYPE, *marine*, is different in form from the freſh water POLYPE already deſcribed, but is nouriſhed, increaſes, and may be propagated after the ſame manner: Mr. Ellis having often found, in his inquiries, that ſmall pieces cut off from the living parent, in order to view the ſeveral parts more accurately, ſoon gave indications that they contained not only the principles of life, but likewiſe the faculty of increaſing and multiplying into a numerous iſſue. It has been lately diſcovered and ſufficiently proved by Peyſſonel, Ellis, Juſſieu, Reaumur, Donati, &c. that many of thoſe ſubſtances, which had formerly been conſidered by naturaliſts as marine vegetables or ſea-plants, are in reality animal productions; and that they are formed by *polypes* of different ſhapes and ſizes, for their habitation, defence, and propagation. To this claſs may be referred the CORALS, CORALLINES, KERATOPHYTA, ESCHARA, SPONGES, and ALCYONIUM: nor is it improbable that the more compact bodies, known by the common appellations of ſtar-ſtones, brain-ſtone, petrified fungi, and the like, brought from various parts of the Eaſt and Weſt Indies, are of the ſame origin: to this purpoſe Mr. Ellis obſerves, that the ocean, in all the warmer latitudes near the ſhore, and wherever it is poſſible to obſerve, abounds ſo much with animal life, that no inanimate body can long remain unoccupied by ſome ſpecies. In thoſe regions the ſhips' bottoms are ſoon covered with the habitations of thouſands of animals: rocks, ſtones, and every thing liſeleſs, are covered with them inſtantly: and even the branches of living vegetables that hang into the water, are immediately loaded with the ſpawn of different animals, ſhell fiſh of various kinds. And ſhell fiſh themſelves, when they become impotent and old, are the baſis of new colonies of animals, from whoſe attacks they can no longer defend themſelves. For a farther account of this ſyſtem, ſee CORAL, and CORALLINES.

POLYPE, *vor.* See VER-*polype*.

POLYPETALOUS, from πολυς, *multum*, and πεταλον, *petalum*, in *Botany*, a flower conſiſting of ſeveral petals, or leaves.

The corollæ of flowers conſiſt either of a ſingle continued petalon, whence they are called *monopetalous*; or of ſeveral diſtinct pieces, whence they are named *polypetalous*.

Polypetalous flowers are either *regular* or *irregular*.

POLYPETALOUS *flowers, regular*, according to some botanists, are either those consisting of two pieces, as the cucumis flower; or of four, thence called *cruciform-flowers*, as the flower of the clote-tree; or of five, usually *umbelliferous*, as fennel; or of six, as the white lily, thence called the *lily-kind*.

Those exceeding this number, in any quantity, equal or unequal, form a new class of *polypetalous* flowers; among which are also ranked all those whose fruits differ to from the rest, that the rules of genera require that they be distinguished from them.

Such is the flower of the water-plantain, which though it has only three leaves, yet, by the relation of its seed with that of the ranunculus, is ranged in this last class.

Such also is the flower of tormentil; which, by reason of the difference of its fruit from the silique or filicule of the cross-flowers, cannot be ranged among them.

Such also is the pink, which, though consisting of five pieces, yet is excluded the class of umbelliferous plants, because its fruit is not divided into two parts. Such, lastly, are the flowers of some ranunculuses, house-leek, and anemonies; which, though they have six petals, yet never produce fruits divided into three lodges, as those of the lily-kind; and therefore cannot belong to their class.

POLYPETALOUS *flowers, irregular*, are so called from the odd figure and disposition of their petals, what number of them soever they have.

Such are those two pieces resembling two chaps, as in fumitory; or those of five pieces resembling butterflies: these last are common to all leguminous plants.

POLYPHEMUS, in *Astrology*, the most celebrated and the most terrible of the CYCLOPES, who were deemed to be the sons of Neptune.

POLYPODES, a word used by some as the name for the MILLEPEDES.

POLYPODITES, a name given by the ancients to a wine impregnated with polypody, and sometimes for the juice of millepedes, expressed with wine.

POLYPODY, in *Botany*. See *POLYPODY*.

POLYPODY, *polypodium*, in *Botany*, a genus of the *cryptogamia filices* class. Its characters are these: it is distinguished from the other plants of the fern tribe by the fructification being in roundish spots, distributed on the under surface of the leaf. Miller.

There are many species of this plant. Tournefort enumerates twenty-six; Miller two; and Linnæus sixty-four.

The *polypodies* are not branched, but consist of single leaves, divided almost to the middle rib into oblong jags or segments.

The word is formed from the Greek πολυς, and πους, *foot*, in regard the root of the plant clings to walls and trees, by a great number of little fibres like claws.

The common *polypody*, with wing-pointed leaves having oblong obtuse lobes, which are somewhat sawed, and a scaly root, is the kind used in medicine; it is usually found about the roots of old trees, in woods, and by hollow road sides: and is green all seasons of the *year*.

There is a vulgar opinion, that such of it as grows upon the stump of an oak, thence called *oak-polypody*, is preferable to what grows on any other tree; but there is no foundation for this.

The root is the part used in medicine; it is a gentle cathartic, and has been recommended in disorders arising from obstructions of the liver and spleen. It is by many esteemed an excellent medicine in scorbutic and hypochondriac complaints. The country people take it in infusion alone, but physicians usually prescribe it in compound decoctions and medicated ales. It has also been made an ingredient in many of the purging electuaries in the old dispensatories.

However, though it has been supposed to be aperient, resolvent, and expectorant, and formerly ranked among the purgatives, its operation is so weak, a decoction of an ounce or two scarcely moving the belly, that it has been long expunged from the latter class, and the present practice very little regards it in any intention.

POLYPOSIA, a term used by the ancients to express a copious drinking of wine.

POLYPREMUM, *Cuckoo-flax*, in *Botany*, a genus of the *tetrandria monogynia* class: its characters are, that it has a four-leaved calyx; a rotated corolla divided into four segments, with heart-shaped lobes; and that the fruit is a compressed emarginated capsule, with two cells. There is only one species.

POLYPTOTON, ΠΟΛΥΠΤΩΤΟΝ, in *Rhetoric*, a figure wherein the same words are repeated in different cases, genders, or numbers, i. e. with different terminations.

Such is that of Cicero, pro Arch. *Sed plori sunt omnes, flere, plorare fortissimum, vereri, plena exemplorum vetustas.* So Virg. Æn. lib. ix. v. 28.

Linora litteribus contraria, fluctibus undas
Imprecor, arma armis pugnæque cruentæ.

POLYPUS, the *polypus* in *Zoology*. See POLYPE.

POLYPUS, in *Natural History*, a name given by some of the earlier writers to the thin-shelled nautilus, or nautilus papyraceus. The body and arms of this creature somewhat resemble those of the polypus; it was supposed to be a species of polypus inclosed in a shell, which it could quit occasionally, and go on shore to feed.

POLYPUS, NOSE, or *NARES*, in *Surgery*, a fleshy tumor or excrescence arising from the inside of the nostrils, prejudicial to respiration and speech; called also by way of distinction, *polypus narium*.

This *polypus* arises by several roots from the os cribriforme, and hangs down, sometimes as low as the lips, growing likewise backwards, so as to stop the hole of the palate, whereby the air and pituita descend out of the nose down into the throat; and by this means strangling the patient. It has its name from the resemblance it bears to the fish *polypus*, called the *four-footed*, or *many feet*. Some derive the name from the resemblance its substance bears to that of the *polypus*; and others, from the resemblance in many roots bear to the many feet of that fish.

If it have no roots, or only one continued root, it is called a SARCOMA, which is only a beginning *polypus*.

Polypuses are chiefly found in scrophulous or cancerous constitutions, along with venereal cases, ulcers, ozænas, &c. Caustics, emollient fomentations, extirpation, and deficcative powders, and lotions, are the usual remedies. M. Le Dran cured a *polypus* of the nose, which he could not extract wholly, in the following manner, which may be practised for destroying all such excrescences. He introduced one end of a large seton, put on the point of the fore-finger of the left hand, into the patient's mouth, till he brought it behind the velum pendulum; then filling a pair of thin crooked forceps into the affected nostril, he catched hold of the seton, after covering what was to be introduced into the nose with a suppurant medicine. While he drew the cord, he endeavoured to preserve the velum pendulum from being hurt, by introducing his finger into the mouth, and supporting the cord upon it. He continued the suppurant till he was sensible, by the patient's breathing freely through the nostril, that the remains of the *polypus* was destroyed, and then he injected deficatives to cauterize the ulcer. Le Dran, tom. i. obs. 6. sp. Med. Ed. Edinb.

POLYPUS is also used for a morbid excrescence in the heart, consisting of a tough concretion of grumous blood lodged therein. Malpighi gives a very accurate description of this *polypus*. In the right ventricle of the heart, he observes, it is usually larger, and of a paler colour, like pimita, with reddish or blackish streaks; in the left ventricle it is smaller, blacker, and denser. He adds, that it seems to have a sort of organism, and appears like a congeries of pellicles stretched over one another, which form a kind of nervous compages.

Polypuses are often found upon opening the bodies of persons dying apoplectic; and are doubtless frequently the occasion of sudden death. They are seldom discovered till they have dispatched the patient.

It is, however, a dispute among physicians, whether *polypuses* be produced any considerable time before, or always immediately after death? Mr. Gould has an express discourse in the Philosophical Transactions to evince the former.

POLYPUS *of the lungs*. In the Philosophical Transactions, Dr. Robert Clarke gives us a very odd instance of a patient who coughed up, at times, several hundred *polypuses of the lungs*.

They seemed to have some organization, and were all perfectly alive. The patient said, though they had no life, he had frequently pressed a slimy matter out of the body of them.

Dr. Lister observes, that such *polypuses* are formed in the remotest and deepest branches of the aspera arteria, whence they are very difficult to get up. The patient above mentioned never brought them up till after a continued coughing of half a day and night.

He adds, that they are nothing but viscous excretions of the small glands, hard baked in those parts where form they receive. M. Buillieres observes, they are frequently mistaken for pieces of the blood-vessels or lungs.

Though Kerkringius, and others, have endeavoured to explode the notion of the formation of true *polypi* in the heart and blood-vessels, yet Malpighi, Bartholine, Tulpius, Pecklin, and others, have given us incontestible instances of the existence of true *polypi* in the heart, in the strictest sense; and we have three unquestionable evidences of the like nature, in Philos. Transact. N° 464. sect. 6.

POLYPYRENEOUS *fruits*, in *Botany*, are such as contain several kernels or seeds.

They are thus called from the Greek πολυς, *multi*, and σπερμα, *kernel*, or *berry*.

POLYSACTINODOS, in *Natural History*, a name given by Linkius, and some other authors, to those ſtar-fiſh whoſe body is divided into more than five rays, that being the more uſual and general number.

POLYSCHIDES *ſucus*, a ſea-plant, called in Engliſh *ſea-hanger*. It is one of the largeſt ſea-plants we know, growing often to ten feet or more in length. Its root is not flat in the manner of moſt of the other ſea-plants, but is compoſed of ſeveral little hooks, all which lay faſt hold of the ſtone on which it grows: theſe, in ſome meaſure, reſemble the tendrils of the vine, and are ſomewhat broad and flatted at the end, where they are faſtened to the ſtone, though round elſewhere, and are about half an inch long: theſe hooks grow from a broad flatiſh part at the bottom of the ſtalk, which is often four or five inches in diameter, and is uſually hollow, being compoſed only of two membranes conſiderably tough and firm, with a cavity between them; from the centre of this riſes the ſtalk, which is often twiſted and undulated at the edges; from the top of this ſtalk grows the leaf, which is divided into eight or ten ſegments; each of which is often again divided into two. Theſe ſegments are very long; and as the plant floats in the water, give it much of the appearance of a broad piece of leather cut into ſeveral thongs; theſe all terminate in ſharp points, and their colour is a brownish green. The aideſt eye cannot diſtinguiſh the leaſt nerve or fibre, either in the ſtalk or leaf of this plant; but on great numbers of theſe plants, that curious enquirer, M. Reaumur, found flowers of the ſame kind with thoſe which he originally diſcovered on the common ferns; they are compoſed of ſlender filaments, not exceeding the twentieth part of an inch in length; and theſe were the more eaſy to be overlooked, as they are of the ſame colour with the leaves of the plant. Thoſe plants on which M. Reaumur found theſe flowers, were not, however, entirely covered with them, but they ſtood at about a twelfth of an inch diſtance from one another. It was in the month of July that M. Reaumur examined this plant; and at that time there were no ſeeds diſcoverable upon it; but doubtleſs at a proper ſeaſon, and with proper care in the obſerver, they will hereafter be diſcovered as plainly in this as in many other of the ſea-plants, uſually ſuppoſed by authors to have wanted them. Mem. Acad. Par. 1712.

POLYSCOPE, a multiplying-glaſs, i. e. a glaſs which repreſents one object to the eye as if it were many; called alſo POLYHEDRON.

POLYSPASTON, πολυσπαστον, from πολυς, and σπαω, *trahe, I draw*, q. d. that may be drawn many ways, in *Mechanics*, a machine ſo denominated by Vitruvius, conſiſting of an aſſemblage of ſeveral pullies, uſed for raiſing of heavy weights in a little time.

The multiplication of pullies in the *polyſpaſton* is to very good purpoſe; it being demonſtrated in mechanics, that the force required to ſuſtain a weight by means of a *polyſpaſton*, is to the weight itſelf as unity to the number of ropes, or of the pullies, thoſe roper or pullies being ſuppoſed parallel to each other. See PULLEY.

Hence, the number of pullies, and the power, being given, the weight that will be ſuſtained thereby is eaſily found; viz. by multiplying the power by the weight. E. gr. Suppoſe the power 50 pounds, and the number of pullies 5, the weight they will balance is 250 pounds.

In like manner, the number of pullies being given, together with the weight ſuſtained, the power is found by dividing the weight by the number of pullies: thus, if the weight be 900 pounds, and the number of pullies 6, the power will be 150 pounds.

Doctules obſerves, that it is found by experience, that a moderate man, ſtanding barely on the ground, will lift 150 pounds; whence the ſame man, by means of a *polyſpaſton* conſiſting of 6 pullies, will be able to ſuſtain 900 pounds.

The power of the pullies will be ſtill exceedingly increaſed by joining ſeveral *polyſpaſtons*.

To find the number of pullies a *polyſpaſton* is to conſiſt of, to raiſe a given weight by a given power. Divide the weight by the power; the quotient is the number required. Suppoſe, e. gr. the weight 600 pounds, and the power 150; the pullies will be 4; whoſe diameters are to be all equal, ſuppoſing two of them upper, and two lower, moveable on the ſame common axes.

POLYSPERMOUS, πολυσπερμος, formed from πολυς, and σπερμα, *ſeed*, in *Botany*, is applied to ſuch plants as have more than four ſeeds ſucceeding each flower, without any certain order or number.

Theſe Mr. Ray makes a diſtinct kind of herbs, calling them *herbæ ſemine multi polyſperme*; where, by *ſemine multi*, are meant ſuch ſeeds as do not put off ſpontaneouſly the integuments or coverings which they either have, or appear to have, but fall off whole from the mother-plant.

Polyſpermous herbs are ſubdivided into, 1. Such as have a calyx or perianthium, conſiſting either, firſt, of *three leaves*, and the flower tripetalous, as the plantago aquatica, and the ſagittaria, both water-plants: or the flower polypetalous, and the calyx falling with it; as the chelidonium minus: or remaining after the flower is dropped; as in the hepatica nobilis. Secondly, of *five leaves*, in ſome deciduous, with the flower, as in the ranunculus; in others perennial, as in the helleborus niger ſeruleaceus; or annual, as in the flos Adonis. Thirdly, of *eight leaves*, as the malva and alcea. Fourthly, of *ten leaves*, as the caryophyllus, ſtigaria, pentaphyllum, tormentilla, argentina, althæa, and pentaphylloides.

2. Such as have no calyx or perianthium; as the clematitis, filipendula, ulmaria, anemone, nemorum, pulſatilla, &c.

POLYSTYLE *columnade*. See COLONNADE.

POLYSYLLABICAL *nihmes*, thoſe which repeat many ſyllables or words. See ECHO.

POLYSYLLABLE, πολυσυλλαβος, from πολυς, *much*, and συλλαβη, *ſyllable*, in *Grammar*, a word conſiſting of more than three ſyllables.

Stuckford refers the origin of *polyſyllables* in language to the confuſion of Babel; obſerving, that the languages which moſt probably aroſe about this time do remarkably differ from the moſt ancient Hebrew in words of a greater length than that of the original Hebrew words. The Chaldæan, Syrian, Egyptian, and Arabian languages, he ſays, afford inſtances of this kind, as well as the more modern tongues. Com. of the Sacred and Prophane Hiſt. vol. i. p. 136, &c.

POLYSYNDETON, πολυσυνδετον, in *Rhetoric*, a figure conſiſting in the union of the ſeveral parts of a ſentence by proper particles.

Such is, *Me pro cæteris & cæſi, & obſervat, & obligat.*

In oppoſition to this ſtands ASSYNDETON.

This figure adds a weight and gravity to an expreſſion, and makes what is ſaid to appear with an air of ſolemnity; and by retarding the courſe of the ſentence, gives the mind an opportunity to conſider and reflect upon every part diſtinctly. We often meet with this figure in Demoſthenes, which very well ſuits the gravity of his ſtyle. Thus he encourages the Athenians to proſecute the war againſt king Philip of Macedon, from this conſideration, that now *they had ſhips, and men, and money, and ſtores, and all other things, which might contribute to the ſtrength of the city, in greater number and plenty than in former times.* Philipp. iii.

POLYTHALAMIUM, in *Natural Hiſtory*, a name by which ſome authors have called the TURBI *marini concamerati*, a ſort of ſea-ſhell found frequently foſſile, with other ſhells, in Sweden, and brought over to us in the ſtones uſed for pavements, but not known in its recent ſtate.

It is of the ſame general ſtructure with the cornu ammonis, and thick nautilus, being compoſed of ſeveral cells or cavities, communicating with one another by means of a ſiphunculus or pipe; but it is uſually ſtraight, though ſometimes its end is twiſted exactly in the manner of the cornu ammonis.

POLYTHALAMIUS, in *Natural Hiſtory*, a term invented by Breynius, to expreſs a claſs of ſhells, the character of which is, that they are hollow ſhelly bodies, either ſtraight or regularly twiſted into a ſpiral form, always wide at the mouth, and growing narrower to the other extremity; they are divided within into ſeveral cells or chambers, which are called *thalami*, each ſeparated from the other by a diaphragm, or partition of ſhelly matter. The upper or largeſt chamber contains the body of the animal; but all the others are perforated by a ſiphunculus, which gives them communication one with another, and which runs from the mouth to the very apex, growing ſlenderer all the way.

Of this claſs he diſtinguiſhes four genera, the orthoceras, lituus, ammonites, and nautilus. The two laſt of theſe, he obſerves, have been long well known to the world; the two firſt he gives as new, and of his own diſcovery.

Of the orthoceratites, which are ſtones call in the ſhells of the orthoceros, there are at preſent diſtinguiſhed nine kinds: theſe differ from one another principally in the poſition of the ſiphunculus, or in their external form; the cone which they deſcribe running quicker or more gradually to a point; or, finally, by the thalami or chambers being wider or narrower.

POLYTHEISM, from πολυς, *much*, and θεος, *deus*, the doctrine or belief of a plurality of gods. See GOD, IDOLATRY, and JUPITER.

POLYTHRIX, the *hair-ſtone*, a name given by ſome wri-

ters

ters to those German agates which have received into their mass, while yet soft, either the branches of the conferva, or other capillary water-plants, or else have thin streaks of a ferrier matter frequent in them, and running in the form of hairs. See AGATE.

POLYTRICHUM, *golden maiden-hair*, in *Botany*, the name of a genus of mosses in the class of *cryptogamia*, the characters of which are these: the stalks are not much branched, and the capsules have calyptræ to cover them till mature; this calyptra is always hairy, and in many of the species is composed merely of long hairs, ranged lengthways together, without any membrane. The others have membranaceous calyptræ, but covered with erect hairs; the leaves of these kinds are rigid, and have a membranaceous appendage, by which they touch the stalks and surround them; those of the others are softer, and have not this appendage. The base of the pedicle which supports the head, is also in these surrounded by a sort of tube, round which there stand a number of membranaceous leaves; this is more visible in the larger than in the smaller species. The capsules in some of these mosses are square, in others they are roundish; and the square ones have usually an apophysis, by which they are joined to the pedicle, which the round ones never have, or at least very seldom. See *Tab.* XIV. *of Botany*, N° 12.

The *polytrichum* of the first order are those which have square capsules, which are joined to the pedicles by a round apophysis: of these there are three species.

The second order of the *polytrichum* comprehends those which have round capsules, and usually want the apophysis, by which the others are joined to the stalk. There are nine species of this kind. Dillen. Hist. Muse. p. 430. Linnæus enumerates three species.

Old writers are very full of the praises of this plant for its virtues in making the hair grow thick; but this seems to have been an opinion taken upon no better reason than the likeness of the stalks of the plant to hairs. They make a decoction of it in some parts of Germany, and wash the head carefully with it in the increase of the moon; but there is no great reason for supposing this liquor does any thing more than warm water would do. See ADIANTUM *aureum*.

POLYTROPHEROS, a name given by the Greeks to coarse bread, from its conveying much more nourishment to the body than the finer kind; which they called, by way of distinction, *oligotrophoteros*.

POLYZONOS, in *Natural History*, a name given by the ancients to a species of onyx, which had a dark or blackish ground, with a great number of white zones.

POMA, in the *Writings of the Old Greek Physicians*, a word which has given the commentators a great deal of trouble rightly to explain.

Brassavolus says, that it means all sorts of shelly or crustaceous coverings of fishes, but this is an absolute error; for even the medical authors do not extend its sense so far as that. The Greeks called all shells by the name *ostraca*, and this author attributing a different virtue to the whole shell of the purpura, sufficiently speaks this *poma* to have been but a part of it.

The Arabian writers were sensible of this, and rendered it by the words *asfor althoth*, which signify fragments like nails. Serapio calls it *mukatha*, which signifies a morsel or piece of any thing cut from a solid body. The original sense in which the Greeks used the word *poma*, was to express the thing that closed the mouth of any vessel with a long and narrow neck. The Latins expressed this by the word *operculum*, and sometimes, as in Sulpicius Severus, by the word *umbo*.

The ancients also used the word *poma* to express the lid or covering of a well, or of any hole. Now the purpuræ buccinæ, and all these other shells which the Greeks have called *strombides*, may in some sort be compared to narrow and deep vessels, and they have all of them a sort of *poma*; or, as the Latins have expressed it, an *operculum*, to stop the mouth of the shell, and prevent the ingress or egress of any thing at the creature's pleasure. This *operculum* being what Aristotle has called *epiclasmma*, is certainly also what Dioscorides means by the word *poma*; Aristotle has been very express in his description of it, and says that the tongue lies under it, and that all the *strombidæ* shells gave it. The *onyx Indicus*, therefore, was only the *poma*, or *operculum* of an Indian *strombida* shell, of the buccinum or purpura kind, and was of a sweet smell, and thence had the term *aromaticus*, or *odoratus*. The name *onyx* is easily accounted for, as the *poma* of every shell of this kind is flat and thin, and does not unapily resemble the human nail.

POMADA, an exercise of vaulting the wooden horse, by laying one hand over the pommel of the saddle.

POMATIA, in *Natural History*, the name of a large species of garden-snail, so called from its feeding on apples and other fruit. It is originally a native of Italy, but is become of late years so familiar with us in England, as if a native with us. It is a noble remedy in consumptive decays; and a person of distinction in England having occasion to take great numbers, had several large parcels brought carefully alive from Italy, and turned loose in his garden, where they multiplied to such a degree, that the neighbouring woods and hedges soon became full of them, and they have since been propagated in many other places.

The *pomatia* is much larger than our common snail, and of a paler colour: it is of a roundish figure, and has five spires or twists at the head: these are placed very close, and its mouth is large and almost circular, and has no duplicature or fold surrounding it, but is as thin as the rest of the shell.

POMATUM, or POMADO, a composition of apples, with lard and rose-water; used by way of unguent on many occasions, particularly for diseases of the skin, pimples, scurfs, &c. and to soften the hands, render the skin smooth, the complexion fresh, &c.

Pomatums are occasionally made with jessamine, orange, jonquils, tuberoses, &c. i. e. they are perfumed with the odours of those flowers.

The best is said to be that prepared of kid's grease, pippins, an orange sliced, with a glass of rose-water; and half a glass of white-wine, boiled and strained, and at last sprinkled with oil of sweet almonds.

Dr. Quincy observes, that the apple is of no significance at all in the recipe; and that the common *pomatum* sold in the shops is only lard beat into a cream, with rose-water, and scented with lemons, thyme, or the like.

The *pomatum* of the London Dispensatory is formed by beating tried, or purified lard with rose-water, in the proportion of three ounces of the water to two pounds of the lard, till they are well mixed; then melting it over a gentle fire, and after it has stood for a little while, that the watery part may settle, pouring off the lard, and incessantly stirring and beating it about till it grows cold, so as to reduce it into a light yielding mass; and afterwards adding so much essence of lemons as will be sufficient to give a grateful smell. Some scent it with oil of rhodium; and previously digest the lard for ten days with common water, renewing the water every day, a process which does not appear to be of much use. These ointments may be tinged of a fine red colour, for lip-salves, by a proper addition of alkanet root. The faculty of Paris directs, for this purpose, twenty-four parts of the white *pomatum*, eight of ox's marrow, and eight of white wax, cut in small pieces, to be melted together by the heat of a water-bath; one part, i. e. one fortieth of the whole mass, of powdered alkanet root to be added; the mixture stirred at times till it appears tinged of a deep red colour, and then strained through a linen cloth. Lewis.

POME, among *Gardeners*. To *pome*, is to grow or knit into a round head, somewhat like an apple.

Thus, they say, a *cabbage begins to pome*, &c. They sometimes use the term, *to cabbage*, in the same sense.

POMEGRANATE-*tree*, *punica*, in *Botany*, a genus of the *icosandria monogynia* class. Its characters are these: the empalement of the flower is bell-shaped, coloured, and cut into five parts at the top; the flower has five roundish, erect, spreading petals, which are inserted in the empalement, and a great number of slender stamina, which are also inserted in the empalement, terminated by oblong summits; the germen is situated under the flower, supporting a single style, crowned by a headed stigma; it afterward becomes a large almost globular fruit, crowned by the empalement; the fruit is divided into several cells by membranous partitions, which are filled with roundish succulent seeds. There are two species, including several varieties.

These plants grow naturally in Spain, Portugal, Italy, and Mauritania. There are also many of them in the West Indies, but they are supposed to have been transplanted there from Europe. They are so much improved there, as to be much preferable to any in Europe, the fruit being larger and finer flavoured.

The balaustia of the shops is the empalement of the flower of the double flowering *pomegranate*. Miller.

It is denominated from the abundance of its grains or kernels; q. d. *pomum granatum*, a *kernelled apple*; or from the country where it was anciently produced, viz. Granada.

The trees never grow high; their branches are a little prickly; their leaves are long and narrow; the flowers are of a deep red, and pentapetalous, set in bell-shaped cups of the same colour; and their fruit, which is composed of a great number of red angular grains, sometimes sweet, sometimes sour, and sometimes vinous, according to the quality of the tree, are all inclosed in little di-

finest cells, and covered, in common, with a thick brownish rind. Over this grows a kind of covering, of the same nature with the rind, formed of a production of the calyx.

In the general, *pomegranates* are not only agreeable to the taste, but good for the stomach, and of considerable use in medicine. Of the kernels are made syrups and conserves; and the peel or rind, which is called *malicorium*, is moderately astringent, and is an ingredient in several remedies and ptisans, for dysenteries, diarrhœas, hemorrhoids, hæmorrhages, and relaxations of the gums. The ancients used the rind as the moderns do sumach, in the preparation of leather.

The rind ought always to be dried, after the grains are taken out; that dried without scooping always tastes mouldy, and being more likely to increase distempers than cure them.

As to the conserve, there is but little of the true sort; it being very difficult to make. That which ordinarily passes for it is only sugar melted down, to which they give the colour, and sharp taste, with cochineal, cream of tartar, and alum.

POMELS, in *Heraldry*, are green roundles; so called by the English heralds, who express different coloured roundles by different names.

The French, who content themselves to denote the different colour of the roundles, call the *pomeis*, *fourmeaux cert*.

POMERIUM, in *Antiquity*. See POMŒRIUM.

POMIFEROUS, *apple-bearing*, in *Botany*, a name given to those plants which have the large fruit, covered with a thick hard rind; by which they are distinguished from the baccíferous, which have only a thin skin over the fruit.

The *pomiferous* kind have a naked monopetalous flower, divided into five partitions, and growing on the top of the succeeding fruit. They are divided into

1. *Coperulate*, or those creeping along the ground, &c. by means of tendrils; as the cucurbita, melo, cucumis, cepo, ballaimina, anguria, and crocyntha.

2. Without *cupreoli*, or *tendrils*, as the cucurbita elypeata, or melo cepo clypeiformis.

POMIGLION is a name given by foamen to the CANNON, or hindmost kind of a cannon. See GUN.

POME, or POMMETTE, in *Heraldry*. A *cross pomme*, or *pommette*, called also *trophy*, is a cross with a ball or knob, like an apple, at each end.

POMMEL, or POMMEL, in the *Manege*, a piece of brass, or other matter, at top, and in the middle, of the saddle-bow, to which are fastened the holsters, stirrup-leathers, &c.

POMMEL is also a round ball of silver, steel, or the like, fixed at the end of the guard and grasp of a sword; to serve, in some measure, as a counterpoise.

Baluze observes, that there are still extant charters and privileges granted by Charlemagne, which were sealed with the *pommel* of his sword, which, ordinarily, he promises to defend with the same sword.

POMMETTE. See POME.

POMŒRIUM, among the Romans. Authors are not agreed as to particular circumstances relating to the *pomœrium*: some will have it to be a piece of ground without the walls; others a space within them; and others again think it was both within and without. But which ever of these is true, the *pomœrium* was a place esteemed sacred, and kept free from houses and every other kind of obstruction. Hist. Acad. Inscr. vol. ii. p. 91, seq.

POMONA, in *Mythology*, an amiable nymph, for whose favour the deities of the fields were competitors. The name was originally appropriated to some person who had merited divine honours by the culture of fruit-trees, and especially of apple-trees. This nymph is represented as sitting on a large basket full of fruit, holding a number of apples in her left hand, and in the right a nosegay of flowers. At Rome she had a temple and altars. Her priest was called *Flamen Pomonalis*, and sacrifices were offered to her for the preservation of the fruits of the earth.

POMPEION, Πομπειον, in *Antiquity*, a stately edifice at Athens, in which were kept the sacred utensils made use of at festivals, and all things necessary for the solemn processions prepared. It stood at the entrance of the old city, which looked towards Phalerum, and was adorned with many statues of the Athenian heroes.

The word *pompeion* is derived from πομπευω, *cum pompa incedo*, and was likewise used for any utensil employed on these occasions.

POMPEY's *pillar*. See PILLAR.

POMPHOLYX, Πομφολυξ, literally denoting a *bubble or string on water*, in *Pharmacy*, a sort of metalline flowers, being a white, light, and friable substance, found adhering to the lid or cover of the crucibles or furnaces, wherein zinc or its ore are melted with other metals.

It is esteemed detersive and deliccative, though only applied externally.

The apothecaries sometimes call it *nix*, or *nihil album*, and sometimes *white tutty*, in regard of its resemblance to TUTTY in virtue.

POMPILUS, in *Ichthyology*, the name of a sea-fish, in the Linnæan system a species of the COBYPHENA, remarkable for following the ridders of ships to vast distances. It has no scales; it has a very broad line from the gills to the tail, under which are a number of dotted transverse lines, reaching to the belly, above the line on the side; the back is spotted with different colours; the mouth is moderately large, but the teeth very small; its forehead, between the eyes, is of a gold colour, and it has four fins, two at the gills, and two on the belly, and beside these, one long one running all the length of the back, and another answering it from the anus to the tail; its tail is not forked.

PAMPILUS is also used by some authors for the nautilus, as well as the papyraceous and the cameretted kind.

POMPION, in *Botany*. See PUMPKIN.

POMPONA, a name given by the Spaniards in America to a sort of *vanilla*, the pods of which are shorter and thicker than those of the common kind, and of a stronger smell, though less agreeable. The pulpy matter also in these pods is more liquid than that in the common kind, and the seeds much larger, being as big as those of mustard. This is never brought to market alone; but the Indians who gather it, cunningly mix it among the right kind, but this should be taken care of by the buyer, since this kind is very prejudicial, occasioning violent head-aches in men, and in women vapours and disorders of the womb.

It is not yet certainly known whether this be the fruit of a different species of the *vanilla* plant, or whether it be only different from the common in size, or in the place of growth of the plant.

POMUM, *apple*, a well known fruit. See APPLE-*tree*.

POMUM, *apple*, in *Botany*, is a fleshy or pulpy PERICARPIUM without valves containing a capsule.

POMUM *Adami*, in *Anatomy*, a prominence in the forepart of the throat. See ADAM'S *apple*.

POND, in *Geography*, a little lake, which neither receives nor emits its waters into any river.

POND, *fish*. See FISH-*pond*.

POND-*weed*, *potamogeton*, in *Botany*, a genus of plants of the *tetrandria tetragynia* class, the characters of which are these: the flower has no calyx or cup, but is composed of four obtuse, roundish, hollow, and open petals, which fall off before the ripening of the seeds; the filaments are four plane, obtuse, and very short filamentæ; the antheræ are double and short; the pistillum has four germina, which are all oval and pointed; these have no style, but obtuse stigmata; there is no other fruit than four seeds succeeding each flower; these are of a roundish, but flatted figure, gibbose, and pointed. Linnæus enumerates twelve species.

POND *weed*, *water*. See PEPLIDARIA.

POND *weed*, *triglit headed*. See ZANNICHELLIA.

PONDERATE, in our *Ancient Customs*, a method of curing sick children, by weighing them at the tomb of some saint; counterpoising or balancing the scale with money, wheat-bread, or any other thing the parents were willing to offer to God, his saints, or the church.

But a sum of money was always to make part of the counterbalance. By this means the cure was effected. *Ad sepulchrum sancti, summa se ponderabat.*

PONDUS, *weight*. See WEIGHT.

PONDUS, in *Ancient Records*, denotes a duty paid to the king, according to the weight of merchandizes.

PONDUS *regis*, the Rainland weight anciently appointed by the king; being that which we now call *troy-weight*. See STANDARD and TROY-WEIGHT.

Ad PONDUS *emunas*. See AD.

PONDUS, *temperamentum ad*. See TEMPERAMENTUM.

PONE, a writ, whereby a cause depending in the county, or other inferior court, is removed to the common pleas, or sometimes to the king's bench.

PONE *per vadium*, is a writ commanding the sheriff to take surety of one for his appearance at a day assigned.

PONENDUM *in ballivam*, in *Law*, a writ commanding that a prisoner be *bailed*, in cases bailable.

PONENDUM *billam et exceptiones*, a writ by which bailiffs are required to put their seals to *exceptions* exhibited by the defendant against the plaintiff's evidence, verdict, or other proceedings before them, according to stat. Westmin. 2.

PONENDIS *in assisis*, a writ granted by the statute of Westmin. 2. cap. 38. which statute shews what persons sheriffs ought to impanel upon *assises* and juries, and what not.

PONGA, in *Botany*, H. M. *Arbor minor foliosa in Malabaria*. D. Commelin *totius Brasiliæ* Piso *similis*,

a tall evergreen tree growing in Malabar, and bearing no observable flowers; the fruit adheres to the branches in the same manner as that of the jaca; and hence the Portuguese call the tree the wild jaca; the calyces are echinated, first green, and afterward reddish, and contain multitudes of roundish, oblong, acuminated, and reddish seeds.

A cataplasm prepared of the green fruit of the tree bruised, being applied to tumors, promoter their suppuration. Of the bark and root, boiled in water, is prepared a fomentation for inflammatous tumors of the legs; an endemic disease among the Indians, and called by the Portuguese pedo St. Thome, which preserves them from an inflammation. Raii H. P.

PONGO, in *Zoology*, a name given in Purchas's Pilgrims to the ORANG-outang.

PONIARD, formed from the French *poignard*, and that from *poignis*, *hand-ful*, a little pointed dagger, very sharp-edged; borne in the hand, or at the girdle, or hid in the pocket.

The *poniard* was anciently in very great use; but is now in good measure set aside, except among ASSASSINS.

Sword and *poniard* were the ancient arms of duellists; and are said to continue still to among the Spaniards.

The practice of sword and *poniard* still makes a part of the exercise taught by the masters of defence.

PONS *varoli*, or *cerebelli*, or PONS *cerebri*, in *Anatomy*, the upper part of a duct in the third ventricle of the brain, situate in the cerebellum, and leading to the infundibulum. *See Tab. Anat. (Osteol.) fig. 5. litt. g g.*

It is thus called from its discoverer, Varolius, a Italian physician, who flourished in the university of Padua about the year 1572.

PONTAGE, *pontagium*, a contribution towards the maintenance, repairing, and rebuilding, of BRIDGES.

This was anciently one of the three general national charges, whence no person of any degree whatever was exempted.

The three things called *trinoda necessitas*, whence, Ingulphus tells us, *nulle possunt lauari*, were, the expedition to the wars, the building of castles, and the building and repairing of bridges. Mr. Selden, in his notes on Eadmerus, observes, that *ne eandem episcopi, abbates, & monachi, immunes erant.* And Matt. Paris adds, anno 1244, that in all grants of privileges to the monasteries, those three things were always excepted, for the public good, and that the people might be better able to resist any enemy.

PONTAGE is also a due anciently belonging to the lord of the fee, for persons or merchandizes, that pass over rivers, bridges, &c. called in the later Latin *pontagium*, or *pontuagium*, pontage.

PONTAGIA, a term used by Paracelsus, and his followers, to express a mixing saline substances with those which are bitter or typtic.

PONTEE, in the *Glass Trade*, an iron instrument used to fix the GLASS at the bottom, for the more convenient fashioning the neck of it.

PONTEE-*rods*, in *Glass Making*, is the iron whereon the under servants place the irons from the upper workmen, when they have knocked off the broken pieces of glass.

PONTEDERIA, in *Botany*, a genus of the *hexandria monogynia* class. Its charathers are these: the flowers are included in an oblong sheath, which opens on one side; it hath six petals, which are divided; the three upper are erect, and form a kind of lip; the three under are reflexed; it hath six stamina, which are inserted to the petals; the three which are longest are fastened to the mouth of the tube; the other are inserted in the base; they are terminated by prostrate summits; under the petals is situated an oblong germen, supporting a single style, which declines, and is crowned by a single stigma; the germen afterward turns to a soft fruit, divided into six cells, each containing several small roundish seeds. There are two species. Miller.

The characters, according to Linnæus, are, that the flower has a single petal, divided into six parts, forming a double lip; three of the stamina are inserted in the apex, and three in the tube; and the fruit is a three-celled capsule. He enumerates three species.

PONTIBUS *reparandis*, a writ, directed to the sheriff, commanding him to charge one or more person to repair a bridge, to whom it belongs.

PONTICA *gemma*, a name given by the ancients to a stone of the AGATE kind, with a white ground and red and black spots, irregularly placed, and making a beautiful variegation in it. This seems to have been the same stone which some of the moderns have called the *small-pox stone*, from its spots resembling the eruptions in that disease. The ancients mention several kinds of it, as they were spotted with various colours.

PONTICA *vina*, a term used to express acid, feculent, and tartarous wines.

PONTICUM *mel*, a name given to a sort of poisonous honey.

PONTICUS *mus*, in *Zoology*, the name of a creature described by the ancients, and supposed to be the same with our SQUIRREL.

PONTIFEX, *pontifex, high-priest*, a person who has the superintendance and direction of divine worship; as the offering of sacrifices, and other religious solemnities.

The Romans had a college of *pontifs*, and over those a sovereign *pontif*, or *pontifex maximus*, instituted by Numa; whose function it was to prescribe the ceremonies with which each god was to be worshipped, compose the rituals, direct the Vestals, regulate the calendar, and settle the several games, and assist at them; and for a good while to perform the business of augury; till on some superstitious occasions he was prohibited intermeddling therewith.

He consecrated the statues of the gods, before they were put up in the temples; conducted the dedications of the temples; offered sacrifices; blessed the figures of some of JOVE's thunderbolts, to preserve the people from harms; and compiled their statutes.

The Jews too had their *pontif*, or high-priest; and among the Romanists, the pope is still styled the *sovereign pontif*.

Authors differ about the origin of the word *pontifex*. Some derive it from *posse facere*, that is, from the authority the *pontifs* had to sacrifice; others, as Varro, from *pons*, because they built the Sublician bridge, that they might go and offer sacrifice on the other side of the Tiber.

PONTIFICAL, *Pontificale*, a book of the rites and ceremonies belonging to pontifs, bishops, popes, &c. See RITUAL, and CEREMONIALE.

PONTIFICAL *college*, in *Roman Antiquity*, consisted of those who had the principal direction of the affairs of religion, who settled religious disputes, regulated the worship and ceremonies, and explained the mysteries of religion. This college, at the time of its first institution by Numa, was composed of four priests selected from the patricians, to whom were afterwards added four others from the plebeians. Sylla the dictator increased their number to fifteen, of whom eight were superior, and seven subordinate; and the chief among them assumed the title of PONTIFEX *maximus*.

PONTIFICALIA, the robes and ornaments wherein a bishop performs divine service.

PONTIFICATE, *pontificatus*, the state or dignity of a pontif, or high-priest.

Cæsar reformed the CALENDAR in the time of his *pontificate*.

PONTIFICATE is more peculiarly used in modern writers for the reign of a pope.

The concordat was passed in the *pontificate* of Leo X.

There was a *pontificate* that only lasted twenty-four hours.

PONTLEVIS, in the *Manege*, a disorderly rebelling action of a horse, in disobedience to his rider; in which he rears up several times, and rises to upon his hind legs, that he is in danger of coming over. It is cured by clapping spurs smartly to him, as the fore-feet are returning to the ground.

PONTOON, in *Naval Language*, denotes a low flat vessel, resembling a lighter or barge of burthen, and furnished with cranes, capstens, tackles, and other machinery, necessary for careening ships of all sizes. These are very common in the principal ports of the Mediterranean, but rarely used in the northern parts of Europe. Falconer.

PONTOON, or PONTON, in *War*, denotes a kind of flat-bottomed boat, whose carcass of wood is lined within and without with tin. The French *pontons*, and those of most other powers, are covered on the outside with strong copper-plates, without any inside lining; and these have the advantage of iron's, because copper is much stronger than tin, and is not damaged by rust. Our *pontons* are twenty-one feet long, nearly five feet broad, and two feet 1½ inch deep within.

PONTOON-*bridge* is made of *pontons* slipped into the water, and placed about five or six feet asunder; each fastened with an anchor, when the river has a strong current, or to a strong rope, that passes across the river, and runs through the rings of the *pontons*. Each boat has an anchor, cable, hawser, and chests. The hawsers are about five or six inches square, and twenty-one feet long. The chests are boards joined together by wooden bars, about three feet broad, and twelve feet long. The hawsers are laid across the *pontons* at some distance from one another, and the chests upon them joined close. When several of these are thus connected, they form one firm, uniform bridge, by means of which a train of artillery, cavalry, infantry,

infantry, &c. may paſs over a river, arm of the ſea, &c. If *pontoons*, &c. are wanting, bridges are formed of empty casks or barrels, that ſupport baulks and planks. Cæſar and Aulus Gellius both mention *pontons*; but theirs were no more than a kind of ſquare flat veſſels, proper for the carrying over of horſe, &c. Ours, however, take their names from them: thoſe authors call them *pontones*, of *pons*.

POUTOON-*carriage* is made with two wheels only, and two long ſide-pieces, whoſe fore-ends are ſupported by a limber; and ſerves to carry the *pontoon*, boards, croſs-timbers, anchors, and every thing elſe neceſſary *for* making a bridge.

PONT-VOLANT, *flying-bridge*, a kind of bridge uſed in ſieges; made of two ſmall bridges laid over one another, and ſo contrived by means of cords and pullies placed along the ſides of the under-bridge, that the upper may be puſhed forwards, till it join the place where it is deſigned to be fixed; the whole length of both not to be above five fathom, leſt they ſhould break with the weight of the men. *See* BRIDGE.

POOD denotes a weight in Ruſſia, equal to forty of their pounds; and amounting to 35½ or 36 Engliſh pounds avoirdupoiſe.

POOL is properly a reſervoir of water, ſupplied with ſprings, and diſcharging the overplus by ſluices, defenders, weirs, and other cauſeways.

POOL, *mill.* See MILL.

POOL, *wharf.* See WHARF.

POOL-*finch*, in *Ornithology*, a name given in many parts of England to the red-ſhank.

POOP, in *Sea Language*, denotes the hind-part of a ſhip, or that wherein the helm is fixed; called alſo STERN. The *French* frequently call it *queue*, *tail*, becauſe the rudder here applied ſerves the ſame purpoſes in a ſhip as the tail does to fiſhes. The *poop* is divided into three or four ſtories, which all together form the *poop* caſtle, or hind-caſtle, the outſide of which is richly adorned with balconies, galleries, trophies, the arms of the prince, &c.

To have the wind in *poop*, in *Sea-phraſe*, is to have it behind, or favourable.

POOP, *puppis*, *puna*, denotes more particularly the higheſt or uppermoſt part of a ſhip's hull a-ſtern. See *Tab. Ship. fig.* 2. *lit.* P. See DECK.

POOP-*royal* is a ſhort deck or plat-form, placed over the aſtmoſt part of the *poop* in the largeſt of the *French* and *Spaniſh* men of war, and ſerving as a cabin for their maſters and pilots. This is uſually called the top-gallant-*poop* by our ſhip-wrights.

POOPING, in *Sea Language*, denotes the ſhock of a high and heavy ſea upon the ſtern or quarter of a ſhip, when ſhe ſcuds before the wind in a tempeſt. This circumſtance is extremely dangerous to the veſſel, which is thereby expoſed to the riſk of having her whole ſtern beat inwards, by which ſhe would be immediately laid open to the entrance of the ſea, and, of courſe, foundered, or torn to pieces.

POOR, *pauper*. A *poor* perſon, in a legal ſenſe, is one who is a burden to and charge upon a parith.

Formerly, the maintenance of the *poor* was chiefly an eccleſiaſtical concern; and a fourth part of the tithes in every parith was ſet apart for that purpoſe. Afterwards, when the tithes of many parithes were appropriated to the monaſteries, theſe ſocieties were the principal reſource of the *poor*, who were farther relieved by voluntary contributions. Judge Blackſtone obſerves, that till the ſtatute 26 Hen. VIII. cap. 28. he finds no compulſory method for providing for the *poor*; but upon the total diſſolution of the monaſteries, abundance of ſtatutes were made in the reign of king Henry VIII. Edw. VI. and Elizabeth, for this purpoſe. At length, by ſtat. 43 Eliz. *cap.* 2. OVERSEERS of the *poor* were appointed in every parith.

POOR-*rate*. By the 14 Eliz. cap. 5. power was given to the juſtices to lay a general aſſeſſment; and this hath continued ever ſince. For by 43 Eliz. cap. 2. the church-wardens and overſeers of the *poor* of every parith, or the greater part of them (with the conſent of two juſtices, one of whom is of the quorum, dwelling in or near the parith), are empowered to raiſe weekly, or otherwiſe, by taxation of every inhabitant, parſon, vicar, and other, and of every occupier of lands, houſes, &c. materials for employing the *poor*, and competent ſums for their relief. Notice ſhall be given in church of every ſuch rate the next Sunday after it is allowed, which may be inſpected by every inhabitant, paying 12. and copies of it granted on demand, 6*d.* being paid for every twenty-four names; and a churchwarden or overſeer refuſing, ſhall forfeit 20*s.* to the party aggrieved. The rate is to be levied by diſtreſs on thoſe who refuſe to pay it; and appeals againſt it are allowed. 17 Geo. II. cap. 2. cap. 38. See OVERSEERS.

If the juſtices find, that the inhabitants of any parith are not able to levy among themſelves ſufficient ſums for the purpoſes ſpecified in the act, they may aſſeſs any other parith within the hundred; and if the hundred be unable to grant neceſſary relief, they may rate and aſſeſs any parith in the county. 43 Eliz. cap. 2. Concerning the obligation of parents and children, ſee PARENT and CHILD.

In order to compel huſbands and parents to maintain their own families, the law hath provided, that all perſons running away out of their parithes, and leaving their families upon the parith, ſhall be deemed and ſuffer as incorrigible rogues. 7 Jac. cap. 4. And if a perſon merely threatens to run away and leave his wife and children upon the parith, he ſhall, upon conviction, before one juſtice by confeſſion, or oath of one witneſs, be committed to the houſe of correction, for any time not exceeding one month. 17 Geo. II. cap. 5. For the farther maintenance of the *poor*, there are many fines and forfeitures payable to their uſe; as for ſwearing, drunkenneſs, deſtroying the game, &c. And alſo parts of waſtes, woods, and paſtures, may be incloſed for the growth and preſervation of timber and underwood for their relief. See WOOD-*land*.

POOR, *ſettlement and removal of the*. The firſt rudiments of parith ſettlements ſeem to be the ſtatutes 12 Ric. II. cap. 7. & 19 Hen. VIII. cap. 12. which direct the *poor* to abide in the cities or towns where they were born, or ſuch wherein they had dwelt for three years, a term afterwards (viz. by 39 Eliz. cap. 4.) confined, in the caſe of vagabonds, to one year only. But after the Reſtoration, by 13 & 14 Car. II. cap. 12. a legal ſettlement was declared to be gained by birth; or by inhabitancy, apprenticeſhip, or ſervice for forty days; within which period all intruders were made removeable from any parith by two juſtices of the peace, unleſs they ſettled in a tenement of the yearly value of 10*l.* The frauds, naturally conſequent upon this proviſion, which gave a ſettlement by ſo ſhort a reſidence, produced the ſtatute 1 Jac. II. cap. 17. which directed notice in writing to be delivered to the parith-officers, before a ſettlement could be gained by ſuch reſidence. Subſequent proviſions allowed other circumſtances of notoriety to be equal to ſuch notice given; and thoſe circumſtances have from time to time been altered, enlarged, or reſtrained, whenever the experience of new inconveniences, ariſing daily from new regulations, ſuggeſted the neceſſity of a remedy. And the doctrine of certificates was invented, by way of counterpoiſe, to reſtrain a man and his family from acquiring a new ſettlement by any length of reſidence whatever, unleſs in two particular excepted caſes; which makes parithes very cautious of giving ſuch certificates, and of courſe confines the *poor* at home, where frequently no adequate employment can be had. The law of ſettlements may be, therefore, now reduced to the following general heads; or a ſettlement in a parith may be acquired, 1. By *birth*; for wherever a child is firſt known to be, that is always *prima facie* the place of ſettlement, until ſome other can be ſhewn. This is alſo always the place of ſettlement of a baſtard child; for a baſtard having in the eye of the law no father, cannot be referred to *his* ſettlement, as other children may. However, this rule admits of ſeveral exceptions; as in the caſe of a baſtard born in a place by colluſion; after the order of removal is made out; in removing; after the removal, and before the appeal; in a ſtate of vagrancy; in a priſon; in a lying-in hoſpital; and under a certificate. But with regard to legitimate children, though the place of birth be *prima facie* the ſettlement, yet it is not concluſively ſo; for there are, 2. Settlements by *parentage*, being the ſettlement of one's father or mother; all children being really ſettled in the parith where their parents are ſettled, until they get a new ſettlement for themſelves. A new ſettlement may be acquired ſeveral ways; as, 3. By *marriage*: for a woman, marrying a man that is ſettled in another parith, changes her own; the law not permitting the ſeparation of huſband and wife. But if the man has no ſettlement, her's is ſuſpended during his life, if he remains in England, and is able to maintain her; but in his abſence, or after his death, or during (perhaps) his inability, ſhe may be removed to her old ſettlement. The other methods of acquiring ſettlements in any parith are all reducible to this one, of *forty days reſidence* therein; but this forty days reſidence (which is conſtrued to be lodging or lying there) muſt not be by fraud, or ſtealth, or in any clandeſtine manner, but accompanied with one or other of the following concomitant circumſtances. The next method, therefore, of gaining a ſettlement is, 4. By forty days reſidence and *notice*. For if a ſtranger comes into a parith, and delivers notice in writing of his place of abode, and number of his family, to one of the overſeers (which

muſt

must be read in the church and registered), and resides there unmolested for forty days after such notice, he is legally settled thereby. 13 & 14 Car. II. cap. 12. 1 Jac. II. cap. 17. 3 & 4 W. & M. cap. 11. But there are also other circumstances equivalent to such notice: therefore, 5. *Renting* for a year a tenement of the yearly value of 10*l.* and residing forty days in the parish, gains a settlement without notice. 13 & 14 Car. II. cap. 12. 6. Being charged to and paying the public *taxes* and levies of the parish, excepting those for scavengers, highways, house, and windows. 9 Geo. I. cap. 7. 21 Geo. II. cap. 10. 18 Geo. III. cap. 26. And, 7. Executing, when legally appointed, any public parochial *office* for a whole year in the parish, as churchwarden, &c. are both of them equivalent to notice, and gain a settlement, if connected with a residence of forty days. 3 & 4 W. & M. cap. 11. 8. Being *hired* for a year, when unmarried and childless, and *serving* a year in the same service; and, 9. Being bound an *apprentice* for seven years, give the servant and apprentice a settlement without notice, in that place wherein they serve the last forty days. 3 & 4 W. & M. cap. 11. 8 & 9 W. III. cap. 10. 31 Geo. II. cap. 11. 10. Lastly, the having an *estate* of one's own, and residing thereon forty days, however small the value may be, in case it be acquired by act of law, or of a third person, as by descent, gift, devise, &c. is a sufficient settlement; but if a man acquire it by his own act, as by purchase (in its popular sense, in consideration of money paid), then, unless the consideration advanced, *bona fide*, be 30*l.* it is no settlement for any longer time than the person shall inhabit thereon. 9 Geo. I. cap. 7. All persons, not so settled, may be removed to their own parishes on complaint of the overseers, by two justices of the peace, if they shall adjudge them likely to become chargeable to the parish into which they have intruded; unless they are in a way of getting a legal settlement, as by having hired a house of 10*l.* per annum, or living in an annual service; for then they are not removeable. And in all other cases, if the parish to which they belong will grant them a certificate, acknowledging them to be their parishioners, they cannot be removed, because likely to become chargeable, but only when they become actually chargeable. But such certificated persons can gain no settlement by any of the means above mentioned, unless by renting a tenement of 10*l.* per annum, or by serving an annual office in the parish, being legally placed therein: neither can an apprentice or servant to such certificated person gain a settlement by such their service. 8 & 9 W. III. cap. 30. 12 Ann. cap. 18. These are the general heads of the laws relating to the *poor*, which, by the resolutions of the courts of justice thereon, within a century past, are branched into a great variety. And yet notwithstanding the pains that have been taken about them, they still remain very imperfect, and inadequate to the purposes for which they are designed. Blackst. Comm. book i. p. 360, &c. For a variety of cases and arguments relating to the settlement, removal, &c. of the *poor*, see Burn's Justice, art. *Poor*.

POOR, or POWER, in *Ichthyology*, a name given by the people of Cornwall to a species of bearded gadus. This is the GADUS *minutus* of Linnæus, and is the only species of cod-fish with three dorsal fins that is found in the Mediterranean sea. It is taken in great quantities near Marseilles, and esteemed good, but incapable of being salted or dried. Its length is little more than six inches.

POOR *man's pepper*, in *Botany*. See DITTANDER.

POOSPANSCUM, in *Natural History*, the name of a peculiar species of fossil in the East Indies. It is of the nature of the blende, or mock-lead, with us; but it is not formed into so large flakes, but more resembles the steel-grained lead ores. It is found in the beds of rivers, and when calcined, it is used with the juices of certain herbs, for ulcers and other cutaneous disorders. Before calcination it is also used by the women to make their hair of a fine glossy black colour, which it performs very neatly.

POPÆ, among the Romans, were such persons as attended the sacrifices, whose business it was to provide victims, and to kill them after they had knocked them down. They were half naked, their shoulders, arms, and upper parts of their bodies being uncovered as far as their navels, and the rest covered to the mid-leg with a linen apron, or the skins of the sacrifices; and they wore crowns of laurel upon their heads. See SACRIFICE.

POPE, *papa*, i. e. *universal father*, the bishop of Rome; being the head or patriarch of the Roman catholic church. Father le Cointe, in his Annals, observes, from St. Jerom, St. Cyprian, St. Gregory, St. Augustine, and Sidonius Apollinaris, that the title *pope* was anciently given to all bishops. Accordingly we find, that in the eighth general council held at Constantinople, in the year 869, which was composed of three hundred bishops, all the patriarchs were there called *popes*.

Bishops were also addressed under the term *bishops*, and *beatitude*; and their churches were called *episcopal sees*. He adds, that it was only in the eleventh century, that Gregory VII. first appointed, in a synod held at Rome, that the title *pope* should be restrained to the bishop of Rome, as a particular distinction and prerogative.

It is one of the maxims of Gregory, contained in a famous piece, entitled Dictatus *Papæ*, that there is no name in the world but his, i. e. as some understand it, he alone is to be styled *pope*; and F. Paul observes, that the name of *pope*, formerly common to all bishops, was appropriated by Gregory VII. to the Roman pontif.

In the council of the Lateran, held under Innocent III. the *pope* was declared *ordinary of ordinaries*.

The power of the *pope* has advanced by slow degrees to that plenitude in which it has been exercised in later times. It appears, that towards the end of the third century, the bishop of Rome, in common with those of Antioch and Alexandria, had a kind of pre-eminence over all others, because they were considered as rulers of primitive and apostolic churches. However, this pre-eminence implied no superior power and authority, infringing on the rights and liberties of other bishops, but merely a power of convening councils, of presiding in them, of collecting voices, and such other things as were essential to the order of those assemblies; a power similar to that which Cyprian, bishop of Carthage, possessed in the African churches. About the close of the fourth century, the bishop of Rome surpassed all his brethren in the magnificence and splendor of the church over which he presided; in the riches of his revenue and possessions; in the number and variety of his ministers; in his credit with the people, and in his sumptuous and splendid manner of living. Nevertheless it is certain, that at this time the bishops of that city had not acquired the pre-eminence of power and jurisdiction in the church, which they afterwards enjoyed. Differences in religion were ultimately decided, and ecclesiastical laws were enacted either by the emperor or by councils; nor does it appear, that any of the bishops acknowledged, that they derived their authority from the permission and appointment of the bishop of Rome, or that they were exempt bishops by the favour of the apostolic see. But in this century we may trace, in the imprudence of the emperors, the dexterity of the Roman prelates themselves, and the inconsiderate zeal and precipitate judgment of certain bishops, several of those steps by which they afterwards ascended to the summit of ecclesiastical power and despotism. The law of Valentinian in 372, which empowered the bishop of Rome to examine and judge other bishops, that religious disputes might not be decided by profane and secular judges, approved and confirmed in a council at Rome in 378, proved very favourable to the ambition and advancement of the Roman pontif; and his votaries have likewise laid great stress on the fourth canon of the council held at Sardis, in 347, which prohibited the election of a successor to a bishop deposed by neighbouring prelates, before the bishop of Rome had examined the cause, and pronounced sentence: but the authority of this council has been generally considered as extremely dubious, and its decrees have been regarded by many as altogether fictitious and spurious. In the fifth century a variety of circumstances united in augmenting the power and authority of the bishop of Rome; though he had not, as yet, assumed the dignity of supreme law-giver and judge of the whole Christian church. The bishops of Alexandria and Antioch, unable to make head against the lordly prelate of Constantinople, fled often to the Roman pontif for succour; and the inferior order of bishops used the same method, when their rights were invaded by those prelates. The protection afforded them by the Roman pontif was the means of extending his dominion in the East, and of imperceptibly establishing his supremacy. In the West its increase was owing to other causes: the declining power, and the supine indolence of the emperors, left the authority of the bishop who presided in their imperial city almost without control. The incursions, moreover, and triumphs of the barbarians contributed to its advancement; for the kings, who penetrated into the empire, when they perceived the subjection of the multitude to the bishops, and the dependence of the bishops upon the Roman pontif, resolved to reconcile this ghostly ruler to their interests, by loading him with various kinds of honours and benefits. However, the Africans could not be prevailed upon, by threats or promises, to submit the decision of their controversies, and the determination of their causes, to the Roman tribunal. Although the Roman pontifs artfully availed themselves of every circumstance

cumſtance that could contribute to their obtaining univerſal dominion, yet it is certain, that towards the cloſe of the ſixth century, the emperors and the nations in general were far from being diſpoſed to bear with patience the yoke of ſervitude, which the ſee of Rome was arrogantly impoſing upon the Chriſtian church. The Gothic princes ſet bounds to the power of the biſhop of Rome in Italy, permitted none to be raiſed to the pontificate without their approbation, and reſerved to themſelves the right of judging concerning the legality of every new election. They enacted ſpiritual laws, called the religious orders before their tribunals, and ſummoned councils by their regal authority.

In the beginning of the ſeventh century, or about the year 606, Boniface III. as Baronius relates, engaged the emperor Phocas to take from the biſhop of Conſtantinople the title of œcumenical or univerſal biſhop, and to confer it upon the Roman pontifs; and thus, as it is ſaid, introduced the papal ſupremacy. But the ambitious views of the biſhops of Rome were ſtill vigorouſly oppoſed, not only by ſeveral emperors and princes, but alſo by whole nations; and the civil magiſtrate retained his influence in religious matters, and the Roman pontifs were obliged to acknowledge their ſubordination to the regal authority. No event ſeems to have been more favourable to their ambitious views than the part they took in the eighth century, in promoting the advancement of the traitor Pepin to the throne of Childeric III. in anointing and crowning him as king of France. This proved an abundant ſource of opulence and credit to the church, and to its aſpiring miniſters; for Pepin, having obtained two victories over Aiſtulphus, king of the Lombards, in 754 and 755, compelled him to deliver up to the ſee of Rome the exarchate of Ravenna, Pentapolis, and all the cities, caſtles, and territories, which he had ſeized in the Roman dukedom. And thus the biſhop of Rome was raiſed to the rank of a temporal prince. The grant of Pepin was afterwards confirmed by his ſon Charlemagne, who alſo ceded to the Roman pontifs ſeveral cities and provinces in Italy, which were not contained in his father's grant; reſerving to himſelf the ſupreme dominion. It is ſaid that a pretended grant of Conſtantine the Great was made uſe of both by Adrian I. and Leo III. in order to perſuade Charlemagne to this donation. At this time the power of the *pope* was ſubordinate to that of the emperors, and confined within very narrow limits. The right of election was veſted in the emperor, and his approbation was neceſſary to the conſecration of the biſhops of Rome. However, their authority and affluence greatly increaſed from the time of Lewis the Meek, and more eſpecially from the acceſſion of Charles the Bald to the imperial throne. Their power was augmented in a very conſiderable degree by the diviſions and troubles that aroſe in the empire towards the cloſe of the ninth century: the emperors were diveſted of their eccleſiaſtical authority, the power of the biſhops was greatly diminiſhed, and even the authority of both provincial and general councils began to decline. The Roman pontifs availed themſelves of various circumſtances that occurred at this time to promote an opinion, that the biſhop of Rome was conſtituted by Jeſus Chriſt ſupreme legiſlator and judge of the church univerſal; and that, therefore, the biſhops derived all their authority from the Roman pontif, and that the councils could not determine any thing without his permiſſion and conſent. They had alſo recourſe to forged memorials, acts of councils, and epiſtles, in order to eſtabliſh their claims to ſupremacy. The moſt notorious forgeries of this kind were the DECRETAL epiſtles, compiled by an obſcure writer, but aſcribed, in order to give them credit, to Iſidore, biſhop of Seville. In the tenth century a novel doctrine was propagated by ſome mercenary and intereſted prelates, who publicly maintained, that the Roman pontifs were not only biſhops of Rome, but of the whole world; and that their authority, though divine in its origin, was conveyed to them by St. Peter, the prince of the apoſtles. The CRUSADES of the eleventh century very much contributed to the augmentation of the influence and authority of the Roman pontifs; ſo that towards the cloſe of this century they ſeem to have attained the zenith of their dominion. From the time of Leo IX. the *popes* employed every method, which the moſt artful ambition could ſuggeſt, to render their dominion both deſpotic and univerſal. They not only aſpired to the character of ſupreme legiſlators in the church, to an unlimited juriſdiction over all ſynods and councils, whether general or provincial, to the ſole diſtribution of all eccleſiaſtical honours and benefices, as divinely authoriſed and appointed for that purpoſe, but they carried their inſolent pretenſions ſo far as to give themſelves out for lords of the univerſe, arbiters of the fate of kingdoms and empires, and ſupreme rulers over the kings and princes of the earth. Gregory VII. ſeems to have exceeded all his predeceſſors in the luſt of dominion, as well as in the ſucceſs which attended his endeavours to obtain it. He conſidered the Roman pontif, under the character of Chriſt's vicegerent, as the king of kings, and the whole univerſe as his rightful domain. Accordingly, with an arrogance hardly to be paralleled, he claimed tribute from France, Saxony, Spain, England, the moſt powerful of the German princes, Hungary, Denmark, Poland, &c. ſoliciting them to do homage to the Roman ſee, to make a ſolemn grant of their kingdoms and territories to the prince of the apoſtles, and to hold them under the juriſdiction of his vicar at Rome, as fiefs of the apoſtolic ſee. If the ſucceſs of this pontif had been anſwerable to the extent of his inſolent views, all the kingdoms of Europe would have been this day tributary to the Roman ſee, and its princes the ſoldiers or vaſſals of St. Peter, in the perſon of his pretended vicar upon earth. Many of his attempts, however, were crowned with a favourable iſſue, and from the time of his pontificate the face of Europe underwent a conſiderable change, and the prerogatives of the emperors, and other ſovereign princes, were neceſſarily diminiſhed. In Italy his ſucceſs was the moſt remarkable; for he prevailed upon Mathilda, the daughter of Boniface, duke of Tuſcany, to ſettle all her poſſeſſions in Italy and elſewhere upon the church of Rome; and though the Roman pontifs have not been able to preſerve the whole inheritance, thus granted to them, they ſtill remain in the poſſeſſion of a conſiderable part of it. See ECCLESIASTICAL *ſtate*.

The monſtrous power of erecting new kingdoms, which had been claimed by the pontifs from the time of Gregory VII. was not only aſſumed, but exerciſed alſo by Alexander III. in a remarkable inſtance; for in the year 1179 he conferred the title of king, with the enſigns of royalty, upon Alphonſo I. duke of Portugal, who, under the pontificate of Lucius II. had rendered his province tributary to the Roman ſee. In the thirteenth century the ſame ambitious ſpirit governed the councils and proceedings of ſucceeding pontifs; and they were induſtrious in inculcating the maxim, that the biſhop of Rome is the ſupreme lord of the univerſe, and that neither princes nor biſhops, civil governors nor eccleſiaſtical rulers, have any lawful power in church or ſtate, that is not derived from them. In conſequence of this arrogant pretenſion, they not only claimed the right of diſpoſing of eccleſiaſtical benefices, but of conferring civil dominion, and of dethroning kings and emperors, according to their good pleaſure. They alſo aſſumed to themſelves the power of diſpoſing of the various offices of the church, and of creating and depoſing biſhops, abbots, and canons, according to their fancy. Inſtances of theſe practices occur in the pontificates of Innocent III. Honorius III. Gregory IX. and of ſeveral of their ſucceſſors. And Boniface VIII. maintained in the moſt expreſs and impudent terms, that the univerſal church was under the dominion of the pontifs, and that princes and lay patrons, councils and chapters, had no more power in ſpiritual things than what they derived from Chriſt's vicar upon earth. Under Innocent III. and Nicolas IV. the poſſeſſions and revenues of the Roman ſee received very conſiderable augmentation, partly by the events of war, and partly by the munificence of kings and emperors; and arrived at that high degree of grandeur and opulence, which it yet maintains even in our times. The former of theſe pontifs followed the ſteps of Gregory VII. and not only uſurped the deſpotic government of the church, but claimed alſo the empire of the world, and thought of nothing leſs than ſubjecting the kings and princes of the earth to his lordly ſceptre. In Aſia and Europe he diſpoſed of crowns and ſceptres with the moſt wanton ambition. The Roman pontifs derived great advantages in the exerciſe of their dominion from the attachment and zeal of the ſeveral orders of MENDICANTS. In the fourteenth century the papal authority diminiſhed by reaſon of the continued reſidence of the *popes* in France; and in the fifteenth century, by the ſchiſm which happened in the papacy, the dawnings of the reformation, and a variety of other concurring cauſes. In the councils of Conſtance, held in 1414, and of Baſil, opened in 1431, the power of the Roman pontifs was declared to be inferior and ſubordinate to that of general councils, and the papal impoſitions, called expectatives, reſervations, and proviſions, were entirely annulled. The reviſal of learning, and the progreſs of the reformation in the ſucceeding century, contributed very much to the abridgment of the papal authority; not only by withdrawing ſeveral provinces from the yoke of papal tyranny, but by producing a change in the ſentiments of many kings and princes, and ſovereign ſtates, who adhered to the religion of Rome, with reſpect to the claims and

pretensions of its bishop. Besides, it is necessary to observe, that the authority of the *pope* is circumscribed by various limits in the different countries where his spiritual jurisdiction is acknowledged; and that in all his decisions relating to the government of the church, he previously consults the cardinals, who form his privy-council; and in matters relating to religious doctrine, he is obliged to ask the advice of eminent divines; and that matters of different degrees of moment are referred to the conduct of certain colleges, called CONGREGATIONS. It is well known, that when the authority of the *pope* declined in Europe, he fought to extend the limits of his spiritual dominion to other parts of the globe, and for this purpose deputed missionaries to gain profelytes. And a new order was formed, that became afterwards so famous, under the appellation of JESUITS, in order to preserve those parts of the papal dominions that remained yet entire, and to augment them by new acceſſions. The fate of this fraternity is well known; and many circumſtances ſeem to concur in different countries, hitherto devoted to the ſee of Rome, that are likely to reduce within very narrow limits the ſpiritual juriſdiction and dominion of the *pope*.

The *pope* is choſen by the cardinals out of their own body.

In the firſt ages of the church, the people and the prieſts, and ſometimes only the prieſts, elected the *pope*, according to the plurality of voices. The emperors afterwards claimed the right of confirming the election. In the eighth century, *pope* Adrian I. in a council of biſhops aſſembled at Rome, conferred upon Charlemagne and his ſucceſſors the right of election; and they referred to themſelves the privilege of approving the perſon that was elected by the prieſts and people; nor was the conſecration of the elected pontif valid, unleſs performed in the preſence of the emperor's ambaſſadors. The election, however, after undergoing many revolutions as to the form of it, is now referred to the CARDINALS in CONCLAVE.

The ſee of the *pope* is at Rome, whence he iſſues out his orders, called *briefs* and *bulls*, throughout the catholic world.

Hiſtory mentions a *popeſs*, Joan. The reality hereof has been oppoſed and defended by many learned men. The tradition might poſſibly take its riſe from the weakneſs of *pope* John VIII. in reſtoring Photius to his communion, and owning him as true patriarch; for he hence got the appellation of woman; as that prince called *king Mary* did, by leaving himſelf to be governed by queen Mary his wife.

M. Spanheim, profeſſor of theology at Leyden, has lately written very amply on the ſubject; and ſhews it to be a queſtion *de facto*, ſcarce determinable at this time of day.

POPE, in *Ornithology*, a name by which the people in many parts of England call the *anas oſtrica clypeis*. See PUFFIN.

POPEDOM, or PAPARY, in *Eccleſiaſtical Hiſtory*, denotes the office and juriſdiction of the POPE.

POPERY, in *Eccleſiaſtical Hiſtory*, comprehends the religious doctrines and practices adopted and maintained by the church of Rome. The following ſummary, extracted chiefly from the decrees of the council of Trent, continued under Paul III. Julius III. and Pius IV. from the year 1545 to 1563, by ſucceſſive ſeſſions, and the creed of pope Pius IV. ſubjoined to it, and bearing date November 1564, may not be unacceptable to the reader. One of the fundamental tenets, ſtrenuouſly maintained by popiſh writers, is the infallibility of the church of Rome; though they are not agreed, whether this privilege belongs to the pope, or a general council, or to both united; but they pretend that an infallible living judge is abſolutely neceſſary to determine controverſies, and to ſecure peace in the Chriſtian church. However proteſtants alledge, that the claim of infallibility in any church is not juſtified by the authority of Scripture; much leſs does it pertain to the church of Rome; and that it is inconſiſtent with the nature of religion, and the perſonal obligations of its profeſſors; and that it has proved ineffectual to the end for which it is ſuppoſed to be granted, ſince popes and councils have diſagreed in matters of importance, and they have been incapable, with the advantage of this pretended infallibility, of maintaining union and peace. See INFALLIBLE.

Another eſſential article of the popiſh creed is the ſupremacy of the pope, or his ſovereign power over the univerſal church. On this ſubject it is maintained, that every Chriſtian, under pain of damnation, is bound to be ſubject to the pope; that no appeals may be made from him; and that he alone is the ſupreme judge of all perſons, in all eccleſiaſtical cauſes, but that he himſelf can be judged by no man. To this purpoſe they aſſert, that the church of Rome is the catholic church; the mother and miſtreſs of all churches; that the pope is the vicar of Chriſt, ſucceſſor of St. Peter, and the ſupreme paſtor over all the world. And they likewiſe aſſert his dominion over temporal princes; pretending that he may over-rule what they command; excommunicate and depoſe them, if they contradict his commands; and abſolve their ſubjects from allegiance, and exempt the clergy from their juriſdiction.

This exorbitant power hath been challenged by the pope for many ſucceſſive ages, and in ſeveral inſtances actually exerciſed. Thus Gregory VII. excommunicated the emperor Henry IV. and gave away his kingdoms to Rudolphus, duke of Sweden. Gregory IX. excommunicated the emperor Frederick II. and abſolved his ſubjects from their oath of allegiance. Pope Paul III. excommunicated and depoſed Henry VIII. king of England, and commanded all his ſubjects, under a curſe, to withdraw their obedience from him. Pope Pius V. and Gregory XIII. damned and depoſed queen Elizabeth, and abſolved her ſubjects from their allegiance. And this practice has been warranted by the decrees of the third Lateran council under pope Alexander III. and by the fourth Lateran council under pope Innocent III. though it is contrary to the expreſs language of Scripture, to the doctrine and conduct of the apoſtles and primitive fathers, and to the confeſſions and practice of the ancient biſhops of Rome, and altogether inconſiſtent with the rights of government and the welfare of ſociety.

Farther, the doctrine of the ſeven ſacraments is a peculiar and diſtinguiſhing doctrine of the church of Rome: theſe are baptiſm, confirmation, the euchariſt, penance, extreme unction, orders, and matrimony. The council of Trent (ſeſſ. 7. can. 1.) pronounces an anathema on thoſe who ſay, that the ſacraments are more or fewer than ſeven, or that any one of the above number is not truly and properly a ſacrament. And yet it does not appear that they amounted to this number before the twelfth century, when Hugo de St. Victore, and Peter Lombard, about the year 1144, taught, that there were ſeven ſacraments. The council of Florence, held in 1438, was the firſt council that determined this number. Theſe ſacraments confer grace, according to the decree of the council of Trent (ſeſſ. 7. can. 8.) *ex opere operato*, or by the mere adminiſtration of them: three of them, *viz.* baptiſm, confirmation, and orders, are ſaid (can. 9.) to impreſs an indelible character, ſo that they cannot be repeated without ſacrilege; and the efficacy of every ſacrament depends on the intention of the prieſt by whom it is adminiſtered (can. 11.) Pope Pius expreſly enjoins, that all theſe ſacraments ſhould be adminiſtered according to the received and approved rites of the catholic church. With regard to the euchariſt in particular, we may here obſerve, that the church of Rome holds the doctrine of TRANSUBSTANTIATION; the neceſſity of paying divine worſhip to the conſecrated bread, or HOST; the propitiatory ſacrifice of the MASS, according to their ideas of which Chriſt is truly and properly put to death in a ſacrifice, as often as the prieſt ſays maſs; and *ſolitary* MASS, in which the prieſt alone, who conſecrates, communicates; and allows COMMUNION only in one kind, viz. the bread, to the laity. Seſſ. 14.

The doctrine of MERITS is another diſtinguiſhing tenet of *popery*; with regard to which the council of Trent has expreſly decreed (ſeſſ. 6. can. 32.) that the good works of juſtified perſons are truly meritorious; deſerving not only an increaſe of grace, but eternal life, and an increaſe of glory; and it has anathematized all who deny this doctrine. Of the ſame kind is the doctrine of ſatisfactions; which ſuppoſes that penitents may truly ſatisfy, by the afflictions they endure under the diſpenſations of Providence, or by voluntary penances to which they ſubmit, for the temporal penalties of ſin, to which they are ſubject, even after the remiſſion of their eternal puniſhment. Seſſ. 6. can. 30. & ſeſſ. 14. can. 8. & 9. In this connection we may mention the popiſh diſtinction of venial and mortal ſins: the greateſt evils ariſing from the former are the temporary pains of purgatory; but no man, it is ſaid, can obtain the pardon of the latter without confeſſion to a prieſt, and performing the penances which he impoſes.

The council of Trent (ſeſſ. 14. can. 1.) has expreſly decreed, that every one is accurſed, who ſhall affirm, that PENANCE is not truly and properly a ſacrament inſtituted by Chriſt in the univerſal church, for reconciling thoſe Chriſtians to the divine majeſty, who have fallen into ſin after baptiſm; and this ſacrament, it is declared, conſiſts of two parts, the matter and the form; the matter is the act of the penitent, including contrition, confeſſion, and ſatisfaction; the form of it is the act of abſo-

fession on the part of the priest. Accordingly it is enjoined, that it is the duty of every man, who hath fallen after baptism, to confess his sins once a year, at least, to a priest; that this confession is to be secret, for public confession is neither commanded nor expedient; and that it must be exact and particular, including every kind and act of sin, with all the circumstances attending it. When the penitent has so done, the priest pronounces an absolution, which is not conditional or declarative only, but absolute and judicial. This secret, or auricular CONFESSION, was first decreed and established in the fourth council of Lateran, under Innocent III. in 1215 (cap. 21). And the decree of this council was afterwards confirmed and enlarged in the council of Florence, and in that of Trent, which ordains, that confession was instituted by Christ; that by the law of God it is necessary to salvation; and that it has been always practised in the Christian church. As for the penances imposed on the penitent, by way of satisfaction, they have been commonly the repetition of certain forms of devotion, as PATER-NOSTERS, or AVE-MARIAS, the payment of stipulated sums, pilgrimages, fasts, or various species of corporal discipline. But the most formidable penance in the estimation of many, who have belonged to the Romish communion, has been the temporary pains of PURGATORY. But under all the penalties which are inflicted or threatened in the Romish church, it has provided relief by its INDULGENCES, and prayers or masses for the dead; performed professedly for relieving and rescuing the souls that are detained in purgatory. Sess. 25.

Another article that has been long authoritatively enjoined and observed in the church of Rome, is the celibacy of her clergy. This was first enjoined at Rome by Gregory VII. about the year 1074, and established in England by Anselm, archbishop of Canterbury, about the year 1105; though his predecessor Lanfranc had imposed it upon the prebendaries and clergy that lived in towns. And though the council of Trent was repeatedly petitioned by several princes and states to abolish this restraint, the obligation of celibacy was rather established than relaxed by this council; for they decreed, that marriage contracted after a vow of continence is neither lawful nor valid; and thus deprived the church of the possibility of ever restoring marriage to the clergy. For if marriage, after a vow, be in itself unlawful, the greatest authority upon earth cannot dispense with it, nor permit marriage to the clergy, who have already vowed continence. Sess. 24. can. 9. See CELIBATE.

To the doctrines and practices above recited may be farther added the worship of IMAGES; to justify which, the papists often leave the second commandment out of their catechisms (see DECALOGUE); the invocation of saints and angels, with respect to which the council of Trent decreed, that all bishops and pastors, who have the cure of souls, do diligently instruct their flocks, that it is good and profitable humbly to pray unto the saints, and to have recourse to their prayers, help, and aid; for which practice no scripture command or example, nor any testimony within the first three hundred years after Christ, can be pleaded: the worship of sacred RELICS, by which they understand not only the bodies and parts of the bodies of the saints, but any of those things that appertained to them, and which they touched; and the celebration of divine service in an unknown tongue, to which purpose the council of Trent hath denounced an anathema on any one who shall say, that mass ought to be celebrated only in the vulgar tongue. Sess. 25, and sess. 22. can. 9. Though the council of Lateran under Innocent III. in 1215 (can. 9.) had expressly decreed, that, because in many parts, within the same city and diocese, there are many people of different manners and rites mixed together, but of one faith, the bishops of such cities or dioceses should provide fit men for celebrating divine offices, according to the diversity of tongues and rites, and for administering the sacraments.

We shall only add, that the church of Rome maintains, that unwritten traditions ought to be added to the holy Scriptures, in order to supply their defect, and regarded as of equal authority; that the books of the APOCRYPHA are canonical scripture; that the vulgate edition of the Bible is to be deemed as authentic; and that the Scriptures are to be received and interpreted according to that sense which the holy mother church, to whom it belongs to judge of the true sense, hath held, and doth hold, and according to the unanimous consent of the fathers. Sess. 4. See INDEX.

Such are the principal and distinguishing doctrines of *popery*, most of which have received the sanction of the council of Trent; and that of the creed of pope PIUS IV. which is received, professed, and sworn to by every one, who enters into holy orders in the church of Rome; and at the close of this creed, we are told, that the faith contained in it is to absolutely and indispensably necessary, that no man can be saved without it. Harduin's Concil. tom. x. p. 1—211.

Many of the doctrines of *popery* were relaxed, and very favourably interpreted by M. de Meaux, bishop of Condom, in his Exposition of the Doctrine of the Catholic Church, first printed in the year 1671; but this edition, which was charged with perverting, in endeavouring to palliate the doctrine of the church, was censured by the doctors of the Sorbonne, and actually suppressed: nor does it appear that they ever testified their approbation in the usual form, of subsequent and altered editions. See the examination of this work by archbishop Wake, in the Preservative against *Popery*, vol. iii. p. 3—112.

POPERY, *declaration against*. See DECLARATION.

POPERY, *laws against*. See PAPISTS, MASS-*books*, PARENTS, and PRÆMUNIRE.

POPLAR, *populus*, in *Botany*, a genus of the *dioecia octandria* class. Its characters are these: the male and female flowers grow upon separate trees; the male flowers, or catkins, have one oblong, loose, cylindrical empalement, which is imbricated; under each scale, which is oblong, plain, and cut on the border, is situated a single flower, without any petal, having a nectarium of one leaf, turbinated at the bottom, and tubulous at the top; and eight stamina, terminated by large four-cornered summits; the female flowers are in catkins like the male, but have no stamina; they have an oval acute pointed germen, with scarce any style, crowned by a four-pointed stigma; the germen afterward becomes an oval capsule, with two cells, including many oval seeds, having hairy down. Linnæus reckons five, and Miller seven species.

The *poplar*, whether black or white, may be easily propagated, either by layers, cuttings, or suckers, of which the white kind always produces a great many from the root. The best season for the transplanting these suckers is in October, when the leaves begin to decay; and they should be removed into a nursery for two or three years, at the end of which time they will have got strength enough to be transplanted into the places where they are to remain.

When they are to be propagated by cuttings, it is best to do that in February, cutting off truncheons two or three feet long; which being thrust down a foot and a half deep in the ground, will take root very quickly, and if the soil be moist, will grow to a considerable size in a very few years.

The black *poplar* is not so easily raised from these large truncheons, but should be planted in cuttings, of about a foot and a half long, planting them a foot deep in the ground. This will grow on almost any soil; but does much better on a moist one than on any other. They are the fittest of all trees for raising a shade quickly, as they will grow fourteen feet in height sometimes in one season, and in four or five years will be large trees. Miller. See ARBRE-*tree*, and TACAMAHACCA.

POPLAR-*galls*. The black *poplar* is famous among naturalists for producing a sort of *galls*, or protuberances, of various shapes and sizes, on its leaves and branches, which have been usually mistaken for the lodgments of worms hatched from the eggs of an ichneumous fly; but they are in reality produced by the operation of a viviparous insect, called the PUCERON, for the bringing up of its offspring.

These *galls* are of the bladder-kind, being usually thinned over, and more or less hollow within, not woody, as those of the oak, &c. They proceed from different parts of the plant, some from the pedicles of the leaves, and many from the young shoots; they are very various in figure, some being roundish, others oblong, others crooked and contorted in various directions, and some of them are in the figure of horns, like those of the turpentine-tree, and of the same origin.

POPLES, in *Anatomy*, the inner part of the juncture where by the thigh-bone is articulated with the tibia; popularly called the *ham*.

POPLICANI, POPLICANI, or PUBLICANI, a name given in the West to the Manichees; or rather to a particular branch thereof, called in the East PAULICIANS.

POPLIFUGIA, in *Antiquity*. See FUGALIA.

POPLITÆUS, or SUB-POPLITÆUS, a muscle which arises from the external and inferior protuberance of the thigh-bone, and passing over the joint obliquely, is inserted into the superior and internal part of the tibia. It is fixed above, by a strong narrow tendon, to the outer edge of the inner condyle of the os femoris, and to the neighbouring posterior ligament of the joint; from thence it runs obliquely downward, under the inner condyle of the os femoris; its flat and pretty thick fleshy body increasing gradually in breadth, till it is fixed in the backside of the head of the tibia all the way to the oblique line observable

ferrable on that ſide. It aſſiſts in bending of the leg, and turns it inwards. See *Tab. Anat. [Myol.] fig. 7. n. 27. 27. 27.* See LEG.

POPLITEA, in *Anatomy*, is a name given to the third vein of the leg.

It ariſes from the heel, where it is formed out of ſeveral branches coming both from the heel and ankle.

It lies pretty deep in the fleſh; and, aſcending up to the ham, terminates in the crural vein.

POPPY, *papaver*, in *Botany*, a genus of the *polyandria monogynia* claſs. Its characters are theſe: the empalement of the flower is oval, indented, and compoſed of two almoſt oval, concave, obtuſe leaves, which fall off; the flower has four large roundiſh petals, which ſpread open, with a great number of hair-like ſtamina, terminated by oblong, compreſſed, erect ſummits; in the centre is placed a large, roundiſh germen, having no ſtyle, but crowned by a plain, radiated, target-ſhaped ſtigma; the germen afterward becomes a large capſule, crowned by the plain ſtigma, having one cell, opening in many places at the top under the crown, and is filled with ſmall ſeeds. There are nine ſpecies, including a great number of varieties.

We have many ſpecies of this plant cultivated in gardens for the beauty of the flowers. They are all eaſily propagated by ſowing the ſeeds in September. When the young plants come up, they are to be cleared from weeds, and thinned to a proper diſtance by pulling ſome up where they ſtand too thick; for they never thrive well if they are tranſplanted. They are to be left, according to their ſizes, at the diſtance of a foot and a half for the larger, and about half this ſpace for the leſs.

They are very ſhowy flowers, and make a ſplendid appearance in gardens; but they are of ſhort duration, and of an offenſive ſmell, which makes them leſs valued at preſent than they have been.

Some ſow theſe plants in ſpring, but it is not ſo well; becauſe they then have not time to get ſtrength before autumn, when they are to flower; and for that reaſon thoſe ſown in ſpring uſually flower weakly. Miller.

Thoſe moſt uſed for medicinal purpoſes, are the white, *papaver hortenſe ſemine albo*; and black, *papaver hortenſe ſemine nigro*. The heads of theſe plants are of ſingular virtue to promote ſleep, aſſuage pain, &c. They ſtop diarrhœas, hæmorrhages, &c.

Of the juice of the white *poppy*, which is the largeſt, is prepared the OPIUM ſold in the ſhops; (for the method of cultivating which at Babar, ſee London Med. Obſ. vol. v. p. 317, &c.) and of the juice of the leaves, MECONIUM.

A decoction of *poppy* heads in water, ſtrongly preſſed out, depurated by ſettling, then clarified with white of eggs, and inſpiſſated, yields an extract amounting to one-fifth or one-ſixth the weight of the heads. It is ſaid that two grains of this preparation are equivalent to one grain of opium, and that the extract is not liable to produce a naufea or giddineſs which generally follow the uſe of pure opium. See Mr. Arnot's method of preparing it, &c. in the Edinb. Medical Eſſays, vol. v. art. 11.

The common wild red *poppy*, or *papaver erraticum*, is one of the moſt troubleſome and miſchievous weeds the farmers are plagued with among their corn, and it is the moſt difficult to thoroughly deſtroy of almoſt any other. Its ſeed will lie a long time in land unplough'd, without ever ſhooting; but they will be ſure to grow with the firſt crop of corn. Mr. Tull gives an inſtance of the ſeeds of this plant being buried four and twenty years in a field of ſaint-foin, and at the end of that time, the land being ploughed for wheat, they all grew up among the corn, though they had lain dormant ſo long before.

The only part made uſe of is the flowers, which yield on expreſſion a deep red juice, imparting the ſame colour to watery liquors, and a brighter though paler red to rectified ſpirit; and the colouring matter, on the admixture of alkaline liquors, is obſerved to change into a dark purple, and not into a green, like that of clove-gilly-flowers, red roſes, and other bright red flowers. A ſtrong infuſion of them is prepared in the ſhops, by pouring four pints and a half of boiling water upon four pounds of the freſh leaves, ſtirring them over the fire till the flowers are all immerged, and ſetting them by to ſteep for a night. This infuſion, preſſed out and depurated by ſettling, is reduced, by a proper addition of ſugar, into a deep red ſyrup. It has been the general opinion of authors, that the narcotic quality of the *red poppy* lay in its flowers; but Mr. Boulduc, in his courſe of experiments for the finding out an European plant which ſhould yield us a juice of the nature of the opium of the Eaſt, without its bad effects, found that the virtue of this plant, which is very great, lay much more in the heads than the flowers; and from four ounces of theſe heads, while freſh and green, he obtained five drachms of a ſolid extract, of the nature of opium, two, three, or four grains of which were a full doſe, and which poſſeſſed the virtues of opium, and might be given with great ſucceſs and ſafety in obſtinate coughs and other ſuch caſes. Hiſt. Acad. Par. 1712.

POPPY, *horned*. See CELANDINE.

The yellow horned *poppy*, called by authors *papaver corniculatum luteum*, is one of thoſe vegetable poiſons of our own growth, which may be very miſchievous by their not being generally known or ſuſpected to be ſo. We have an account of the ſtrange effects of this plant in the Philoſophical Tranſactions, in an inſtance of a family in Cornwall, who eat of a pye made of the roots of this inſtead of thoſe of eryngo, or ſea-holly, which it is the cuſtom of the poorer people there to make into a coarſe ſort of a pye for their food. See Phil. Tranſ. N° 242.

POPPY, *prickly, argemone*, in *Botany*, a genus of the *polyandria monogynia* claſs. Its characters are theſe: the flower hath a three-leaved empalement, and ſix roundiſh petals, which ſpread open, and are larger than the empalement; and in the centre is ſituated an oval five-cornered germen, which is attended by a great number of ſtamina; it becomes an oval ſeed-veſſel, having five angles and cells, filled with ſmall rough ſeeds. Miller mentions only one ſpecies, which is an annual plant, very common in moſt parts of the Weſt Indies, called by the Spaniards *ſpec. ad inferos*, or the devil's fig. There is no great beauty or uſe in this plant among us. Linnæus enumerates three ſpecies.

POPPY, *ſpotted*, a ſpecies of the *cucubalus*, or *berry-bearing* CHICK-WEED. This ſtands in the catalogue of medicinal plants under the title *lichen album*. See LICH.

POPPY-*ſeeds*. The *poppy-ſeed* is of a more delicious taſte than ſweet almonds; it is oily and farinaceous. Dr. Alſton ſays, he has eaten large quantities of the black as well as the white ſeed, and never found it inſalubrious or noxious. See Med. Eſſ. Edinb. vol. v. art. 12.

If emulſions of *poppy-ſeeds* have been found ſerviceable in coughs, catarrhs, heat of urine, and other like diſorders, their virtue is to be aſcribed not to an anodyne, but an emollient quality.

Theſe ſeeds are uſed in food in ſome places, as is their expreſſed oil, which is as wholeſome as olive-oil. Vide Matthiol. p. 476. Geoffr. Mat. Med. vol. ii. p. 313.

The qualities and uſes of this *oil*, with regard to painting, are much the ſame as thoſe of NUT-*oil*; only when it is perfectly good, it is more clear and limpid, and will dry better than the beſt oil of that kind.

POPPY, *ſyrup of*. See MECONIUM.

POPPY, *water*. See WATER.

POPULAGO, in *Botany*. See *Marſh* MARYGOLD.

POPULAR, *popularis*, ſomething that relates to the common people.

The Roman nobility was diſtinguiſhed into two factions; the *optimates*, who adhered ſtrenuouſly to the miniſtry, the ſenate, &c. in oppoſition to the people; and the *populares*, who favoured the rights and pretenſions of the people, in oppoſition to the nobleſſe.

POPULAR *action*. See ACTION.

POPULAR *diſeaſes* are ſuch as become common, and run through the body of the people; called alſo *endemii* and *epidemical* DISEASES.

Hippocrates has written expreſly, De Morbis *Popularibus*.

POPULAR *errors*, are ſuch as people imbibe from one another, by cuſtom, education, and tradition, without having conſidered the reaſon or foundations thereof.

POPULARIA, among the Romans, were ſtreets or places where the people ſat and beheld the games and horſe races.

POPULATION, the ſtate of a country with reſpect to the number of people. See on this ſubject EXPECTATION *of life*, MARRIAGE, MORTALITY, and POLITICAL *arithmetic*.

POPULEUM, or POPULNEUM, in *Pharmacy*, an ungnent prepared of the buds of black poplar, violet leaves, navelwort, and lard bruiſed and macerated; to which are added bramble-tops, leaves of black poppies, mandragors, henbane, nightſhade, lettuce, and burdock, boiled in roſe-water, and ſtrained. It was formerly much uſed as a cooler, in burns, ſcalds, and all ſorts of inflammations, and alſo to aſſuage arthritic pains; but it is now almoſt entirely diſregarded.

POPULICANI. See POPLICANI.

POPULNEUM. See POPULEUM.

POPULUS, in *Botany*. See POPLAR.

PORBEAGLE, in *Ichthyology*, a ſmall ſpecies of SHARK, found on the coaſt of Cornwall; the noſe is long, ſlender towards the end, and ſharp-pointed; the mouth placed far beneath; the body thick and deep, but extremely ſlender juſt at the letting on of the tail; the firſt back-fin is placed almoſt in the middle, the other pretty near the tail; the belly is very deep; the ventral and anal fins are very ſmall; the tail is bifurcated, the upper fork being a little longer than the other. Pennant.

PORCELAIN,

PORCELAIN, or PURCELAIN, a fine ſort of earthen-ware, chiefly manufactured in China, and thence alſo called *china*, or *china-ware*; but brought into Europe from other parts of the Eaſt, eſpecially Japan, Siam, Surat, and Perſia.

The Chineſe call it *tſe-ki*. The word *porcelain* is but little known there; except among a few workmen and merchants; and ſeems derived from the Portugueſe, *porcelana, a cup*.

Scaliger and Cardan, though generally of contrary ſentiments, are yet agreed, that what the Romans called *vaſa murrhina, murrina* and *murrea*, which were firſt ſeen at Rome in Pompey's triumph, and afterwards became ſo very precious, were the *porcelain* of our times.

This may be true: but if the opinion be only founded on Pliny's deſcription of thoſe veſſels, one would rather take them to have been made of a kind of precious ſtones, of a whitiſh colour, but variouſly veined and variegated, found in ſome parts of Parthia.

Oriens murrhina mittit, &c. Plin. Hiſt. Nat. lib. xxxvii. cap. 2. See MURRHINE.

Be this as it will, it is certain, that both Cardan and Scaliger are miſtaken when they tell us, that *porcelain* is made of eggs and ſea-ſhells, beaten ſmall, and buried under-ground for eighty or one hundred years. The account we ſhall here give will put that matter out of all queſtion.

It is not known who was the inventor of *porcelain*; the Chineſe annals, which commonly contain every thing in any reſpect memorable, are perfectly ſilent about it; nor do we know much more of the time of its invention: only it is certain it muſt have been before the beginning of the fifth century, the annals of Feou-leam relating that from the ſecond year of the reign of the emperor Tam, about the year of Chriſt 442, the workers in *porcelain* of that province had alone furniſhed the emperors with it.

Porcelain is now made chiefly, ſome ſay wholly, at Kingtetching, a large town in the province of Kyangſi.

There is ſome indeed made in the provinces of Kanton and Fokyen; but it is of little account, being far inferior in beauty and value to the *porcelain* of Kingtetching. That of Fokyen is perfectly white, without either gloſs or painting. Attempts have been made to remove the manufacture from Kingtetching to Pekin, and other places, but in vain; the *porcelain* made in the new manufactories never coming up to that of the old: ſo that Kingtetching has the honour of ſupplying the greateſt part of the world with this commodity. F. du Halde aſſures us, that even the Japaneſe come to China for it.

There is a current opinion among the Chineſe themſelves, that the *porcelain*-ware of former times was greatly ſuperior to that which they make at preſent; and that the burying china in the earth for a long time, adds to its beauty; but all this is founded on error. The truth is, that our merchants beat down the price of the ware, and thereby compel them to make a worſe kind in general; but they are able to do as fine things now as ever. What gave birth to the opinion, that burying *porcelain*-ware made it good, was, that finer pieces than ordinary are ſometimes found buried. Theſe are all precious vaſes, which the poſſeſſors buried by way of ſecurity in the times of civil war; and it is no wonder, that there are none but of the fineſt kind found buried on theſe occaſions.

PORCELAIN, *manufacture of*. *Porcelain* makes a very curious article in commerce, and not leſs ſo in natural hiſtory. Its manufacture for a long time paſſed as a myſtery in Europe; and that in ſpite of all the endeavours of the Jeſuit miſſionaries to penetrate into the ſecret. The veil, however, was at length drawn: and in a letter of F. d'Entrecolles to F. Orry, from Jauchew, dated September 1, 1712, and publiſhed in French, the whole proceſs is deſcribed in all its circumſtances; with an extract whereof we ſhall here gratify the curious reader. In the manufacture of *porcelain* there are four principal things to be conſidered, viz. the matter it is made of; the art of forming the veſſels, and other works; the colours wherewith it is painted; and, laſtly, the baking or giving it the proper degree of fire. Each of which will make the ſubject of a ſeparate article.

PORCELAIN, *materials of*. There are two kinds of earths, and as many kinds of oils, or varniſhes, uſed in the compoſition of *porcelain*. The firſt earth, called KAOLIN, is intermixed with glittering corpuſcles; the ſecond, called PETUNSE, or PETUNTSE, is a plain white, but exceedingly fine, and ſoft to the touch. They are both found in quarries twenty or thirty leagues from Kingtetching; and hither theſe earths, or rather ſtones, are brought in a number of little barks, inceſſantly paſſing up and down the river Jaotcheou, for that purpoſe. The petunſes are brought in form of bricks; having been ſo cut out of the quarries, where they are naturally pieces of a very hard rock. The white of the beſt petunſe is to border a little on green.

The firſt preparation of theſe bricks is, to break and pound them, firſt into a coarſe powder with iron mallets, then in mortars with peſtles that have ſtone heads, armed with iron, and wrought either with the hand, or with mills.

When the powder is rendered almoſt impalpable, they throw it in a large urn full of water, ſtirring it briſkly about with an iron inſtrument. After the water has reſted a little while, they ſkim off from the top a white ſubſtance formed there, of the thickneſs of four or five fingers, and diſpoſe this ſcum or cream in another veſſel of water. They then ſtir again the water of the firſt urn, and again ſkim it, and thus alternately, till there remain nothing but the gravel of the petunſes at bottom; which they lay aſreſh under the mill, for a new powder.

As to the ſecond urn, wherein are put the ſkimmings of the firſt, when the water is well ſettled, and become quite clear, they pour it off; and with the ſediment, collected at bottom in form of a paſte, fill a kind of moulds: whence, when almoſt dry, they take it out, and cut it into ſquare pieces, which are what they properly call ſquare *petunſes*; reſerving them to be mixed with the kaolin in the proportion hereafter aſſigned.

Theſe ſquares are ſold by the hundred, but it is very rare to meet with them unfalſified; the workmen, who, like the reſt of the Chineſe are arrant knaves in their dealings, uſually mixing refuſe along with them; ſo that they are commonly obliged to purify them before they can be employed.

The *kaolin*, which is the other earth uſed in *porcelain*, is much ſofter than the petunſe, when dug out of the quarry; yet is it this, which by its mixture with the other, gives the ſtrength and firmneſs to the work. F. d'Entrecolles obſerves, that ſome Engliſh or Dutch, having procured ſome petunſes to be bought privately; upon their attempting to make *porcelain* at their return into their own country, could not ſucceed for want of taking kaolin along with it: which the Chineſe being apprized of, ſaid, humorouſly, "That the Europeans were won-"derful people, to go about to make a body, whoſe fleſh "was to ſuſtain itſelf without bones."

The mountains whence the kaolin is dug, are covered without-ſide with a reddiſh earth. The mines are deep, and the matter is found in glebes or clods. The author is of opinion, that the white earth of Malta is not much different from the kaolin, except that it wants the ſilvered particles. The preparation of kaolin is the ſame with that of the petunſes, except that the matter being leſs hard, leſs labour is required. The oil or varniſh, which makes the third ingredient in *porcelain*, is a whitiſh liquid ſubſtance: this is drawn from the hard ſtone, whereof the petunſes are formed; that which is the whiteſt, and whoſe ſtains are the greeneſt, being always choſen for this purpoſe.

The manner of preparing the oil is thus: the petunſes, being waſhed, undergo the ſame preparations as for making the ſquares; excepting that the matter of the ſecond urn is not put in moulds, but the fineſt part of it taken to compoſe the oil. To a hundred pounds of this matter they caſt a mineral ſtone, called *ſhekau*, or *kekao*, reſembling our alum: this ſtone is firſt heated red hot, and thus reduced in a mortar into an impalpable powder; and ſerves to give the oil a conſiſtence; which, however, is ſtill to be kept liquid.

The oil of lime makes the fourth ingredient; the preparation whereof is much more tedious and circumſtantial. They firſt diſſolve large pieces of quick lime, and reduce it to a powder, by ſprinkling water on it; on this powder they lay a couch of dry fern, and on the fern another of the ſlacked lime, and thus alternately, till they have got a moderate pile; which done, they ſet fire to the fern: the whole being conſumed, they divide the aſhes that remain on new couches of dry fern; ſetting them on fire as before. And this they repeat five or ſix times ſucceſſively, or even more; the oil being ſtill the better, as the aſhes are oftener burnt.

In the annals of Feou-leam it is ſaid, that inſtead of fern they anciently uſed the wood of a kind of medlar-tree; and that it was this gave the ancient *porcelains* that admirable hue, which the moderns cannot come up to for want of that wood. But this is become ſcarce in the country, and is no longer uſed. It is certain, however, the quality of the fern and lime contribute very much to the goodneſs of the oil.

A quantity of theſe aſhes of fern and lime is now thrown into an urn full of water: and to a hundred pounds of aſhes is added a pound of ſhekau, which diſſolves therein. The reſt being performed after the ſame manner as in preparing the earth of the petunſes, the ſediment found

at the bottom of the second urn, and which is to be kept liquid, is what they call the *oil of lime*; which the Chinese esteem as the soul of the former oil, and which gives the *porcelain* all its lustre.

This oil is easily sophisticated by adding water to increase the quantity; adding at the same time proportionably of the same stuff to maintain the consistence. Ten measures of oil of petunse usually go to one of lime. To have the mixture just, the two oils should be equally thick.

PORCELAIN *vessels, forming of.* The first thing is, to purify the petunse and kaolin; which, *for* the first, is done after the manner already described in preparing the squares. For the second, as its softness makes it dissolve easily, it is sufficient, without breaking it, to plunge it in an urn full of water in an open basket. The dregs that remain are perfectly useless, and are emptied out of the work-house when a quantity is got together.

The work-houses are properly vast yards walled round, with sheds and other conveniencies for the workmen to work under; as well as other buildings for them to live in. It is almost inconceivable what number of persons are employed in these works; there being scarce a piece of *porcelain* but passes through above twenty hands, before it comes to the painter's work-house; and above sixty before it be brought to perfection.

To make a just mixture of petunse and kaolin, regard must be had to the fineness of the *porcelain* to be made; for the finer *porcelains*, they use equal quantities; four parts of kaolin to six of petunse, for moderate ones; and never less than one of kaolin to three of petunse, for the coarsest.

The hardest part of the work is the kneading and tewing the two earths together; which is done in a kind of large basons, or pits, well paved, and cemented, wherein the workmen trample continually with their feet, relieving one another, till the mass be well mixed, grow hard, and become of the consistence required to be used by the potter.

The earth, when taken out of the basons, is kneaded a second time, but piece-meal, and with the hands, on large slates for the purpose; and on this preparation, in effect, it is, that the perfection of the work depends; the least heterogeneous body remaining in the matter, or the least vacuity that may be found in it, being enough to spoil the whole. The smallest grain of sand, nay, sometimes a single hair, shall make the *porcelain* crack, splinter, run, or warp.

The *porcelain* is fashioned or formed either with the wheel, like our earthen ware, or in moulds. See POTTERY. Smooth pieces, as cups, urns, dishes, &c. are made with the wheel. The reli, i. e. such as are in relievo, as figures of men, animals, &c. are formed in moulds, but finished with the chissel.

The large pieces are made at two operations: one half of the piece is raised on the wheel by three or four workmen, who hold it till it have acquired its figure; which done, they apply it to the other half, which has been formed in the same manner; uniting the two with *porcelain earth*, made liquid by adding water to it, and polishing the juncture with a kind of iron spatula.

After the same manner it is that they join the several pieces of *porcelain* formed in moulds, or by the hand; and after the same manner they add handles, &c. to the cups, and other works formed with the wheel.

The moulds are made after the manner of those of our sculptors; viz. of divers pieces, which severally give their respective figure to the several parts of the model to be represented; and which are afterwards united to form a mould for an entire figure. The earth they are made of is yellow and fat, dug out of its proper quarries, whereof there are abundance about Kingtetching. It is kneaded like potters earth, and when sufficiently mellow, fine, and moderately dry, beating it stoutly, they form it into moulds, according to the works required, either by hand, or on the wheel. These moulds are sold very dear, but they last a long time.

All the works made in moulds are finished by the hand, with several instruments proper to dig, smooth, polish, and to touch up the strokes that escape the mould; so that it is rather a work of sculpture than of pottery. There are some works wherein relievos are added, ready made, as dragons, flowers, &c. others that have impressions in creux; which last are engraven with a kind of puncheons. In the general, all *porcelain* works are to be sheltered from the cold, their natural humidity making them liable to break when they dry unequally.

To conceive the number of hands each piece of *porcelain* passes through before it is perfect, we shall close this article with what F. d'Entrecolles instances of a common tea-cup, before it be fit for the painter. The cup begins with the potter, who has the management of the wheel, where it acquires its form, height, and diameter. This operator has only three farthings sterling for a plate furnished with twenty-six cups: accordingly, they go out of his hands exceedingly imperfect, especially towards the foot, which are only informed lumps of earth, to be afterwards cut with a chissel, when the cup is dry. When it comes from the wheel, the cup is received by a second workman, who fits it to its base. A third takes it immediately from him, and applies it on a mould to bring it to its true form. This mould is on a kind of lathe. A fourth workman polishes the cup with a chissel, especially about the edges; and brings it to the thinness necessary to make it transparent: in doing which, he moistens it from time to time, left its dryness should make it break. When of its proper thickness, another workman turns it gently on a mould, to smooth its inside; taking a deal of care it be done equably, left any cavity be formed, or it warp. Other workmen add some ornaments in relievo; others, impressions in creux; others, only handles; as the quality of the cup requires. At last, they round and hollow the foot on the inside with the chissel; which is the function of a particular artist, who does nothing else.

This multiplicity of workmen is so far from retarding the work, that it is found, by experience, to go on the faster for it; as well as to be the better done; each workman, by a continual attention to the same thing, becoming very dextrous at it: besides saving the time of changing instruments, &c.

PORCELAIN, *painting of.* The Chinese painters, especially those that meddle with human figures, our author observes, are all bad workmen: he adds, that the defect is scarce any where so sensible as in the whapey, or *porcelain* painters, among whom, setting aside flowers and landschapes, which are sometimes tolerable, the greatest masters are not to be compared to ordinary apprentices among the Europeans, for the beauty and justness of design. But it is otherwise with the colours these whapey use; which are so exceedingly lively and brilliant, that there are but little hopes our workmen should ever come to vie with them.

The painting work is distributed among a great number of workmen, in the same laboratory: to one it belongs to form the coloured circle about the edges of the *porcelain*; another traces out flowers, which another paints: this is for waters and mountains alone; that for birds and other animals; and a third for human figures. There are *porcelains* made of all colours: both with regard to the grounds, and to the representations thereon. As to the colour of landschapes, &c. some are simple; such are all blues, which are those most usually seen in Europe; others are mixed up of several tints; and others, again, are heightened with gold.

The Chinese, for a great many ages, used only white *porcelain*. The first colour they employed was blue, and after that they came into the use of all the rest. Their ancient blues was prepared by themselves from a kind of lapis lazuli; but we now supply them with the smalt so much cheaper, that it is no longer worth their while to make it themselves. They used to prepare this only by giving a gentle calcination to the stone, and then beating it to powder, and grinding it to the utmost fineness in morrars of unglazed *porcelain*-ware, with pestles of the same.

The fine deep blue of the old *porcelain*-ware of China, is much valued by the curious; and it is much lamented, that the same colour is not used at this time. The art seems at present to be lost; but perhaps it might be recovered by trials.

It is certain that the Chinese have cobalt among them, and very probably they used a blue colour prepared from this, before they had any commerce with us: notwithstanding all the conjectures about their materials for colouring, this seems the most probable substance; and there is a way of preparing a colour from this, much superior to that now in use, which we call smalt.

Cobalt is a mineral containing arsenic and a blue vitrifiable earth. The common way of preparing smalt is, by roasting this cobalt in a reverberatory fire. This disposes it to vitrify, and drives off the arsenic it contains in fumes, which collected at the top, form true flowers of arsenic. It is very certain, however, from experiments, that if this arsenic could be preserved in the cobalt, the smalt would be of a much finer colour; for there are some kinds of cobalt which yield smalt without previous roasting; and as the arsenic is in a great measure contained in these, the smalts are much finer coloured.

Arsenic added to smalt, while in fusion, greatly exalts its colour also; and there is a way of procuring smalt from cobalt without fire, only by dissolving it in an acid, and precipitating that solution with oil of tartar. The smalt thus precipitated to the bottom, is of a much finer colour than any prepared by fire; but it is much more expensive, and prepared in less quantity. It is very pos-

sible

ſible that the Chineſe might have the art of making this kind of ſmalt before they knew us, and that to this was owing the fine blue of their *porcelain* ware: but when we trafficked with them, and they purchaſed ſmalt ſo much cheaper of us than they could make it themſelves, they naturally diſcontinued the manufacture of their own finer kind, without conſidering how greatly inferior the colour was which the other yielded. If this be the caſe, it will be eaſy to revive this art, and the adding the true old china blue to our European manufactures, in imitation of *porcelain*, may give them a value which they have not at preſent.

The red, which the Chineſe uſe, is made of our green vitriol, or common copperas, which they call *tſo-fan*. They put about a pound of this into a crucible; and lute on this another crucible inverted: this laſt has a hole cut in the top, which they keep covered or open at pleaſure. They ſet this crucible in a furnace of bricks, ſo contrived, as to throw all the flame upon the lower veſſel, in the way of our chemiſts reverberatory furnaces. They make a large fire of charcoal all round it, and obſerve the hole at the top; for ſo long as there aſcend thick black fumes through that, the matter is not ſufficiently calcined. They watch the going off of this fume, and when there appears in the place of it a fine and thin cloud, they take away the crucible, the matter being then ſufficiently burnt. They try this, however, by taking a little out, and examining the colour; if it is not ſufficiently red, they let it remain longer in the fire. When they find that it is of a good colour, they take away the fire, and leave the veſſels to cool; this done they find a cake of red matter at the bottom of the crucible, and a quantity of a finer powder about its ſides. They keep theſe ſeparate, the latter being the pureſt, the leaſt, and the brighteſt colour.

One pound of copperas affords about four ounces of this colour, and this is the red which they manage in different ſhades, and vary ſo much. See *Blown*-RED.

The Chineſe have alſo a white colour, which they uſe in their figures painted on the China: the ware itſelf is naturally white, and the varniſh, or oil of ſtone, is a great addition to its whiteneſs all over. But they have yet a way of making a much brighter and finer white than theſe, as may be ſeen in moſt of the fine China-ware where there is any white in the figures. This white is made in the following manner: they collect on the ſhores of their rivers a ſort of flint or agate, which is of a whitiſh hue, without veins, and tolerably tranſparent. It approaches very much to the nature of cryſtal, and probably cryſtal may be found to ſupply its place with us. They calcine this ſtone to a white powder, and to every ounce of this, when ground in their porcelain mortars to an impalpable fineneſs, they add two ounces of ceruſs in fine powder: this they mix with the varniſh, and lay on in the common way of other colours. This white mixture ſerves not only for the coloring white, but it is the baſis of ſeveral other of thoſe beautiful colours which we ſee on the China-ware, and which our manufacturers have been often perplexed what to make of. Their green colour is made of copper rulled with acid; and their fine deep violet colour is made of this green, by adding to it a due proportion of this white. It is not to be ſuppoſed that this effect is produced according to the common laws of mixing colours among our painters, for then the white and green would only make a paler green. But copper being a metal that as well gives a fine blue as a fine green, according to the nature of the ſubſtances it is mixed with, the white in this caſe alters the very nature of the green, and converts it into that fine and deep violet blue, which we may draw from copper by means of any of the volatile alkalis, ſuch as ſpirit of ſal ammoniac, ſpirit of hartſhorn, ſpirit of urine, or any the like liquor. The workmen know how to bring this blue to any degree, by putting in different proportions of the two colours. There is not any admixture of them, that will not produce a blue of ſome kind; but always the more of the green colour is uſed, the deeper the blue will be, and the leſs the paler. The yellow is made by an admixture of ſeveral drachms of this white, and three drachms of copperas or more, if they deſire the colour to be deeper.

Moſt of theſe colours are mixed up with gum water, for application; with little *ſalt-petre*, ſometimes ceruſs or copperas, but more uſually copperas alone, being firſt diſſolved in the water. Indeed for *porcelains* that are to be quite red, the colour is uſually applied with oil; i. e. with the common oil of the *porcelain*, or another made of the white ſtints.

Theſe colours are laid on upon the veſſels when they have been once baked, but they do not appear till the ſecond baking is over in their proper ſhades or tinges, and ſometimes ſcarce at all.

The black China called *ombam*, is much eſteemed in the Eaſt, and particularly when it is ornamented with gold; this colour looking better with that ornament than any other. The black is always laid on when the *porcelain* is firſt dried, and is prepared by mixing three ounces of the fine deep blue with ſeven ounces of that fine varniſh, which they call *oil of ſtone*. This admixture gives a fine deep black: but the proportion is varied, as the colour is deſigned to be more or leſs deep. When the colour is thoroughly dry, the veſſels are baked, and when this is done the gold is laid on, and the whole is baked again in a particular furnace made for this purpoſe.

The *gold* on this ware is never laid on alone, but managed in the following manner: they grind it in water to a fine powder, and leave it to dry in the ſhade; they then mix with every ten grains of gold one grain of ceruſs, and incorporating the whole with gum-water, they lay it on in the manner of other colours. See GILDING *of China-ware*.

If they would have the black degenerate into blue, they need only add leſs of the blue, and a little of the ceruſs and agate white before deſcribed. They have two peculiar ways of applying the red, beſide the common one, both which require a nice workman, and make the ware come very dear. They call one of theſe *ſalt red*, and the other *blown* RED, which is very rare and of great price.

There is likewiſe a kind of marbled *porcelain*, called by the Chineſe, who are very fond of it, *tſou ware*.

It is generally plain white, ſometimes blue, and has exactly the appearance of a piece of China which had been firſt broken, and then had all the pieces cemented in their places again, and covered with the original varniſh. The manner of preparing it is eaſy, and might be imitated with us. Inſtead of the common varniſh of the China-ware, which is made of what they call oil of ſtone and oil of fern mixed together, they cover this with a ſimple thing made only of a ſort of coarſe agates calcined to a white powder, and ſeparated from the groſſer parts by means of water, after long grinding in mortars. When the powder has been thus prepared, it is left moiſt, or in form of a ſort of cream, with the laſt water that is ſuffered to remain in it, and this is uſed as the varniſh. Our cryſtal would ſerve fully as well as theſe coarſe agates, and the method of preparation is perfectly eaſy.

The occaſion of the ſingular appearance of this ſort of porcelain is, that the varniſh never ſpreads evenly, but runs into ridges and veins. Theſe often run naturally into a ſort of moſaic-work, which can ſcarce be taken for the effect of chance. If the marbled China be deſired blue, they firſt give it a general coat of this colour, by dipping the veſſel into a blue varniſh; and when this is thoroughly dry, they add another coat of this agate-oil. See PARTY-*Colour*.

There are ſeveral other kinds of *porcelains*, but they are ſuch as are rather for curioſity than uſe: the pretticſt are the magic *porcelains*, whoſe colours only appear when filled with water, or ſome other clear liquor. Theſe are made double: the outſide is white, and all laid out in compartments; the inſide is a ſolid cup, of coloured *porcelain*; though the cup is ſometimes of glaſs, which has a better effect than *porcelain*.

The Chineſe called this ſort of china-ware *kiaſſin*, that is to ſay, the concealed blue china.

The art is now in a great meaſure loſt; but there may be ſome gueſs made as to the manner in which it might be done at this time. The veſſels which are to be made in this manner, muſt be very thin: the colour muſt be laid on in the form of fiſh or other animals or figures, on the inſide, after the veſſel has been once baked. After this colour has had time to dry, the inſide of the veſſel muſt have a ſecond coat of the ſame earth, or ſtone-ware, of which the veſſel is made; and over this a varniſh of the common kind. The conſequence of this will be, that the figures of the fiſh, in a very ſtrong colour, will be buried between two coats of the ware, which together form a complete veſſel. The outſide is then to be ground down almoſt to the figures, and when they begin to appear, a new coat of the varniſh muſt be laid over this. The figures will then be obſcure, and ſcarce, if at all perceivable; but on filling the veſſel with water, the tranſparence of the ſides will be taken off, and the liquor will make a ſort of foil behind, which will throw out the figures of the fiſh. This might be done in any ware tolerably clear and tranſparent. The *porcelain* of China would ſucceed better with it; but the pains and nicety required are too great, and all the attempts lately made by them have miſcarried.

The Chineſe make a great variety of figures on the ſurfaces of the vaſes of white china-ware, and there is one kind of this greatly in eſteem among them, in which there are flowers and other figures; yet the ſurface is quite

quite smooth, and the substance extremely thin. The manner of making it is this; they first form the vessel of the finest materials, as thin as they can; then, when they have polished it, inside and out, at the wheel, they put into it a stamp of its own shape, but cut with all these figures: they press this down so firmly on the yet moist vessel, that the impression is received in a very perfect manner; and if the shape of the vessel be at all hurt, they take it to the wheel again to restore it. They then finish it with the knife and scissars; and when they have made it as perfect as can be, they cover it with the fine white varnish within and without. This fills up all the cavities of the impression, and gives a perfectly smooth and even surface; yet the thickness of this varnish in the traces of the figures gives it a different white, and the whole figures are as finely and accurately seen, as if painted on the outside. This is an artifice that might easily be brought to bear among us, and several of our finer wares would make a pretty figure with it.

There are many things practised by the Chinese in their colouring and forming the several kinds of *porcelain*, which may be well brought into use among us, and give a new value to our own wares, even though we should never arrive at their art of making the thing itself. One kind of colouring easily introduced among us, would be what they call *hoan tan hoan*. This produces vessels of great beauty and price, and is done in this manner. The matter, of which the vessels are made, for this purpose, need not be fine; they usually take any of the common vessels baked, without having been varnished, and consequently simply white, and without lustre. When these are intended to be of one simple colour, they need only be plunged into a liquid varnish or oil, as the workmen there call it, coloured with such ingredients as will strike the most lively tinges: but if it is to be coloured in compartments, as is usually the custom with this sort of china, it is to be done by the pencil. The usual way is to paint these in pannels, one green, another blue, and so on, and they make a very agreeable appearance. These requires no more to this, than the laying on the colours tolerably thick with a large pencil; but if the pictures of animals, and plants are to be given, they are to be done with the most permanent colours, and the vessel being again well baked, becomes very beautiful.

The Chinese, who are deceivers in every thing, find the way of cheating very much in regard to this sort of china-ware. They paint the flowers of plants, and some parts of the birds, &c. in very bright colours, after the vessel has been baked. Vermilion is a fine colour, which they often add on this occasion; but they cannot use this before the baking, because it would be destroyed by the fire. These colours which are laid on afterwards cannot last, but soon rub off in the wiping, or using the things; the others last for ever; for they are laid on with the greatest heat of all, the vessels being put into the same furnaces to lay on these, as the other things are baked in for the first time.

Salt-petre, and powder of flints, are generally the things added to the colours thus laid on, to make them penetrate, and run properly. Thus for the fine deep violet colour, which makes the greatest figure of all others on this ware, they mix together equal quantities of the fine ware, the powder of flints and salt-petre, all first powdered separately till perfectly fine; this is tempered with water, and then laid on with the pencil, and though it looks rough at first, it comes out of the furnace of as beautiful a glossy hue as any thing can be conceived. The yellow is made by mixing together three ounces of cerusse, and three ounces of powdered flints, and adding three, four, or more drachms of the red copperas, till the whole is of the proper degree of colour. The white is composed only of powder of flints and cerusse, with a small admixture of the salt-petre, or it will succeed tolerably well without. These are all the particulars necessary to be observed for the making a sort of *porcelain* of great beauty, in which the nature of the ware itself is not concerned; so that it seems easy to imitate it with any of our own wares. Obs. sur les Coutumes de l'Asie, p. 730, &c.

The several kinds of *porcelain* above mentioned, being quite painted, with their several colours, and all the colours dry, are to be polished, to prepare them to receive the oil or varnish; which is done with a pencil of very fine feathers, moistened with water, and pulled lightly over, to take off even the smallest inequalities.

The oiling or varnishing is the last preparation of the *porcelain*, before it be carried to the oven: this is applied more or less thick, and seldomer or oftener repeated, according to the quality of the work. For thin fine *porcelain*, they give two very thin couches; to others one; but that one equivalent to the other two. There is a deal of art in applying the varnish, both that it be done equally, and not in too great quantity. The couches on the inside are given by aspertion, i. e. by calling in as much varnish as is necessary: those on the outside, by immersion, or by plunging the pieces in a vessel of oil.

It must be observed, that the foot is not yet formed, but continues in a mere mass, till the work has been varnished: it is or length finished on the wheel, and when hollowed, a little circle is painted in it, and sometimes a Chinese character. This painting being dry, the foot is varnished, and the work now carried to the oven to be baked.

The varnish they lay on is so thick, that it often hides the colours, till the baking afterwards brings them out again: this is the case with the fine deep blues; we see none on the best china: it is all laid under the coat of white, and the vessel appears plain, till it has passed through the fire again; but then the colour appears deeper than when at first laid on. See HOAICHI.

The china varnishes have been always famous; the manner of making which is said to be as follows: take crude varnish sixty ounces; common water, the same quantity: mix them well together till the water disappears; afterwards put this into a wooden vessel five or six palms long, and two or three broad; mix them together with a wooden spatula, for a while day in the summer's sun, for two days if in winter, and afterwards keep it in an earthen vessel, covered with a bladder. The water will not separate again: this is called *the sun varnish*.

The oil of wood, called by the Portuguese *oracle da pao*, is made in the following manner: take twenty ounces of that oil, which they call oil of wood; and ten drachms of the oil of the fruit; boil these a little together, and the oil will look yellow: then let it cool, and add to it five drachms of quick lime powdered. To make the first grounds called *camisera*, take swine's blood and quick lime powdered, of each an equal quantity; spread this mixture upon the wood, and when it is dry, smooth it with pumice-stones.

To make the black varnish: take of the varnish prepared in the sun sixty ounces; stone black alum (supposed to be a sort of copperas) dissolved in a little water, three drachms; and seventy drachms of lamp oil, called by the Portuguese *azeite de Cangilon*. These things are all to be mixed together in a wooden vessel, putting the lamp-oil in at wine, and stirring the whole together with a wooden spatula.

The pitch-coloured varnish is made in the following manner: take oil of wood, crude, forty drachms, called *da pao*; of the lamp oil, called *da Cumka* crude, forty drachms; mix them together in the sun in a wooden vessel, in the same manner as the common varnish and water are ordered to be mixed in the first process.

To make the red varnish: take ten drachms of cinnabar, twenty drachms of prepared varnish, and a little lamp-oil; mix them all together.

To make the yellow varnish: take of the yellow colour ten drachms, prepared varnish thirty drachms, a little lamp-oil; mix all together.

To make a varnish of a musk colour: take of the red varnish ten drachms, and of the black varnish four drachms; mix them well together. Philos. Transact. N° 261. p. 524.

These are the accounts sent to the great duke of Tuscany by the Jesuits in China: Dr. William Sherard communicated them to the Royal Society; and to render the accounts useful to the world, he presented with them the several substances mentioned; these are deposited in the museum of the society, and may serve as instructions to all who are curious in this art.

The Chinese have of late years discovered a new kind of varnish for their ware: they call this *tshirwen*, that is to say, the brownish gold varnish; it is of the colour of the brown images, or of what we call coffee colour. The novelty of this has made it much esteemed: it is made in the manner of all their other varnishes, by dissolving the finer part of an earthy substance in water. The substance which they make it of is a common yellow earth: this they dissolve in water, and letting the coarse parts settle, they pour off the yet thick liquor, and what afterwards subsides from this is the pure and fine part, which they keep in form of a soft pulse, or thick cream. They use this only to the thinnest and most delicate *porcelain* ware.

The manner of using it is this: they mix a quantity of this fine sediment with so much water as renders it thin and liquid, like the common varnish: this and the common kind are to be used together, so that care must be taken that they are nicely of the same degree of thickness: this the workmen try by dipping a petunse or brick of their earth into both, and seeing which comes out most covered, that which lies on the thickest, is to be diluted with more water, or the other to be heightened with more of the earth, to bring them to the same standard.

They

They are both judged to be sufficiently liquid when they enter the pores of the petunse. They then mix some of the *oil of* FERN ashes and lime, along with the brown varnish, and add as much of this mixture to the common varnish as they find upon trial will give such a colour as is required. The common proportion for the brown colour most esteemed at present, is two pints of the brown varnish to eight pints of the common; and to four pints of this mixture they add one pint of the varnish, or oil of fern. It might puzzle a stranger to their terms, to understand what these people meant by oil; but it is a word with them in use for any thing liquid, and they call all their varnishes so, though made of the powders of earths and stones mixed with water. They apply this varnish to the vessels by dipping them into it, and so completely covering them inside and out before they put them into the oven; and the baking gives a great brightness to the colour. This is the nicest part of the whole manufacture of the *porcelain*, and other wares of that kind. The varnishes used by the Chinese are two; the one they call *oil of stones*, the other *oil of fern*; which see. They mix these together, and with great caution and delicacy apply them to the vessels all over equally, with a steady hand and a fine pencil.

PORCELAIN, *baking or melting of.* There are two kinds of ovens used in baking *porcelain*; large ones, for works that are only used to come to the fire once, which is the common way; and small ones, for such as require a double baking.

The large ones are two Chinese fathoms deep, and almost four wide. They are formed of a mixture of three earths; one whereof, yellow and common, makes the *kaolin*; the two others are scarcer, and dug out of deep mines, wherein people can only work in winter. One of them, called *kaotou*, is a very strong stiff earth; the other *youtou*, oily.

The sides and roof of the ovens are so thick, that one may lay the hand on them, when the fire is at its height, without danger of burning. At the top of the dome, which is in form of a tunnel, is a large aperture, to give vent to the flames and smoke, which mount up incessantly, as soon as fire is once set to the oven: beside the principal aperture, there are four or five small ones around; which, by being opened and shut, serve to augment or diminish the heat: like the holes in the chemists furnaces, called *registers*. The hearth, which takes up the whole breadth of the oven, is placed in front, precisely against the opening of the door, and is two or three feet deep, and two broad; people passing over it on a plank, to go into the furnace to range the *porcelain*. As soon as the fire is lighted, the door is walled up, only leaving an aperture for the conveyance of wood. Lastly, the bottom of the oven is covered with sand, wherein part of the first *porcelain* cases are buried. The oven itself is usually placed at the extremity of a long, narrow vestibule, which serves in lieu of bellows; the cold air and wind being thus driven directly in the face of each oven.

Each piece of *porcelain* of any note, is disposed, in the furnace, in its peculiar, separate case, or coffin. Indeed, as to tea-dishes, &c. the same case serves for several. The cases are all of the same matter with the oven; they have no lids, but serve each other mutually; the bottom of a second case sitting into the aperture of the first; and thus successively to the top of each column. Each coffin, which is usually of a cylindrical form, that the fire may communicate itself more equably to the *porcelains* inclosed, has, at bottom, a little lay of very fine sand, covered over with dust of kaolin, that the sand may not stick to the work; and care is taken, that the *porcelain* may not touch the sides of the case. In the larger cases, which hold the small pieces, they leave the middle vacant, in regard *porcelains* placed there would want the necessary heat. Each of these little pieces is mounted on a little massive of earth, of the thickness of two crowns, covered with powder of kaolin.

P. d'Entrecolles observes, that the *porcelains* are put in cases, to prevent any diminution of lustre from the too violent effect of a naked fire; adding, that it is owing to those thick veils, that the beauty, or, as he calls it, the complexion of the *porcelains*, is not tanned by the heat of the fire.

As fast as the cases are filled, a workman ranges them in the cavity of the furnace; forming them into piles, or columns, whereof those in the middle are, at least, seven feet high: the two cases at the bottom of each column are left empty, because being partly sunk in the sand, the fire has the less effect on them; and, for the same reason, the uppermost one is left empty. In this manner is the whole cavity of the oven filled with columns, excepting that part precisely under the grand aperture. In ranging the cases, they observe always to place the finest piles of *porcelain* in the centre, the coarsest at the bottom, and those that are high-coloured, and consist of as much petunse as kaolin, and wherein the worst oil is used, at the mouth.

These piles are all placed very near one another, and are bound together at top, at bottom, and in the middle, by pieces of earth, in such manner as that the flame may have a free passage among them, and insinuate equally on all sides: in which a great part of the workman's art lies, and on which the perfection of the *porcelain* much depends. Another thing to be observed is, that an oven must never be set altogether with new collins; but half one, half the other: the old ones at the bottoms and tops of the pile, and the new ones in the middle. Indeed it were better to have them all burnt in an oven apart, before they come to be used for *porcelain*, as was anciently done. The cases, our author observes, are brought ready prepared, from a large village on the river, a league distant from Kingtetching. Before they are burnt, they are yellow; and afterwards of a dark red.

When the oven is filled, they wall up the door, only leaving a little aperture for the throwing in of little pieces of wood, a foot long, but very slender, to keep up the fire: it is then heated, by degrees, for the space of a day and night; after which, two men, who relieve one another, continue to throw in wood, without any intermission. To know when the *porcelain* is baked enough, they open one of the lesser holes of the oven, and, with a pair of tongs, take off the lid of one of the piles. If the fire appears very brisk and clear, and the piles equally inflamed, and especially if the colours of the *porcelain* that is uncovered, dart forth a noble lustre: the coction is sufficient, they discontinue the fire, and wall up what remained of the door of the furnace.

If the oven be only filled with small *porcelain*, they take them out twelve or fifteen hours after the fire is extinct: if it be filled with larger, they defer opening it for two or three days. In this the modern practice differs from the ancient; wherein the door was not opened till after ten days for the large pieces, and five for the small ones. One thing very surprising, and almost inconceivable, P. d'Entrecolles observes, is, that there are never found any ashes on the hearth of the oven, what quantity of wood soever is consumed. He adds another thing, which with him passes for equally strange, that the workmen employed about the furnaces, flake their thirst by continually drinking hot tea, with salt dissolved in it.

The Chinese make another kind of *porcelain*, which they paint and bake twice; and for this second baking they have a kind of little ovens on purpose. These ovens, when very small, are made of iron; or otherwise of a kind of bricks an inch thick, a foot high, and half a foot broad, made of the same earth with the *porcelain cases*. The biggest of these ovens do not exceed five feet in height, and three in diameter; and being made much in form of bee-hives, the bricks are arched a little, to form the cavity the better. The hearth is of earth half a foot high, formed of two or three ranges of bricks; and on this massive is the oven built. Around the oven at the distance of about half a foot, is raised a shell of common bricks, joined to the oven itself by a kind of arcboutant of earth, which serves to strengthen it. They usually build four or five of these ovens at equal distances from each other. At the bottom of the shell are holes to give air to the fire when lighted: at top is an aperture, which they cover up with a piece of the baked earth, when the *porcelains* are laid in the oven.

The *porcelains*, here, are not inclosed in coffins, as in the common ovens; the oven itself serving that purpose, and being so exactly closed, that they receive no other impression of the fire, but that of the heat of the charcoal disposed in the hearth, at the bottom of the oven, as well as at top of the vault, and in the interval between the oven and the shell, or brick-wall.

To prepare the *porcelains* for a second baking, they must have had their varnish in the common manner, and have passed the great oven: in this state they are painted with various colours, after which, without giving them any new varnish, they are ranged in piles in the little oven; setting the little ones over the larger, in form of pyramids. The Chinese are very artful in their disposition of these, arranging them in the most compact manner, and putting the little ones within the great ones; but great care is also necessary, that the vessels do not touch one another in the parts where they are painted, for the consequence of that would be the spoiling of both vessels, as the colours would run together. The bottom of one vessel may generally be placed on the bottom of another, though both are painted, because the rims are not painted, and they keep the painted parts from touching one another. High and narrow vessels, such as chocolate-cups, and the like, are very troublesome on this occasion. The method the

Chinese workmen take with them, is this: they place a range of them, so as to cover the whole bottom of the furnace, and they cover this with a thin bed of broken china-ware, over which they place another row of the cups, and so on to the top, where they lay on no covering: they never bake any thing else with these cups, when they are of this kind of twice-baked *porcelain*.

This second baking is sometimes intended to preserve the lustre of the colours the better, and at the same time to give them a kind of relievo; but, more usually its design is to hide defective places, by covering them over with colours; but the artifice is easily found out, by passing the hand over them.

When the workman judges his *porcelains* enough baked, he takes off the piece that covers the aperture; takes out the charcoal; and, when the oven is cold, the *porcelain* is so too.

How beautiful soever the modern *porcelain* may be, the taste for antiquity, which reigns in China, as well as in Europe, gives the ancient *porcelain* a value far above that of the modern.

It must be owned, the ancient seems finer as to the matter, more perfect as to the baking, and of a more pleasant cast, both as to the white of the ground, and the other colours; yet, it is certain, the most able and discerning may be deceived herein: and there are workmen who make it their business to counterfeit the ancient *porcelain*, called *kutong*, in the modern.

The matter of the false kutong is a softish yellowish earth, found near Kingtetching. There is nothing particular in the first part of the process, except that they are made thicker, and that they are varnished with an oil drawn from the yellow-stone, mixed with the common oil, which gives them a kind of sea-green hue. When taken out of the oven they throw it into a fatty broth, made of capons, &c. in which they boil it a second time; they then bury it in the filthiest sink they can find, for a month or six weeks, or more, according as they would give it the greater appearance of antiquity. Besides their thickness, and their colour, these false antiques resemble the true ones in this, that they do not resound when struck, nor even give the least buz, when held to the ear.

Notwithstanding the vast quantity of *porcelain* made in almost all the provinces of the empire of China, they still continue very dear, though not near so dear as anciently. The Chinese annals tell us of times wherein a single urn cost ninety or a hundred crowns on the spot. What chiefly occasions the extraordinary price of this commodity, especially in Europe, is, beside the great profits of the merchant in Europe, and their factors in China, that it rarely happens an oven succeeds throughout; that it is frequently quite spoiled, so that, upon opening it, in lieu of fine *porcelains*, is found a hard unformed mass, into which both the *porcelains*, and their coffins, are converted, either by excess of heat, or some ill qualities in the matter.

Another reason of the dearness of *porcelain* is, that the ingredients it is made of, and the wood wherewith it is burnt, grow more and more scarce. One may add a third reason for the excessive price of *porcelain* to the Europeans; and it is this: that most of those sent to Europe are formed on new models, frequently very capricious, and difficult to succeed in; which yet, for the smallest defects are turned on the manufacturer's hands: and he, not being able to dispose of them to the Chinese, because not to their taste, nor to their use, is forced to charge the *porcelain* he delivers the higher, to pay himself for those refused.

The art of making *porcelain* is one of those in which Europe has been excelled by oriental nations. However, earthen wares have been made, for several years past, in different parts of Europe, so like the oriental, that they have acquired the name of *porcelain*. The first European *porcelains* are said to have been made in Saxony and in France; and afterwards in England, Germany, and Italy; all of which differed from those of Japan and China, but each possessing its peculiar character. The first person, who seems to have made this manufacture the object of scientific attention, was M. Reaumur; and he communicated his researches in two Memoirs to the Academy of Sciences, in 1727 and 1729. Having broken pieces of the Japanese, Saxon, and French *porcelains*, he examined the difference of their grains or internal structure. The grain of the Japanese *porcelain* appeared to him to be fine, close, compact, moderately smooth, and somewhat shining. The grain of the Saxon *porcelain* was found to be still more compact, not granulous, smooth, and shining like enamel. And the *porcelain* of St. Cloud had a grain much less close and fine than that of Japan, shining little or not at all, and resembling the grain of sugar. In order to determine their difference still further, he exposed them to a violent heat; and found that the Japanese *porcelain* was unaltered by the fire, and all the European *porcelains* were melted. This essential difference suggested to him the most just and regular idea, that has yet been formed of the *porcelain* or china-ware, viz. that it is a half vitrified substance or manufacture, in a middle state between the common baked earthen ware of our vulgar manufactures, and true glass. This is the essential and distinctive character of *porcelain*, and it is only by considering it in this light, that we are to hope to arrive at the perfect art of imitating it in Europe. The determining the due degree of heat for the baking the china-ware, and the finding out the proper time it should remain in that heat, are two very essential points in the manufacture of this elegant ware. Perhaps our English attempts to imitate it would be brought nearer the perfection we are aiming at, by a just regard to these particulars, than by many other less material articles, about which we seem more solicitous.

This attempt is to be made on these principles in two different manners: the one by finding some appropriated matter on which fire acts with more than ordinary strength in the time of its passing from the common baked state of earthen ware into that of glass. The other is, to compose a paste of two substances reduced to powder, the one of which shall be of force to resist a very violent fire, so as not to become vitrified in it; and the other, a matter very easily vitrifiable.

In the first case, the matter is to be taken out of the fire at the time when it is imperfectly vitrified; and in the other, the compound mass is to remain in the furnace till the one substance, which is the more easily vitrifiable, is truly vitrified; and being then taken out, the whole will be what *porcelain* is, a substance in part vitrified, but not wholly so.

The first method is that by which the European *porcelain* has generally been made, and though that of St. Cloud, and some other places, has been very beautiful, yet it is always easy to distinguish even the finest of it from the china-ware, and the nature of the two substances appears evidently different: these owing all their beauty to their near approach to vitrification, are made to endure a long and violent fire, and are taken from it at a time when a very little longer continuance would have made them perfect glass: on the contrary, the china-ware being made of a paste, part of which is made of a substance in itself scarce possible to be vitrified, bears the fire in a yet much more intense degree than ours, and is in no danger of running wholly into glass from it.

The two substances used by the Chinese are well known by the names of *petunse* and *kaolin*, and on examining these it appears very evident, that we have in Europe the very same substances, or at least substances of the very same nature, and capable of being wrought into a *porcelain* equally beautiful and fine. Mem. Acad. Scienc. Par. 1739. See KAOLIN and PETUNTSE.

These are the two different semi-vitrifications, on one or other of which all the European manufactures have hitherto been founded; and it is easy from the knowledge of these principles to determine, on breaking a piece of the china of any of our manufactures, by which of the two processes it is made. If it is made by seizing the half-vitrified mass of a substance which would soon after have been wholly vitrified, then the putting it in a crucible, into an equal degree of fire, will soon turn it wholly into glass. This is the case of most of our European *porcelains*; but if it be made of two ingredients, the one of which is not vitrifiable, or at least not by such fires, then the matter will melt, but will not vitrify: this is the case with the Chinese *porcelain*, which if kept in fusion a long time, yet when cold is china-ware still; so that this is evidently made of two such different ingredients.

Besides these methods, there is yet another, of late invention, which makes a very beautiful china; and which, if it does not afford vessels equal to those of China, yet will afford them nearly approaching to these, and at a considerably smaller price. This method consists in reducing glass to china. See GLASS-*porcelain*.

The author of the Chemical Dictionary observes, that M. Reaumur has erroneously confounded the Saxon *porcelain* with the other fusible *porcelains* in Europe. For though it contains, as every *porcelain* does, particularly that of China and Japan, a feible substance, which has been completely fused in the operation of baking, and to which it owes its density and internal lustre; yet it contains also a large quantity of a substance absolutely unfusible, from which it receives its admirable whiteness, its firmness and solidity, during the baking, supplying the place of the oriental kaolin, and contracting its dimensions in a considerable degree, while it incorporates with the fusible substance. He has actually found, that this *porcelain* cannot be fused, unless by a fire capable also

of

of melting the beſt Japaneſe *porcelain*. And he obſerves, that it is ſuperior to the oriental in the ſmoothneſs, luſtre, and leſs granulous appearance of its internal ſurface. The manufacture of Saxony has been long eſtabliſhed: and that at Meiſſen, a few miles from Dreſden, has produced *porcelains* painted and enamelled in ſuch perfection, that they have been reckoned more beautiful and ſold at a higher price than even thoſe of China.

The invention is ſaid to have been owing to an alchemiſt, called Botticher, who, being confined in the caſtle of Konigſtein by the king of Poland, on a ſuſpicion of being maſter of the philoſopher's ſtone, had leiſure ſufficient, not indeed to make gold, but to invent a ware, which by the excellence and value of it conſiderably enriches the country. He died in 1719, but it ſeems that he only invented the white ſort; the art of making brown and blue *porcelain* not having been diſcovered till the year 1722.

Porcelain is alſo made at Vienna, Frankendal, and lately in the neighbourhood of Berlin: all which are made of the ſame kind of materials with thoſe of Saxony. In Italy there are alſo manufactures of *porcelain*, at Naples and Florence. In France they have had manufactures of this kind for many years: *porcelain* was made at St. Cloud, and in the ſuburb of St. Antoine at Paris, before M. de Reaumur's publication; but though beautiful, it was of the vitreous and fuſible kind. Since that time, conſiderable manufactures of it have been eſtabliſhed at Chantilly, Villeroi, and Orleans, the *porcelains* of which have a diſtinguiſhed merit: but thoſe produced in the king's manufactory at Sevres, are ſaid to do greateſt honour to France, on account of their ſhining, white, beautiful glazing, and coloured grounds.

M. Guettard, who has lately publiſhed an account of his diſcoveries in the Memoirs of the Academy of Sciences for the year 1765, ſeems to have been one of the firſt, who, ſince M. Reaumur, found in France a kaolin and petunſe of the ſame nature as the Chineſe; the former is a white argillaceous earth filled with mica; the latter a hard quartroſe ſtone. The count de Lauraguais has alſo ſo far ſucceeded in his attempts in this way, that ſome pieces, preſented by him in 1766, to the Academy of Sciences, were declared to reſemble the *porcelains* of China and Japan in ſolidity, grain, and unfuſibility, more than any other that had been made in that country, though it wants the whiteneſs and luſtre obſervable in the ancient Japaneſe *porcelain*.

We have alſo had for many years, ſeveral manufactures of *porcelain* in England; that of Cheliea is ſcarce inferior to thoſe of Saxony and France; but being calculated more for ornament than uſe, it is dear and of no very general advantage. The *porcelains* that are produced in our other manufactories are ſold at a much cheaper rate than any that is imported; but, except that of Worceſter, they all wear brown, and are ſubject to crack, eſpecially in the glazing, by boiling water: the Worceſter *porcelain* has a good body hardly inferior to that of eaſtern china; it is equally tough, and its glazing never cracks or ſcales off.

With reſpect to the method of manufacturing *porcelain*, it may be obſerved, that the baſis of that which is fuſible and vitreous, and which may be called falſe *porcelain*, is a FRIT; formed of a mixture of ſand or of powdered flints, with ſalts capable of diſpoſing them to fuſion, and of giving them a great whiteneſs by means of a ſufficient heat.

This frit is mixed with as much of a white tenacious earth of an argillaceous or marly nature, as is ſufficient to make it capable of being worked upon the wheel: the whole mixture is well ground in a mill, and made into a paſte, which is formed either upon the wheel or in moulds, into the various pieces required. Each of theſe pieces, when dry, is put into a caſe made of earthen ware; which cafes, called by the Engliſh potters SEGGARS, are to be ranged in piles one upon another, in a furnace or kiln, which is to be filled with them to the roof. The furnaces are chambers or cavities of various forms and ſizes, and are ſo diſpoſed, that the fire-place is on the outſide oppoſite to one or more openings, which communicate within the furnace. The furnace is gradually heated by increaſing the fire till the *porcelain* is baked, or has acquired its proper hardneſs and tranſparency, which is known by taking out and examining pieces, placed for that purpoſe in cafes which have lateral openings. When the *porcelain* is ſufficiently baked and gradually cooled, it reſembles white marble, not having a ſhining ſurface, which it is to acquire by the operation of glazing. This muſt be adapted to the nature of the *porcelain*, i. e. to the hardneſs and denſity of the ware, the ingredients of compoſition, &c. The ſeveral glazings are prepared by previouſly fuſing together all the ſubſtances of which they conſiſt, ſo as to form vitreous maſſes, which are to be ground by a mill into a fine powder, and this powder is to be mixed with a ſufficient quantity of water or other liquor, ſo that the mixture may have the conſiſtence of cream. The pieces of *porcelain* are to be covered with a thin ſtratum of this matter, and when very dry to be put into the furnace as before, and continued there till the glazing be well fuſed; which requires a leſs fire than baking the paſte. And thus the pieces of *porcelain* that are to remain white are finiſhed. The glazing uſed by the Chineſe is ſaid to be formed of the oil of petuntſe and the oil of lime, deſcribed in the preceding part of this article: that uſed in a conſiderable manufactory of *porcelain* in our own country, is formed of twenty pounds of the fineſt white ſand or calcined flints, eighteen pounds of red-lead, ten pounds of pearl-aſhes, and four pounds of common ſalt decrepitated. The two firſt ingredients, being well levigated together, are mixed with the two latter, and the compound fuſed to vitrification. It is then to be reduced in a flint, agate, or porphyry mortar to an impalpable powder, which is tempered with water to the proper conſiſtence for painting.

The colours applied to *porcelain* are the ſame as thoſe uſed for ENAMEL painting, and conſiſt of metallic calces bruiſed and incorporated with a very fuſible glaſs. Crocus of iron affords a red colour; Caſſius's precipitate of GOLD makes the purple and violet; copper calcined by acids and precipitated by an alkali, gives a fine green; zaffre makes the blue; earths ſlightly ferruginous, produce a yellow, and, laſtly, brown and black colours are produced by calcined iron, together with a deep blue of zaffre. Theſe colours, ground with gum water or oil of ſpike, are to be employed for the painting of the *porcelain* with deſigns of flowers and other figures.

For GILDING, a powder or calx of gold is to be applied in the ſame manner as the coloured enamels. The painted and gilded *porcelains* are to be expoſed to a fire capable of fuſing the glaſs with which the metallic colours are mixed; by which means they are made to adhere, and acquire a gloſs equal to that of the GLASS. The ſhining appearance of the gold is produced by burniſhing with a blood-ſtone.

Dr. Lewis (Com. Phil. Techn. p. 627.) obſerves, that glaſs of lead and glaſs of antimony make a gold-coloured glazing for *porcelain* and earthen-ware. The fineſt gold glazing is ſaid to be made with an addition of ſilver. A glaſs of lead is prepared by melting minium or litharge with a third or fourth part of its weight of powdered flint. This yellow glaſs, reduced into fine powder, is either ſprinkled on the *porcelain* made red hot, or mixed with beer, or other glutinous liquids to a due conſiſtence, and applied with a pencil: the ware is then placed in the furnace, under a muffle, till the glaſs begins to melt, which is known by its gliſtening; after which, while warm from the fire, it is moiſtened with a diluted ſolution of ſilver, and baked again. Or, the powdered glaſs of lead is moiſtened with the ſilver ſolution, then melted, and the glazing of the ware finiſhed in one proceſs, by applying on it this compound glaſs. After the baking, the glazed veſſels, while ſtill red hot, are held over the ſmoke of burning ſtraw, &c.

The operations for the unfuſible *porcelain*, and alſo for ſuch as are of the nature of ſtone-ware, are ſomewhat more ſimple. The ſand and ſtones which enter into their compoſition are to be ground in a mill: the earths or clays are to be waſhed; the materials are to be well mixed and formed into a paſte; the pieces are firſt rudely formed upon a potter's wheel; and when dry or half dry, they are turned again upon the wheel, and their form is made more perfect; they are then placed in the furnace, not to bake them, but only to apply a ſufficient heat to give them ſuch a ſolidity that they may be handled without breaking, and may receive the glazing. As the pieces of *porcelain* after this ſlight heat are very dry, they imbibe water readily. This diſpoſition aſſiſts the application of the glazing. The vitrifiable or vitrified matter of this glazing, which has been previouſly ground in a mill, is to be mixed with ſuch a quantity of water, that the liquor ſhall have the conſiſtence of milk. The pieces of *porcelain* are haſtily dipt in this liquor, the water of which they imbibe, and thus on their ſurface is left an uniform covering of the glazing materials. This covering, which ought to be very thin, will very ſoon become ſo dry, that it cannot ſtick to the fingers when the pieces are handled.

The pieces of this *porcelain* are then put into the furnace to be perfectly baked. The heat is to be raiſed to ſuch a height, that all within the furnace ſhall be white, and the caſes ſhall be undiſtinguiſhable from the flame. When, by taking out ſmall pieces, the *porcelain* is known to be ſufficiently baked, the fire is diſcontinued, and the furnace cooled. If the baking has been well performed, the pieces of *porcelain* will be found by this ſingle operation

to be rendered compact, sonorous, close-grained, moderately glossy, and covered externally with a fine glazing. The painting and gilding of this *porcelain* are to be executed in a manner similar to that already described. Chemical Dict. art. *Porcelain*. See POTTERY, and DELF-*ware*.

PORCELAIN-*shell*, *porcellana*, or *concha veneris*, in *Natural History*, the name of a genus of shell fish, the characters of which are these: they are of the univalve kind, and have for their mouth a long and narrow slit, dentated on each side, and of a conglobated, oblong, gibbose, or umbonated form.

These shells are classed in the Linnæan system under the genus of CYPRÆA, including forty-four species, whose characters are, that the animal is a slug; the shell univalve, fish-oval, and blunt at each end; and the aperture of the length of the shell longitudinal, linear, and toothed.

This genus of shells originally had the name of *porcellana* and *concha veneria* from the resemblance of its mouth to the *pudendum muliebre*, called by some of the Roman writers, *porculus* and *porcellus*, and always alluded to under the word *Venus*. We have of late so far misunderstood the name as to suppose it derived of the word *porcelain*, from an imagination, that the Chinese *porcelain*-ware was made of it. Gesner has fallen into the opinion, and Aldrovand seems to have been mistaken in regard to its other name, *concha veneria*, supposing it so called because of its beauty, and therefore sacred to Venus. Rondeletius calls it the *remora Mutiani*; and the murex of the same author. Aldrovand. de Test. l. 3. p. 352. Gesner, Rondelet. de Test. l. 2. p. 102.

These shells are current in several parts of Asia, Africa, and America, as money; and they have been prescribed, pulverized, in medicine. See CONCHA *Veneris*.

The name *concha veneria* may be apt to create confusion, because there is another shell of a very different kind, a bivalve, called CONCHA *Veneris*. This genus is therefore much better distinguished by the name *porcellana*. There is a prodigious difference among the species of this genus; some are heavy, others very light; some have the mouth placed in a longitudinal, others in a transverse direction.

The gibbous *porcelain* is a very remarkable species, as is also the egg-*porcelain*, which has two buttons at the extremities; and the egg-*porcelain* called the *navel* is not less remarkable than these: this has, instead of a button, a long beak at each end.

The mouth of the *porcelain* must be narrow and oblong; this is the great characteristic, and is usually dentated either on both sides or on one.

The species of *porcelain* are so numerous, that it may be proper, in the enumeration of them, to arrange them under some regular heads. See *Tab. of Shells*, N° 16.

Some *porcellanæ* are conglobated, and thick; of these the cabinets of the curious afford us sixteen species.

Some again are thick and of a pyriform figure; of these we have twenty-one; and others are gibbous, of which we have five species. Hist. Nat. Exclusa. p. 308.

PORCELLIONES, in the *Materia Medica*, a name given by some to the MILLEPEDES.

PORCELLO, in the *Glass Trade*, the instrument with which the workmen, after having made the opening for the bowl of a drinking glass or other such vessel, with his paliage, widens and renders it more capacious at pleasure.

PORCELLUS *Gallicinnus*, in *Medicine*, the name of a disease to which the people of Hungary and Poland are very subject.

It is a hard tumor of the belly, attended with wind and violent pains. It it truly an infarction of the SPLEEN, and is to be cured by aperitives. Philos. Transact. N° 243.

PORCELLUS *Indicus*, in *Zoology*, a name given by authors to the animal called with us the GUINEA *pig*.

PORCH, *atrium*, a kind of vestibule, supported by columns, much often at the entrance of the ancient temples, halls, churches, &c.

In the ancient architecture, a *porch* was a vestibule, or a disposition of insulated columns, usually crowned with a pediment, forming a covert place before the principal door of a temple, or court of justice. Such is that before the door of St. Paul's, Covent-garden, the work of Inigo Jones.

When it had four columns in front, it was called a *tetrastyle*; when six, *hexastyle*; when eight, *octostyle*; when ten, *decastyle*, &c. Vitruvius calls it *pronaos*; Pollux, *propylæum*; when finer than ordinary, the ancients call it, also, *prospylæum*.

PORCO a name by which some authors have called the fish more usually known by the name of *capriscus*, supposed to be the *porcus* of Pliny. See GOAT-*fish*.

PORCUPINE, *hystrix*, in the Linnæan system of *Zoology*, a distinct genus of animals of the order of *glires*, the characters of which are, that the creatures of it have two cutting teeth in each jaw, eight grinders, and the body covered with long, hard, and sharp quills; to which Mr. Pennant adds, that the upper lip is divided. Linnæus enumerates four species.

The *crested porcupine* is so called from a long crest on the top of the head, reclining backwards, formed of stiff bristles; between the quills, which are sharp at the ends, and varied with black and white, there are a few hairs; the head, belly, and legs are covered with strong bristles, terminated with soft hair of a dusky colour; the whiskers are long; the ears like the human; the toes are four before, and five behind; the tail short, and covered with quills. This animal inhabits India, Tartary, Persia, and all parts of Africa; it is found wild in Italy, and brought into the markets at Rome, where it is eat; but it is not originally a native of Europe. It is a harmless animal, lives on vegetables, sleeps by day, and feeds by night; and when angry runs its nose into a corner, erects its spines, and makes a snorting noise. These animals produce a BEZOAR. Pennant. See *Tab.* IV. *Quadrupeds*, N° 49.

PORCUPINE, the *American*, or *Brasilian*, the *hystrix petasensis* of Linnæus, called also *cuandu*, and by Hernandez *tlopotzatzin*, has a short blunt nose, long white whiskers, beneath the nose a bed of small spines, and the top of the head, back, side, and base of the tail covered with spines, about three inches long, white, and barred near their points with black, between which the skin is naked: on the breast, belly, and lower part of the legs, it has dark-brown bristles; its feet are divided into four toes with very long claws; the tail is eight inches long, tapering towards the end, and for the last ten inches almost naked. This species inhabits Mexico and Brasil.

It climbs trees, but slowly and with difficulty, for want of a heel or hinder toe. It usually twists its tail about a bough to keep it safe from falling. It makes a grunting like that of a hog. It feeds on poultry, and its flesh is very well tasted. See *Tab.* IV. *Quadrupeds*, N° 50. Ray and Pennant.

PORCUPINE, the *Canada*, or *hystrix dorsata* of Linnæus, has short ears hid in the fur; the head, body, legs, and upper part of the tail are covered with soft, long, dark brown hair; the upper parts of the head, back, body, and tail are furnished with many sharp strong quills, hid in the hair; the under-side of the tail is white; the fore feet have four toes, and the hind feet five, armed with long claws; the body in form resembles that of the beaver, but is not half as large; the tail is about six inches long. This animal inhabits North America, as high as Hudson's-bay, nells under the roots of large trees, and climbs the boughs; it feeds on wild fruits and barks of trees. The Indians esteem its flesh wholesome and agreeable; and use the quills for ornaments. See *Tab.* IV. *Quadrupeds*, N° 51.

The *long-tailed porcupine*, or *hystrix macroura* of Linnæus, called by Seba *porcus occidentalis*, has long whiskers, bare naked ears, large bright eyes, a short thick body, covered with long stiff hairs as sharp as needles, of different colours, according to the incidence of the light upon them; feet divided into five toes, the tail as long as the body, with a thick tuft at the end, and the bristles appearing as if they were jointed, transparent, and of a silvery hue. This species inhabites the islands of the Indian Archipelago, and lives in the forests. Pennant.

PORCUPINE-*fish*, *hystrix*, in *Ichthyology*, a species of *ostracion*, in the Artedian system, but of the *diodon*, belonging to the class of *amphibia nantes*, according to the Linnæan distribution. Its usual size is between twelve and twenty inches in length; it is very thick, and covered, instead of scales, with a whitish cutaneous skin, every way beset with strong sharp thorns, the bases of each of which has two other smaller ones buried under the skin; the opening of the mouth is very large, with rough tagged lips, and two broad bones in the place of teeth, one placed above, and the other below, both which are arched and a little prominent, as is also the whole mouth; the eyes are large, the eye-lids elevated, and armed with four thorns, which are from one to three inches in length; the sides having the longest, and their length gradually shortening towards the back and belly; the belly is white, and the back brown, sported with black, as are also the sides. This species is found near the Cape of Good Hope. Chil. Exot. lib. vi. cap. 21. See *Tab.* IV. *Fish*, N° 38.

PORCUS *muricatus*, in *Zoology*. See PORCUPINE.

PORCUS *fluviatilis*, in *Ichthyology*, a name given by the old Latin authors to the fish we at this time call the CERNUA and *aurata*, and in English the RUFFE.

PORCUS *Guinnæus*, in *Zoology*, the name of the Guinea HOG. This creature is of the same shape and make with our

hog, and of a reddish tawny colour; its head, however, is somewhat more depressed than in our kind, and its ears longer, and running into narrow points; its tail is naked, but so long, that it reaches almost to its heels; its hair is all short and thining; it has no bristles on the back, but only near the rump; and on the shoulders the hair is a little longer than elsewhere. It is a tame domestic creature. Ray.

PORCUS *marinus*, or *sea-hog*, in *Ichthyology*. See PORPESSE.

PORE, formed from *πορος*, *aperture*, or *duct*, a little interstice between the particles of matter which constitute bodies; either empty, or filled with some insensible medium.

Condensation and rarefaction are only performed by closing and opening the *pores*.

The transparency of bodies is usually supposed to arise from their *pores* being directly opposite to one another. The matter of insensible perspiration is conveyed through the *pores* of the cutis.

Sir Isaac Newton shews, that bodies are much more rare and *porous* than is commonly believed: water, e. gr. is nineteen times lighter, and consequently rarer, than gold; and gold itself is so rare, as very readily, and without the least opposition, to transmit magnetic effluvia, and easily to admit quicksilver into its *pores*, and to let even water pass through it: for a concave sphere of gold hath, when filled with water, and soldered up, upon prelling with a great force, let the water squeeze through it, and stand all over its outside, in multitudes of small drops like dew, without bursting or cracking the gold. See COMPRESSION.

Whence it may be concluded, that gold has more *pores* than solid parts; and, by consequence, that water hath above forty times more *pores* than parts.

The MAGNET transmits its virtues, without any diminution or alteration, through all cold bodies that are not magnetic: as gold, silver, brass, glass, water, &c.

The rays of light, let them be either bodies actually coming to us from the sun, or only motions or impressions upon the medium, move in right lines, and are hardly ever, unless by great chance, reflected back again in the same line, after their impingence upon objects; and yet we see, that light is transmitted to the greatest distances through pellucid bodies, and that in right lines.

Now how bodies should have *pores* sufficient for these effects, may be difficult to conceive, but not impossible: for Sir Isaac shews, that the colours of all bodies arise from their particles being of such a determinate size, or magnitude. Wherefore, if we conceive those particles to be so disposed, as that there is as much porosity as there is of matter; and, in like manner, those particles to be composed of others much less, and that have as much interspersed vacuity, or space, as their quantity of matter amounts to; and so on, till we come to solid particles without *pores*: then, if in any body there be (for instance) three of these sizes of particles, and that the last be of the solid, or least sort; that body will have seven times as much vacuity as solid matter: if four such degrees and the last be least, and solid, that body will have fifteen times as much porosity as solidity; if five such degrees, it will have thirty-one times as much space as solidity; and if six degrees, then it will have sixty-three times as much vacuity as solid matter.

And perhaps, in the wonderful conformation and fabric of natural bodies, there may be other proportions of space to matter, which are to us wholly unknown; whence it is possible there may be yet farther great quantities of interspersed vacuity.

PORES, in *Anatomy*, are certain permeable spaces, between the parts of the skin, whereby we sweat, or perspire, &c. See *Tab. Anat. Myol. fig.* 8. *lit.* d d. *fig.* 9. *lit.* a a, and e.

The *pores* are most remarkable in the hands and feet. By viewing the palm of the hand with a moderate glass, after washing it well, we perceive innumerable little ridges of equal size and distance, running parallel to each other, especially on the tips and joints of the fingers, &c. where they are regularly disposed into spherical triangles, and ellipses.

On these ridges stand the *pores*, in even rows, big enough to be seen by a good eye without a glass; but with one, every *pore* looks like a little fountain; and the sweat may be seen to stand therein, clear as rock water; and as often as it is wiped off, it springs up again.

The *pores* are placed on the ridges, not in the furrows between them; that they might be less liable to be stopped by compression: for the same reason, the *pores* of the hands and feet are larger than the rest; those parts being more used, and pressed, than the rest; and hence, again, there are no ridges on other parts.

These *pores* serve as a convenient outlet for the more noxious parts of the blood, which, by the continual use of the hands and feet, are plentifully brought into them; whence, in hypochondriac and hysteric people, there is a continual burning in the palms and soles.

In the stoppage or constriction of the *pores* of the skin, that disease which we popularly call a *cold*, is commonly supposed to consist; though Dr. Keill maintains a quite contrary opinion, in a dissertation at the end of his Medicina Statica Britannica.

In the Philosophical Transactions we have an instance of a student near Leyden much addicted to astronomy, who spending many nights in star-gazing, had, by the nocturnal wet and cold, so obstructed the *pores* of his skin, that little or nothing exhaled from his body: as appeared hence, that the shirt he had worn five or six weeks was then as white as if it had only been worn one day. In the mean while, a water was collected under the skin, whereof he was afterwards cured.

PORE, *biliary*. See BILIARY *ports*.

PORELLA, in *Botany*, the name of a genus of mosses, the characters of which are these: the capsules contain a powder like those of the other mosses: and they have neither operculum, calyptra, nor pedicle; and their manner of shedding their powder is not by separating into two parts, like those of the polago and lycopodium, but by opening into several holes on all sides. See *Tab.* XV. of *Botany*, N° 17.

Of this genus of mosses there is only one known species; this is called by Dillenius, the plainly pinnated *porella*, and grows in wet places in Virginia, Pensylvania, Maryland, and other parts of North-America.

PORFILIGON, a word used by some of the chemical writers to express the squamæ martis, or the scales of iron which fly off in the smith's hammering of it.

PORISM, PORISMA, in *Geometry*, a theorem, or proposition, so easily demonstrated, that it is almost self-evident.

The word is formed from the Greek *πορισμος*, *perviso*, a thing easy to penetrate or conceive, and which opens the way to something more difficult.

Such, e. gr. is this; that a chord is wholly within the circle.

Porisme stands opposed to *aporisme*, which denotes a proposition so difficult, as to be almost impossible to be demonstrated. Such as the quadrature of the circle is now, and as the squaring of any assigned portion of Hippocrates's lunes formerly was.

The *porisme* coincides nearly with the LEMMA, or assumption.

PORISM, PORISMA, in *Mathematics*, a general theorem, or canon, deduced from a geometrical locus, and serving for the solution of other general and difficult problems. Proclus derives the word from the Greek *πορος*, *I abstract*, and concludes from something already done and demonstrated: and, accordingly, defines *porisma*, a theorem drawn occasionally from some other theorem already demonstrated. In which sense it coincides with what we otherwise call corollary.

The *porisms* of Euclid were contained in three books, and consisted of a curious collection of many things which related to the analysis of the more difficult and general problems: nothing remains in the works of the ancient geometers concerning this subject besides what Pappus has preserved in a very imperfect and obscure state in his mathematical collections.

A *porism*, he says, is that in which something was proposed to be investigated. Dr. Simson, of Glasgow, has made an attempt to restore some of them in a posthumous treatise concerning *Porisms*, printed in Latin. See also Phil. Trans. abr. vol. vi. part i. p. 76.

PORISTIC *method*, in *Mathematics*, is that which determines when, by what means, and how many different ways, a problem may be solved.

POROCELE, a word used by chirurgical writers for a callous hernia.

POROMPHALON, a word used by Hippocrates to express a callous concretion, or a sort of tophus formed in the region of the navel.

POROPHYLLUM, in *Botany*. See *Foreign* COLTSFOOT.

POROTICKS, a term used by the ancients for such medicines as would consume calluses.

PORPESSE, an English name given indiscriminately to two different fishes, the phocæna and the DOLPHIN.

Artedi, who has been very careful in bringing together the synonyms of authors, tells us, that this is properly the English name only of that species of the dolphin, the characters of which, according to his system, is, that the body is almost of a conic form, the back broad, and the body subacute. This species is the phocæna of Aristotle, the tursio or tursio of Pliny and Rondeletius, and the *delphinus phocæna* of Linnæus. Schonevelde calls it the small northern or oriental *delphin*, and the Swedes the *marsvin*.

fix is ranked among the cetaceous kind, and is the smallest fish of that tribe; the *porpesse*, properly so called, seldom exceeding five feet in length, in which it differs from the dolphin, a fish very often confounded with it, but which is frequently seen of ten or twelve feet in length. The snout of the dolphin is also much larger than that of the *porpesse*, which is another thing that may serve to determine their difference.

The *porpesse*, or *phocæna*, is of a roundish, not flat body, growing gradually smaller toward the tail; and just at the root of the tail it is a little flatted; its nose is long and pointed, and furnished with strong muscles, by means of which it is able to turn up the mud and sand, to seek after small animals; its skin is smooth, and but thin; its back is of a dusky bluish hue, almost black in some of the fish, and from the middle of the sides downwards, it is whitish; it has no gills, nor any aperture in the place of them; but in the middle of the upper part of its head, before the brain, it has a pipe or spiracle, in form of a half moon, through which this sort of fishes draws in their breath, and spouts out the water; this pipe terminates outwardly in one hole, but it is within divided into two parts by a bony septum, so as to represent two nostrils; but at its lower end it again becomes one hole, and opens into the mouth by a common orifice furnished with a very strong sphincter muscle, by means of which it may be shut and opened at pleasure; above this sphincter, the sides of the pipes are lined with a glandulous flesh, from which, when pressed, a glutinous liquor is forced out of certain little holes in it into the inside of the pipe; above the nostrils is a strong valve or membrane, which serves to stop the pipe at pleasure, and prevent any water from getting into it, but when the fish requires it within; within the fistula are six blind holes, having no outlet, four tending towards the snout, two placed above the valve, which stops the nostrils, and two beneath it; and two tending towards the brain, having a long and narrow cavity, which seems intended for the use of smelling, though, on opening the brain, no such olfactory nerves, or processus mamillares, as other animals are furnished with for this purpose, are to be found; its eyes are small; its auditory passages extremely minute, if any; its teeth, which are forty-eight in each jaw, also small; it has two fins on the breast, and one on the back, which are cartilaginous and flexible, not sharp or prickly as the ancients have represented them; and its tail is slightly forked, thus forming the figure of a crescent, and placed horizontally, like those of the cetaceous kind, not vertically, as in other fishes. The great contrivance of nature in this position of the tail in these fishes is, that it may supply the place of the hinder pair of belly-fins in other fish, those of the cetaceous kind having none such. These fins in other fish serve to balance the body, and keep it under water, and answer also in many respects to the hinder legs of a quadruped; and hence we see, that those fish which have long bodies, and have not this hinder pair of fins, nor the horizontal tail, cannot suspend themselves quietly in the water, but are forced to keep grovelling at the bottom. This is the case of eels, and all other fish of that kind; the use of respiration being as necessary to the *porpesse* as to quadrupeds, and its wanting this pair of hinder fins, so poise or elevate itself with, nature has abundantly provided against the mischiefs that would attend that defect, by giving it this transverse tail, by a sudden jerk of which it can in a moment throw itself up to the surface from the deep water. The whale, and all the cetaceous fishes requiring the use of respiration, have also this manner of raising their unwieldy bodies allotted them by nature, instead of the hinder pair of fins, which must have been inconveniently large to be capable of this office. Its lungs and heart are like those of quadrupeds. The *porpesse* has no gall-bladder, and thence authors have concluded that it has no gall; but this is too hasty a conclusion; for there is a duct which arises in the liver, and has a great many branches, and which, tending downwards, joins itself to the pancreatic duct; and these two, so united together, form a canal, or common duct, about four or five lines long, before they discharge their contents into the duodenum; from whence it appears that the *porpesse* has always a discharge of bile into the duodenum, though it is thin and diluted, and such as, in other animals, is usually called *hepatic bile*. The brain is large, and resembles that of man; and probably it has been an observation of this that has given occasion to the opinion of this animal having so great a share of wit and understanding, that has given rise to the story of Herodotus, that Arion was carried to shore on the back of one; and that of Pliny the Elder, of one of these fish so fond of a certain boy, that he used to carry him daily from Baiæ to Puteoli, across the sea to school, and wait to carry him back again at a certain time. Pliny the Younger gives us also a story of this kind in his Epistles. The tongue is flat, pectinated at the edges, and fattened down to the bottom of the mouth.

The blood of the *porpesse* is as warm to the touch as that of quadrupeds, and the blubber, or fat, which lies in great quantity under the skin, covering the muscular flesh of the back and sides, is to keep up the natural heat, and prevent the cold of the sea-water from chilling the circulating fluid. This blubber yields a great quantity of excellent oil.

The food of the fish seems to be speck, its living at the bottom of the water; for the common matter found in its stomach is the remains of fish that live in or on the bottom. The young *porpesses* are generally found to feed on the ammodyte, or sand-eels, and sea-worms.

This fish is common in all parts of the sea that washes these islands; but they are most numerous at the time when fish of passage appear, as mackarel, herrings, and salmon, which they *pursue* up the bays with the same eagerness as a pack of dogs does a hare. Its flesh is greasy, and now not valued; though it was a royal dish in the reign of Henry VIII. and continued in vogue in the reign of Elizabeth. Phil. Trans. N° 74 and 76. Lit. abr. vol. ii. p. 839, &c.

We have from Dr. Lister an account of the tooth of this creature, after death, giving an enormous wound. The accident happened to the doctor himself, and he relates it in Phil. Trans. N° 134. Abridg. vol. ii. p. 842.

PORPHYRIANA *ædes*. See AREIUS.

PORPHYRIANS, in *Ecclesiastical History*, an opprobrious name given to the Arians, by an edict of Constantine, at the council of Nice, in 325. Cap. 36. apud Hard. Concil. tom. i. p. 446.

That prince, publishing an edict against Arius and his writings, declares, that as Arius had imitated Porphyry in composing books against religion, he deserved to be noted with his infamy; and that, as Porphyry is become *the reproach* of posterity, and his writings suppressed, so he wills, that Arius and his followers be called *Porphyrians*, &c.

PORPHYRIO, in *Ornithology*, the name of a bird figured and described by all the natural historians from one another, but which, it seems, none of them ever saw; and there is some room to doubt whether there be in nature any such bird. According to the accounts we have of it, it appears to be one of the gallinula or moor-hen kind, and is all over of a fine deep blue, only the middle of the tail is at the extremity of a greyish white; its legs and feet are of a fine shining purple. There have been fame fabulous things related of it, as having five toes on each foot, and the like; but if there be any such creature, it seems to be a moor-hen of these remarkable colours. In the Linnæan system this is a species of *fulica*, or COOT.

PORPHYRIO *Americanus*, in *Ornithology*, a name by which some have called the QUACHILTO, a very beautiful species of Brasilian moor-hen.

PORPHYROGENITUS, in *Antiquity*, an appellation given to the children of the Eastern emperors; implying as much as *born in purple*.

Cedrenus will have the word to signify, *born in the purple palace*, or the *palace of porphyry*, a palace so called in Constantinople, wherein the empresses used to lie in. Others derive the appellation hence, that the imperial children, as soon as born, were wrapped in purple; others from this, that the chamber wherein they were born was hung with purple hangings.

This term is sometimes found on the medals of the lower empire, struck at Constantinople.

PORPHYRY, *porphyrites*, in *Natural History*, &c. a precious kind of stone, or marble, of a brownish-red colour, frequently interspersed with white spots; anciently brought from Egypt, and exceeding all other marbles in hardness.

It is used as the name of a genus of fossils, generally, but improperly, added to the marbles. These are stones of a plain uniform mass, and compact texture, like flint, spotted or veined, with separate concretions of quartz imbedded in all directions; giving fire with steel, not fermenting with acids, very slowly and difficultly calcining in a strong fire, and fusible.

Wallerius makes the *porphyry* a species of jasper. Pott classes the *porphyries* and jaspers under distinct genera. It is certain that the basis of the *porphyry* is of a compact, uniform substance, approaching nearly to that of the jasper; but in many properties they are different. The *porphyries* are always found in strata, the jaspers only in nodules: the former have always detached quartzose concretions imbedded in them; the latter are uniform, and never have concretions of a different nature.

Of this genus Dr. Hill enumerates three known species.

1. The purple kind, commonly known by the name of *porphyry*,

porphyry, among the workmen. 2. The hard red-lead-coloured kind, variegated with black, white, and green. And, 3. The very hard flesh-coloured one, variegated with white, green, and black.

The *purple porphyry* is a substance which has been well known, and highly esteemed, in all ages of the world. It has its name from the Greek πορφυρα, *purple*, as that remarkable colour always afforded a very obvious distinction for it, from the other kinds. It is of an extreme firm and compact structure, remarkably heavy, and of a fine strong purple, variegated more or less with pale red, and white, and with a small number of little, and generally disregarded, black flaky specks. Its purple is of all degrees, from the deep tinge of the violet to a pure claret colour; and its variegations are usually disposed in small spots, commonly small and disunited, but sometimes running into one another, and making large blotches. It is very difficultly cut, because of its very great hardness; but is capable of a very fine polish. It is found in great quantities in Egypt; and we find was had thence also in very early times. It serves us for stones for the apothecaries and colourmen, to grind or levigate their powders on, and on any other occasion where great hardness is required.

The *red-coloured porphyry* is also an extremely beautiful and valuable substance, but is hitherto unknown among our lapidaries. It has the hardness, and all the other characters of the purple *porphyry*, and greatly exceeds it in the variety of its colours. It is found in great plenty in the island of Minores, but has never yet been regarded as a stone worth importing into England.

The *flesh-coloured porphyry*. This is another very little known, but extremely beautiful stone; it is of an irregular, but very compact and firm texture, and of a pale flesh-colour, often approaching to white, and variegated with black, green, and white, in large blotches, from half an inch to an inch broad. It is found in immense flints in Arabia Petræa, and in Upper Egypt, and in detached nodules is common to almost all parts of the world. Germany abounds with them; and we have of them in many parts of England and Ireland. They are found in many places on our shores, and in some parts of Devonshire far from the sea. Hill's Hist. of Foss. p. 404 to 408.

Mr. Da Costa mentions two or three other species of green *porphyry* of different hues and variegations; and Fitzosmond takes notice of two exquisitely fine columns of black *porphyry* in a church at Rome; and black *porphyry* is also mentioned by Wallerius.

There are three famous *porphyry* pillars, or OBELISKS, in Egypt; one near Cairo, and the other two at Alexandria. The French call them *aiguilles*, the English *Cleopatra's needles*.

The art of cutting *porphyry*, practised among the ancients, seems lost. In effect, it is hard to conceive what kind of tools they must have used for the fashioning of those huge columns, and other *porphyry* works found in some of the antique buildings in Rome.

One of the most considerable pieces, now remaining entire, is a tomb of Constantia, daughter of the emperor Constantine, in the church of St. Agnes without the walls; ordinarily called *the tomb of Bacchus*, because of several boys represented herein, playing among the vine-leaves. Add to this Apollo's, and the busts of twelve emperors, all in *porphyry*, in the palace of the Thuilleries.
